In my paper on "Modern Machine Bookbinding" (published in the *Journal of the Royal Society of Arts* for February 17th) machines were described for practically all operations in commercial bookbinding, with the exception of those of glueing the back and applying the back-lining of mull and paper. I had a note of a patent for a machine adapted for these purposes, but as I was unable to learn whether or not the machine was actually on the market I did not refer to it. I have since definitely ascertained that several of these machines are working in American binderies. The machine is known as the Blauvelt Supering, Head-banding, and Back-lining Machine; it consists of a series of small machines, over which is a rotary carrier in which are assembled fourteen pairs of jaws for holding books. After a book has been fed to a pair of jaws, it is brought to the first glueing machine where the first coat of glue is applied to the back of the book; the book is then moved round to the super [*i.e.*, mull] apparatus, where the super is fed the proper width, cut to size, and applied to the back; it then passes round to the second glueing machine, where a second coat of glue is applied over the super; it is then carried to the head-banding machine, where the head-band is automatically made, cut to size, and attached to the book; it is subsequently brought to the paper-lining machine, where the paper-lining is pasted, cut to size and applied to the back, and finally the book is returned to the operator, who removes it. The machine is estimated to work at the rate of fourteen books per minute.

GEO. A. STEPHEN.

GENERAL NOTES.

THE POLYTECHNIC.—The Polytechnic, Regent-street, founded by Quintin Hogg in 1882, is being rebuilt at a cost of £90,000. The rebuilding fund was inaugurated by a grant of £20,000 from the London County Council, and a loan of £20,000 from the City Parochial Foundation. The £50,000 needed to complete the fund has been subscribed and promised by Lord Leith of Fyvie, the Governors, members and students of the Polytechnic, and other friends intimately associated with the institution, as a memorial to King Edward VII. The Polytechnic is one of the more important centres for the Society's examinations, presenting an average of about 350 candidates.

INTERNATIONAL CONGRESS OF THE APPLICATIONS OF ELECTRICITY, TURIN, 1911.—This Congress will be held at Turin from September 9th to 20th, under the auspices of the Italian Electrotechnical Association. The Committee have drawn up a list of over thirty subjects for discussion, which appears to be very exhaustive. It is hoped that the meetings will be strongly international in character, as the official delegates of the Electrotechnical Committees of various nations will be in Turin at the time, attending the first meeting of the International Electrotechnical Committee of Standardisation. Papers may be written in French, or in English, German, or Italian, when accompanied by a translation or summary in French, and all these languages will be admitted in the discussions. Persons wishing to offer papers or to learn further particulars of the Congress should communicate with the Secretary of the Committee of Organisation, Via S. Paolo 10, Milan.

FORESTRY IN BRITISH COLUMBIA.—The report recently published by the British Columbia Forestry Commission, which was appointed in 1909, is the first attempt at a systematic stocktaking of timber resources of Canada. It is estimated that British Columbia grows half the merchantable timber of the Dominion, its forest area being fifteen million acres, capable of yielding, under present methods of work, nearly two hundred billion feet super of timber. Of this area nine million acres are held under a special licence system. Options to cut timber during a twenty-one-year period on specified square miles of forest are granted, but at the same time the Provincial Government retains an effective control by reserving the right to fix from year to year the annual payments in rental and royalty to be made for the renewal of these options, and they also impose a reserve upon all remaining Crown timber. The Commission are of opinion that the demand for timber will raise the value of the British Columbian forests to heights now considered incredible, and that, with careful management, these resources should permanently relieve the people of the province from serious taxation.

NEW MEXICAN RUBBER PLANTS.—A resident in Mexico, who has for some years been experimenting in rubber-producing plants, has discovered, in the district of Manzanillo, a tree, a vine, and three plants which yield, according to the American Consul there, a first-class rubber. The tree is of quick growth, and can be propagated from slips put in the ground. Limbs that were thrown in the shade and left for six months germinated, and on being planted took root and are now growing well. Trees planted from slips will be large enough to prune in three years; limbs cut from the trees furnish the rubber; pruning can be done every year. This tree produces about 6 per cent. crude rubber. The three plants referred to grow wild,

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

Members are requested to take notice that the Ordinary Meeting on Wednesday, March 15th, will be held at **4.30 p.m.**, instead of 8 o'clock.

MONDAY, MARCH 13th, 8 p.m. (Cantor Lecture.) Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." (Lecture II.)

WEDNESDAY, MARCH 15th, **4.30 p.m.** (Ordinary Meeting.) Colonel CHARLES EDWARD CASSAL, V.D., F.I.C., "The Adulteration of Food." The Right Hon. the LORD MAYOR OF LONDON will preside.

THURSDAY, MARCH 16th, 4.30 p.m. (Indian Section.) CLAUDE HAMILTON ARCHER HILL, I.C.S., C.S.I., C.I.E., "Education in India." The Right Hon. Lord NORTHCOTE, G.C.M.G., G.C.I.E., will preside.

CANTOR LECTURE.

On Monday Evening, March 6th, Professor J. A. FLEMING, M.A., D.Sc., F.R.S., delivered the first lecture of his course on "Applications of Electric Heating."

The lectures will be published in the *Journal* during the summer recess.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1911 early in May next, and they therefore invite members of the Society to forward to the Secretary on or before Saturday, April 1st, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years :—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., "for his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty, Napoleon III., "for distinguished merit in promoting, in many ways, by his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by the abolition of passports in favour of British subjects."

In 1866, to Michael Faraday, D.C.L., F.R.S., "for discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S., "for the invention and manufacture of instruments of measurement and uniform standards, by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, etc., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I., "for services rendered to Arts, Manufactures, and Commerce by the realisation of the Suez Canal."

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in

aiding the establishment and development of International Exhibitions, the Department of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France, "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvements in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential services in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power — hydraulically — due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious manual labour."

In 1879, to Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S., "on account of the signal service rendered to Arts, Manufactures, and Commerce by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science to industrial pursuits."

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin, "for eminent services rendered to the Industrial Arts by his investigations in organic chemistry, and for his successful labour in promoting the cultivation of chemical education and research in England."

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S., "for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silkworms and domestic animals, whereby the arts of wine-making, silk production, and agriculture have been greatly benefited."

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., "for the eminent services which, as a botanist and scientific traveller, and as Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce by promoting an accurate knowledge of the floras and economic vegetable products of our several colonies and dependencies of the Empire."

In 1884, to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communications of North America, and have thereby rendered valuable aid to the commerce of the world."

In 1885, to Mr. (afterwards Sir) Henry Doulton, "in recognition of the impulse given by him to the production of artistic pottery in this country."

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham), "for the services he has rendered to the textile industries, especially by the substitution of mechanical wool combing for hand combing, and by the introduction and development of a new industry—the utilisation of waste silk."

In 1887, to Her Majesty Queen Victoria, "in commemoration of the progress of Arts, Manufactures, and Commerce throughout the Empire during the fifty years of her reign."

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S., "in recognition of the value of his researches in various branches of science, and of their practical results upon music, painting, and the useful arts."

In 1889, to John Percy, LL.D., F.R.S., "for his achievements in promoting the Arts, Manufactures, and Commerce through the world-wide influence which his researches and writings have had upon the progress of the science and practice of metallurgy."

In 1890, to Dr. (afterwards Sir) William Henry Perkin, F.R.S., "for his discovery of the method of obtaining colouring matter from coal tar—a discovery which led to the establishment of a new and important industry, and to the utilisation of large quantities of a previously worthless material."

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S., "in recognition of the manner in which he has promoted several important classes of the Arts and Manufactures, by the application of Chemical Science, and especially by his researches in the manufacture of iron and of steel; and also in acknowledgment of the great

services he has rendered to the State in the provision of improved war material, and as Chemist to the War Department."

In 1892, to Thomas Alva Edison, "in recognition of the merits of his numerous and valuable inventions, especially his improvements in telegraphy, in telephony, and in electric lighting, and for his discovery of a means of reproducing vocal sounds by the phonograph."

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S., "for their joint services to scientific agriculture, and notably for the researches which, throughout a period of fifty years, have been carried on by them at the Experimental Farm, Rothamsted."

In 1894, to Sir Joseph (afterwards Lord) Lister, F.R.S., "for the discovery and establishment of the antiseptic method of treating wounds and injuries, by which not only has the art of surgery been greatly promoted, and human life saved in all parts of the world, but extensive industries have been created for the supply of materials required for carrying the treatment into effect."

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his metallurgical researches and the resulting development of the iron and steel industries."

In 1896, to Professor David Edward Hughes, F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his numerous inventions in electricity and magnetism, especially the printing telegraph and the microphone."

In 1897, to George James Symons, F.R.S., "for the services he has rendered to the United Kingdom by affording to engineers engaged in the water-supply and the sewerage of towns a trustworthy basis for their work, by establishing and carrying on during nearly forty years systematic observations (now at over 3,000 stations) of the rainfall of the British Isles, and by recording, tabulating, and graphically indicating the results of these observations in the annual volumes published by himself."

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S., "in recognition of his numerous and most valuable applications of Chemistry and Physics to the Arts and to Manufactures."

In 1899, to Sir William Crookes, F.R.S., "for his extensive and laborious researches in chemistry and in physics—researches which have, in many instances, developed into useful practical applications in the Arts and Manufactures."

In 1900, to Henry Wilde, F.R.S., "for the discovery and practical demonstration of the indefinite increase of the magnetic and electric forces from quantities indefinitely small—a discovery now used in all dynamo machines—and for its application to the production of the electric searchlight, and to the electro-deposition of metals from their solutions."

In 1901, to His Majesty King Edward VII., "in recognition of the aid rendered by His Majesty to Arts, Manufactures, and Commerce during thirty-eight years' Presidency of the Society of Arts, by undertaking the direction of important exhibitions in this country, and the executive control of British representation at International Exhibitions abroad, and also by many other services to the cause of British Industry."

In 1902, to Professor Alexander Graham Bell, "for his invention of the telephone."

In 1903, to Sir Charles Augustus Hartley, K.C.M.G., "in recognition of his services, extending over forty-four years, as Engineer to the International Commission of the Danube, which have resulted in the opening up of the navigation of that river to ships of all nations, and of his similar services, extending over twenty years, as British Commissioner on the International Technical Commission of the Suez Canal."

In 1904, to Walter Crane, "in recognition of the services he has rendered to Art and Industry by awakening popular interest in Decorative Art and Craftsmanship, and by promoting the recognition of English Art in the form most material to the commercial prosperity of the country."

In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S., "in recognition of the influence which his researches, directed to the increase of scientific knowledge, have had upon industrial progress, by facilitating, amongst other scientific applications, the provision of accurate electrical standards, the production of improved lenses, and the development of apparatus for sound signalling at sea."

In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S., "for the important part he took in the invention of the incandescent electric lamp, and for his invention of the carbon process of photographic printing."

In 1907, to the Earl of Cromer, G.C.B., O.M., G.C.M.G., K.C.S.I., C.I.E., "in recognition of his pre-eminent public services in Egypt, where he has imparted security to the relations of this country with the East, has established justice, restored order and prosperity, and, by the initiation of great works, has opened up new fields for enterprise."

In 1908, to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S., "for his investigations into the liquefaction of gases and the properties of matter at low temperatures—investigations which have resulted in the production of the lowest temperatures yet reached, the use of vacuum vessels for thermal isolation, and the application of cooled charcoal to the separation of gaseous mixtures and to the production of high vacua."

In 1909, to Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S., "in recognition of his long-continued and valuable researches into the nature and action of explosives, which have resulted in the great development and improvement of modern ordnance."

In 1910, to Madame Curie, "for the discovery of radium."

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A Meeting of the Colonial Section was held on Tuesday, February 28th, the Right Hon. LEWIS HARCOURT, M.P., Secretary of State for the Colonies, presiding.

Lord BLYTH, Chairman of the Colonial Section, announced that letters had been received from the Duke of Abercorn, the Earl of Selborne, Lord Curzon of Kedleston, Lord Ampthill, and many other gentlemen, regretting their inability to attend the meeting from various causes.

The CHAIRMAN said he had stolen an uncovenated hour from the House of Commons because he could not resist the temptation of the invitation offered to him to attend the meeting, and the treat which he knew he should enjoy in the paper which was to be read. He was happily aware that none of those present had attended for the purpose of listening to the platitudes or the prosing of a politician, and, therefore, his own part in the proceedings would be very brief. He was told on arriving at the meeting that it was part of his duty to introduce the author, Sir Richard Solomon. He proposed to do nothing of the sort. He could not imagine anything more ludicrously inappropriate than that he should have the temerity to attempt to introduce a gentleman whose name was a household word in two continents, a gentleman whose services were fully recognised in England—services which he had rendered to the great Union of South Africa by his life, by his residence in the country, and by the work which he was happily continuing in the position he now occupied in London. No such introduction could be necessary, and as he was quite certain that the audience was anxious to hear the information which the author was so fully and admirably fitted to convey, he would at once call upon him to read his paper.

The Paper read was—

THE RESOURCES AND PROBLEMS OF THE UNION OF SOUTH AFRICA.

By the Hon. Sir RICHARD SOLOMON, K.C.B., K.C.M.G., K.C.V.O., K.C.,

High Commissioner for the Union of South Africa.

The Union of South Africa embraces an area of 420,000 square miles, or twice the size of France. It has, according to the last census, taken in 1904, a European population of about 1,120,000 and a coloured population of over 4,000,000, of whom approximately 3½ millions are pure aboriginal natives in different stages of civilisation.

It is based on a written constitution embodied in the South Africa Act passed by the Imperial Parliament in 1909, under which the self-governing colonies of the Cape of Good Hope, Natal, Transvaal, and Orange Free State, were brought into a legislative Union under the Crown with one Government and one Parliament, each of these colonies becoming a province of the Union.

It is with the resources and problems of the Union that this paper attempts to deal. I shall not make any reference to the native protectorates, now under the direct control of the Crown, nor to Southern Rhodesia, under the administration of the British South Africa Company, beyond expressing the general opinion that, in course of time, all these territories will be included in the Union of South Africa, which will then comprise the whole of British Africa south of the Zambesi.

Within the time at my disposal this afternoon I cannot attempt to make anything like an exhaustive survey of the resources of the Union, nor of the future problems which lie before it. All I can venture to do is to give some general idea of its wealth as a producing country, and of the difficulties of some of the problems which its Government and Parliament have to solve in the near future.

It is unnecessary to say much about the mineral resources of the Union. They have for years past attracted much public attention in this country, more especially the mines in the Witwatersrand district of the Transvaal, which produce 95 per cent. of the gold exported from the Union of South Africa. Sixty miles of reef within this district are now actually being worked. Discovered in 1886, they differ from gold-bearing reefs in other parts of the world in the consistency of the sedimentary deposits and the extraordinarily even distribution of the gold; so that, to quote from an article by Mr. Lionel Phillips, one of the leaders of the mining industry, which appeared in a special edition of the *Times*, published on the day of the opening of the first Parliament of the Union by H.R.H. the Duke of Connaught, "large sums of money can be invested with confidence in opening up mines on a large scale and equipping them with extensive appliances which would not be justifiable in quartz mines. The Witwatersrand reefs are poor in yield compared with those in some other gold-producing countries. They average about 29*s*. per ton, while in the reefs in Australia and New Zealand the yield varies from 55*s*. to 140*s*. per ton; in India from 38*s*. 6*d*. to 108*s*., and in the United States from 127*s*. 9*d*. to 200*s*. But, nevertheless, as a field for the investment

of capital, the Witwatersrand mines are unrivalled because of the reliability of the deposits."

Another characteristic of gold-mining in the Transvaal is mentioned by Mr. Phillips in the same article. The temperature of the earth downwards varies in different parts of the world, but the normal rise is about one degree for every sixty-five feet of vertical depth. In the Witwatersrand district the temperature only rises at the rate of one degree for every 255 feet. It is, therefore, probable that mining will be carried on to a much greater depth in the Witwatersrand mines than anywhere else in the world.

Since 1887, when the Witwatersrand district of the Transvaal first commenced to produce gold, to the end of 1909, the value of the precious metal produced by the Transvaal was £258,000,000. In 1887 the output was only 0·78 per cent. of that of the whole world; it is now about one-third of it. The total dividends distributed by the gold-mining companies in the Transvaal during the year 1910 amounted to £9,118,858.

Next in importance to gold in the way of minerals in South Africa are diamonds. South Africa is the only place in the world where diamond mines or pipes, going vertically downwards to an unknown depth, have ever been discovered. In Brazil, which, before the discovery of mines in South Africa, was the only producer of diamonds, no mine or pipe has ever been found. The precious stones were found in gravel beds, which were only of a small depth and have now been practically worked out. At present within the Union of South Africa there are diamond mines in Kimberley, in the Orange Free State, and in the Transvaal. The value of the diamonds produced since their discovery in 1870 is about £133,000,000. The supply, as far as we can see, is inexhaustible, and any demand can be met; but the world can only take a limited quantity per annum, and the output is, therefore, controlled as far as possible so as not to glut the market and reduce the value of this precious stone.

Besides gold and diamonds, South Africa is rich in base minerals. Coal is found in every province of the Union sufficient for all its requirements. During the year 1910 the Union imported about 66,000 tons of the value of £37,000, while it exported 1,475,000 tons of the value of £991,000. From this it will be seen that practically the whole of the coal used by the gold-mines and diamond-mines, by 7,000 miles of railways, by all the other industrial undertakings in South Africa, as well as for domestic purposes, is supplied from collieries within the Union; while at the same time an export trade in that mineral is being developed. At present the value of the coal produced within the Union is nearly £2,000,000 a year, and the Government take in railway rates on its transport about £100,000 a month. Natal alone, where coal-mining may be described as the principal industrial asset, produced in 1909 about 1,750,000 tons. Natal coal will, in all probability, find a permanent market in India and Ceylon. The locomotive superintendent of one of the great railways in India, after visiting the South African coal-fields, reported that Natal coal was from 8 to 10 per cent. better than the bulk of Bengal coal, and advised the placing of substantial orders for the former; last year one of the Natal collieries secured a contract for 5,500 tons of coal for the Ceylon Government Railways.

Copper is also produced within the Union, principally by the mines in Namaqualand, the total output of which up to the end of 1909 was of the value of £7,500,000. Other copper-mines, such as the Messina, near the Limpopo, are being developed in other parts of the Union, while the exploitation of a number of tin properties in the Waterberg district of the Transvaal gives encouragement to the view that in the near future tin will be a substantial export of the Union. Iron is found in large quantities in South Africa, and a company has now been formed and will shortly start operations in the Transvaal for the main purpose of converting scrap-iron, of which an immense quantity has collected, into steel, but which will also experiment on the iron ore of the country.

The discovery of minerals has brought about a great change over the face of South Africa, and has played an important part in its history and in the development of its resources generally. The gold and diamond mining industries have furnished the inducement and the capital for the construction of railways, harbours, and other public works. They have given vitality to the coal-mining industry, and have enabled the Government to incur large expenditure for the benefit of agriculture, the permanent industry of South Africa.

Up to 1870, when the diamond mines in Kimberley were discovered, the only railway lines which existed in the whole of South Africa south of the Zambesi were a line of fifty-seven miles from Cape Town to Wellington, opened for public traffic in 1863, a short line of eight

miles from Salt River to Wynberg, and a line two miles long from Durban to the Point. To-day, owing to the development of the diamond-mining industry in Kimberley, and of the gold mines in the Transvaal especially, there are within the Union 7,045 miles of railway in use and 900 miles in actual construction. The South African Railways to-day is one of the largest centralised railway undertakings in the world.

I have no desire to weary you with a mass of figures, but the following will be interesting. The capital spent on harbours and railways within the Union amounts to £89,000,000, of which £11,600,000 were paid out of their revenues, leaving £77,400,000 as representing the loan capital of the Railways and Harbours Administration, on which that Administration pays the Government of the Union interest at the rate of 3½ per cent., the Government being responsible for the payment of that debt, which forms part of the total debt of the Union, estimated at £116,037,000. Under the Constitution of the Union of South Africa, after the expiration of four years the income derived from railways and harbours will be expended solely on them, and will not be available for ordinary expenditure. The railways are to be administered by a Board of Commissioners appointed by the Governor-General in Council "on business principles, due regard being had to the agricultural and industrial development of the Union, and the promotion by means of cheap transport of the settlement of an agricultural and industrial population in the inland portions of the Union."

According to the financial statement of the Minister of Railways during the present session of Parliament, the gross revenue from railways and harbours for the year ending March 31st, 1910, was over £1,000,000 per month.

In 1873, about two years after the discovery of diamonds in Griqualand West, but before that discovery had had time to produce any substantial effect on the prosperity of South Africa, the number of passengers carried on the railways was 436,000 in round numbers, while in 1909 it was 15,350,000; the goods traffic in the former year was 66,000 tons, while in the latter year it was 1,350,000 tons. In 1873 the net earnings of the railways in South Africa were £65,700, while in 1909 the earnings of the railways in the Union alone, after payment of working costs and interest on capital, amounted to £3,129,000. These figures show what railways have done for the development of South Africa, and what an important factor they have been in a country in which there are no navigable rivers or deep estuaries. They are the only means of communication between the ports and the interior, for the day of the ox-waggon has passed away.

In salaries and wages the gold mines in the Witwatersrand district alone paid over £11,000,000 during the year 1909, and I do not think it is an exaggeration to say that the wages earned annually by native miners within the Union amount to quite £5,000,000, which is practically all spent in the different districts in which they reside. "It will perhaps be realised, therefore," says a writer on the subject of native labour in South Africa, "what prospects there are in the development of trade and commerce with the natives. The extent to which our commercial prosperity in South Africa depends on the well-being and success of the native labourer is scarcely realised. Thirty years ago the great majority of aboriginal natives did not work at all. To-day, owing to the mines, the majority of them spend half the time between the ages of twenty and forty in intermittent periods of work. Unfortunately, the labour statistics of the country are very imperfectly kept, but there are probably at present nearly 750,000 natives working for European employers within the Union." The gold-mines in the Transvaal alone employ about 200,000, the diamond-mines about 42,000, the coal-mines about 20,000, and about 19,000 are employed on the railways and harbours. When it is remembered that the total native population in Africa south of the Zambesi is about 7,000,000, of whom there are probably not more than 1,400,000 males over the age of sixteen capable of doing work, it can hardly be said with any justification that the natives are a lazy people. The desire for work is steadily though slowly increasing. Economic and social causes are undoubtedly tending to make the native more of a continuous labourer than he is at present, but it is difficult to predict how long the transformation will take.

The effect of the gold-mines on native life is not entirely a happy one. The death-rate is, unfortunately, still high. The last Government returns issued show an actual death-rate of thirty-three to the thousand, and this leaves out of account those who contract miners' phthisis and go home and die. The conditions on the mines are, however, improving, and the increase from 142,000 native labourers in 1904 to 200,000 to-day is largely due to that improvement.

The whole system of recruiting has been revolutionised, and labour agents are controlled by legislation in each province. The conditions under which the natives travel to the mines have been greatly ameliorated. Rest houses have been established on the road, and better railway accommodation provided. The rations supplied have been improved and varied, and a Government director of labour has been appointed with a staff of over 100 inspectors, interpreters, medical officers, and clerks for the supervision and control of natives, inquiring into their complaints and exercising a general supervision over their comfort and welfare. Magistrates from the Transkeian territories and other recruiting areas personally visit the mines and inquire into the complaints of native labourers, and are thus able to explain to the natives in their territories from personal experience the actual conditions under which the native miners work and live. The result is that, whereas in 1906 there were only 2,600 natives from the Cape province employed on the Rand mines, in 1910 there were 80,000.

For the year 1909 the Transvaal gold-mines spent £10,000,000 in round numbers on material, machinery, and explosives, of which articles producible in South Africa, such as explosives, candles, cement, etc., amounted to £4,000,000. These figures give some idea of the importance of the mines in the Transvaal to both British and South African producers and manufacturers.

For the year 1910 the value of the oversea imports into the Union, excluding specie, was about £34,000,000 in round numbers, and that of the oversea exports about £52,000,000, including gold and diamonds. In 1873 the imports into Cape Colony and Natal together amounted to only £2,800,000, and the exports from the two colonies together were valued at £2,900,000. I have not the figures for the Transvaal and Orange Free State, but the imports into and exports from those two States would not be anything like as large as in the case of Cape Colony, so that it is quite safe to say that in 1873 the imports into the four colonies and states now forming the Union, did not exceed £4,000,000 a year, and the exports from them oversea must have been considerably less. In other words, it may be said that the present trade of the Union is at least ten times as great as was the combined trade of the colonies and states now included in it, about the time when the diamond-mining industry was first established.

While the history of the material progress of South Africa during the last forty years has been substantially a history of the discovery and development of its minerals, I venture to think that an era of great agricultural prosperity has now commenced, and that before many years have passed South Africa will be looked upon, not only as a rich mineral country, but as one of the principal agricultural countries of the world.

The progress made during the last few years has been remarkable. The advantages of scientific farming, of adopting the most modern methods of cultivation, and of dealing with diseases of animals and pests are being fully appreciated.

The establishment of land banks, agricultural schools, and experimental farms; the encouragement and assistance given to co-operative associations and agricultural societies; the equipment of the Government Agricultural Department with the best experts it is possible to obtain, to advise farmers on the treatment of animal diseases, and the proper cultivation of the soil, are only instances of the efforts which are being made by the Government for the development of the agricultural resources of the country. These efforts, initiated by Lord Milner's Crown Colony Administration in the Transvaal, are strongly supported by Parliament, which votes over £700,000 a year for that purpose.

There was a time when South Africa imported nearly all its foodstuffs, and though it still imports many articles which can and ought to be grown and manufactured locally, everyone is sanguine that, within a few years, not only will the Union be self-supporting, but it will be a substantial exporter of food. If we take the year 1906 as the first year after the war when the commercial, agricultural, and mining industries had settled down to normal conditions, and were no longer appreciably affected by the war, we find that the total agricultural exports from the four colonies now forming the Union of South Africa were £6,145,000 in value, while in 1910 they amounted to £10,750,000, or an increase in four years of about 75 per cent.

Again, comparing the imports for 1906 with those of 1910, it will be found that while the total value of the imports, excluding specie, had increased by nearly £4,000,000, the amount of foodstuffs imported in the former year into the four colonies now forming the Union amounted to £7,770,000 in value, while the amount imported in 1910 had fallen to £5,900,000, showing that the products of South Africa had replaced a quantity of foodstuffs which had been previously imported.

Wool is the most important of all the agricultural exports from the Union. In 1826 the value of the quantity exported from South Africa was only £545. In 1841 it reached £200,000. Rapid progress was made from year to year, though in some years there was a set-back owing to droughts, diseases among sheep, and other causes. Some time elapsed after the war before the farmers in South Africa could replenish their flocks, but they are doing so now with great success. The country is well stocked with sheep of a good class, thousands of thoroughbred animals are being imported from France and Australia, and very high prices are being paid for good stud rams.

The value of the wool exported from the Union of South Africa during last year was £3,831,000. The Government has, through its experts in South Africa and the Trade Department in London, done much to instruct the farmers in the clipping, sorting, and baling of their wool for the home market, with the result that considerable improvements have been effected in the "get up" of South African wool.

The Angora goat is one of the successes of the Cape farmer, and the value of Angora hair exported from the Cape province of the Union in 1910 was £903,000. I believe I am right in saying that the only other country which produces mohair is Turkey, and though Cape mohair may be inferior to the finest quality exported from that country, it more than makes up by its larger output. The South African Angora goat has now a great reputation, and its exportation oversea is prohibited by law.

Cattle-breeding is another great agricultural industry in South Africa, and notwithstanding the fact that the country was almost denuded of cattle during the war, and has had since to contend against the ravages of East Coast fever—which is now being steadily stamped out by the persistent and scientific efforts of the Government, loyally supported by Parliament—the number of horned cattle within the Union is probably more than 4,000,000. A few years ago a large quantity of frozen meat was imported into South Africa owing to the dearth of cattle. To-day South Africa can supply all its own requirements in meat, and will, in the near future, be an exporter of it. Co-operative creameries have been established, with the result that, in the Orange Free State alone, the amount of butter made has increased from eight tons in 1905 to 1,000 tons, of the value of £125,000, in 1910. These creameries have given a great impetus to cattle-breeding, and South Africa may fairly look forward to becoming a substantial exporter of butter.

Efforts have been made since the war to establish a distinct breed of South African horse, but that object has not yet been attained. The late Transvaal and Orange Free State Governments maintained a stud of from twenty to thirty horse sires, mainly thoroughbred, which were leased to farmers at reasonable prices. About twenty years ago the Cape Government imported a number of hackney sires, which were sold out of hand on arrival and distributed through the country. South African conditions favour the production of the mounted infantry type, which is really the South African horse, and horses suitable for mounted infantry find a ready sale at about £25 each. Horse-breeding is now extensively carried on in different parts of the Union.

One of the most important agricultural industries in the Union, judged from the present value of its exports, is ostrich farming. Statistics show that in 1826 feathers to the value of £2,800 were exported, consisting almost entirely of what was plucked from the wild ostrich after killing it. The industry has for years past been pursued in a much more intelligent manner, and the farmers engaged in it realised long ago the difference in value between inferior and superior feathers, and different strains of birds were bred, which are known by the names of well-known ostrich breeders.

The ostrich feather industry is surrounded by many problems, and the Trade Department in London of the Union Government must be constantly on its guard to advise farmers of any changes in fashion, and must also keep a sharp eye on the supply and demand of the markets in connection with special classes of feathers.

The principal ostrich-breeding districts within the Union are in the Cape Province. The total quantity of feathers exported in 1910 was of the value of £2,273,000, which were almost all sold on the London market. As in the case of the Angora goat, the exportation oversea of the ostrich and also the ostrich egg is prohibited by law.

During the last fifteen years strenuous efforts have been made to develop an export trade in fresh fruit from South Africa, which have met with considerable success.

In the year 1900 the total quantity of fruit exported in ships' cold storage amounted to 17,336 boxes. Ten years later it exceeded 200,000 boxes, the total value of which was

about £35,000. The principal fruits now exported from the Union are grapes, plums, peaches, nectarines, apricots, and pears. The export of citrus fruit, comprising chiefly oranges and naartjes (mandarines) is increasing rapidly, and may be said to have passed the experimental stage. Oranges are grown in all the Provinces of the Union. They arrive in the London market at a time of the year when there are no supplies from other parts of the world, and excellent prices are obtained for them.

Experiments, under Government auspices, are still carried on with a view to ascertaining the best methods of packing and transportation. The policy of the Government is not to subsidise the fruit export trade by cash contributions, but to help the producers as much as possible by means of advice, through the Agricultural Department of the Union and the Trades Commissioner in London, as to the best methods of cultivation, the best types of fruit, picking, packing, and the precise requirements of the oversea markets.

In the cultivation of maize (known in South Africa as mealies) lies one of South Africa's greatest potentialities. It is the staple crop of a large part of each of the Provinces of the Union, and, besides being excellent as food for human beings, may be used for starch, glucose, animal food, and spirits. Under the most helpful guidance of the Government, the export of maize is increasing yearly. It has grown from 41,400 tons, of the value of £184,000, in 1907 to 160,000 tons, of the value of £700,000, in 1910, of which 43 per cent. was shipped to the United Kingdom, 29 per cent. to Belgium and Holland through Antwerp, and 27 per cent. to Germany through Hamburg.

As a field for maize cultivation, South Africa is unrivalled, and the industry offers great attractions to cultivators with energy and enterprise. The climate is ideal, with an ample rainfall in the summer months during the growth of the grain, and a dry winter for harvesting it. No country in the world can produce a finer quality of maize. The corn trade speak in no uncertain way of their preference for South African maize to that of other countries.

The world's annual consumption of this product is at present over 90 million tons, the British market alone absorbing over two million tons a year. The opportunities for expansion are unlimited, and the Union of South Africa may be relied upon in the future to contribute a large portion of this colossal trade.

Maize, however, is not the only cereal which can be successfully grown in South Africa. Oats have for many years past been produced in large quantities, more especially in the Cape Province, and an increasing quantity is being exported to the British market. Wheat is also grown in certain parts of the Union, but in the past has suffered somewhat from the ravages of rust. It is confidently hoped that the investigations which are being made by the expert agriculturists of South Africa will result in the production of a wheat which will overcome this difficulty. When this is accomplished, there is no reason why South Africa should not, within a comparatively short time, be able not only to satisfy its own demands, but also to export to other countries. Barley, Kaffir corn (a kind of Indian millet), and many other descriptions of produce are grown in South Africa owing to the richness of its soil and the variety of its climate. In fact, almost every known cereal can be produced.

While farming in South Africa has many advantages, such as a healthy climate, a productive soil, and cheap labour, it must be admitted that it is subject to many disadvantages, in the way chiefly of droughts, diseases of animals, and insect pests. The advantages, however, counterbalance the disadvantages, and, as a rule, a man with average ability and energy, possessed of a moderate capital, who applies himself judiciously to farming pursuits for a period of from five to ten years, should by the end of that time not only have a comfortable income derived from the cultivation of his land, but the capital value of his holding and of his stock should become increased to a marked degree.

In addition to what I have already mentioned, there are other South African products which form a substantial part of the export trade of the Union. The black wattle, introduced from Australia, yields a high percentage of tannin, which is used in the tannage of leather, and is now extensively grown in Natal. There are at present about 200,000 acres under cultivation, giving a return of 24,000 tons of bark. The value of the quantity at present exported is nearly £200,000 per annum, almost the whole of which goes to the Continent of Europe, as English tanneries do not yet consider it to be of sufficient regular quantity and supply to warrant them putting down plant to deal with it.

Transvaal tobacco has a high reputation among smokers in South Africa, and efforts

are now being made to produce a superior leaf. The Government of the Union have imported American experts and have established experimental stations and large tobacco warehouses, where the leaf grown by the farmers will be treated by the latest and best methods, and afterwards sold to manufacturers in the open market. The production of tobacco is rapidly increasing, improvement both in its cultivation and treatment is most marked, and the future prospects of the industry are very bright.

Cotton-growing is quite a new industry, although, during the last four or five years, a number of farmers in the Zoutpansberg District of the Transvaal have been growing this crop in a small way. Last season experiments were made in growing cotton at Tzaneen, Rustenberg, and Barberton, and the results obtained surprised the most sanguine expectations; for the crops from American seed were disposed of in the Liverpool market at prices varying from one penny to twopence per pound higher than that paid for American upland varieties. The normal Transvaal season is specially suited to cotton-growing, as the rainy period from October to April is of sufficient duration for the full growth and development of the plant, while the crop can be harvested during the dry season from May to August. The largest cotton belt in the Transvaal lies in the Zoutpansberg District, and the railway now being built, which will unite Pietersburg with Delagoa Bay, will open up a large and suitable region for this industry.

Cotton-growing has also been cultivated in parts of the Cape Province, and a company has already been formed to take up land on the coast between East London and St. John's River for that purpose. It is said that that part of the country is in every way, both as regards soil and climate, excellent for cotton-growing.

Forty or fifty thousand acres in Natal are under sugar-cane, and manufactories have been established there for years. The annual production of sugar is about 74,000 tons, while the quantity required for the whole of South Africa is a little over 100,000 tons, so that about 25,000 tons are imported. It is a highly protected industry, as not only is imported sugar subject to a Customs duty of five shillings per 100 lb., but Natal sugar has preferential railway rates for its conveyance. Over four thousand acres in Natal are under tea cultivation, the production of which during 1910 was about 800 tons, nearly the whole of which was consumed locally.

Viticulture is one of the oldest South African industries. Established first in the days of the early Dutch settlers, it has become a most important factor in the development of the western districts. It maintains something like 80,000 people. In 1909 (the last year for which I have the figures) about 3½ million gallons of wine were produced, and there is no doubt of the great improvement in recent years, especially in the light wines made at the Cape.

Lord Blyth, an eminent authority on viticulture, was asked by the late Government of the Cape Colony, two years ago, to visit South Africa and report to them on the prospects of this industry. In his most valuable memorandum on the subject, he states his opinion that natural wines, both white and red, can be produced in many localities of the Cape Province of a sufficiently good quality to satisfy the wants of a large proportion of the wine-drinking population of the Union, and that there is also a fair prospect of a limited quantity of wines of the port wine type being exported to other parts of the world. Lord Blyth, however, does not appear at all sanguine of any great export trade in Cape wine being developed, and is evidently of opinion that the wine farmers in the Cape Colony should look to their own market as the substantial outlet for the bulk of the wine produced in South Africa, and should give more attention to the cultivation of grapes for export as fresh fruit and as raisins, for which there is an ever-increasing demand in every part of the world.

I have dealt at such length with the resources of the Union that I am afraid I have left myself very little time to discuss some of its problems.

Many questions relating to the constitution of the Legislature, such as plural voting, equality of votes, redistribution of seats, the powers of the Upper Chamber of Parliament, and the settlement of conflicts between it and the Lower Chamber, which are still the subjects of controversy in this country, have fortunately been settled for the Union of South Africa in its written Constitution, under which effect is given to the principle of one man one vote, and one vote one value, by providing for one-member electoral divisions, each containing, as far as possible, with due regard to density or sparsity of population, physical boundaries, etc., the same number of registered voters. The automatic increase of the number of members of the House of Assembly assigned to each Province, in proportion to the increase in its number of electors, is based on certain definite rules, thus avoiding any necessity in the future of introducing into the Legislature such a contentious measure as a Redistribution of Seats Bill.

The Senate or Upper House of the Legislature, one-fifth of whose members were nominated by the Governor-General in Council, and four-fifths were elected by the Parliaments of the Colonies (now Provinces) prior to their dissolution on the taking effect of the Union, has all the powers of legislation enjoyed by the Lower, or popularly elected House, except in respect of a money bill, which it can neither originate nor amend, though it may reject it. Provision is made in the Constitution for settling a conflict between the two Houses in respect of a Bill passed by the Assembly, by a joint sitting of their members. The Bill passed at such sitting becomes law.

The settlement of these important matters in the Constitution itself is of the greatest importance; it avoids the conflicts and the unsatisfactory compromises which would inevitably have taken place had such matters been left to the decision of Parliament.

It must be admitted, however, that there are questions of first-class importance for which only a makeshift solution has been provided in the Constitution, and to which the attention of the Parliament of the Union must in the near future be given. Among them is the question of the parliamentary franchise. In a Legislative Union, the qualification for an elector ought to be the same throughout. This is not so, however, in the Union of South Africa, for, under its Constitution, owing to circumstances which could not be avoided, the qualification for a parliamentary voter in a province remains what it was before union was established, and differs materially from that in the adjoining province. Whether uniformity will be created by adopting for the whole of the Union, as far as the European population is concerned, adult male franchise, which exists in the Transvaal and Orange Free State, or a property franchise, which exists in the Cape of Good Hope and Natal, I do not attempt to predict. Much may be said in favour of both; but as, by the adoption of the latter, many persons in the Transvaal and Orange Free State will become disfranchised, it is not improbable that there will be a strong feeling in favour of giving every adult European male throughout the Union the parliamentary vote. A more difficult question arises in respect of the admission of coloured persons to the franchise, from which they are at present excluded in the provinces of the Transvaal and Orange Free State, and practically in Natal. In the Cape of Good Hope, however, no distinction was ever made between Europeans and coloured persons in this respect. The qualification for the parliamentary franchise in that colony was prescribed by law, and whoever possessed it became entitled, without distinction of race or colour, to be registered as a voter. The South African Constitution not only continues this law, but provides that, though the Parliament of the Union may in future prescribe by statute the qualification which shall be necessary to entitle persons to vote at the election of members of the House of Assembly, yet no such law shall disqualify any person in the province of the Cape of Good Hope now entitled to the franchise, by reason of his race or colour only, unless it was passed at a joint sitting of the members of both Houses of Parliament, and at its third reading was agreed to by not less than two-thirds of the total number of members of both Houses.

I shall not speculate on what action is likely to be taken, in respect of this important question, by the Parliament of the Union of South Africa. Uniformity in native policy was one of the reasons for the union of the self-governing colonies, but it cannot be brought about in a hurry. It is difficult, however, to see how South Africa can go backwards on this question, and produce uniformity by depriving the coloured persons of the Cape of Good Hope of privileges which they have enjoyed for more than half a century, and which they have, on the whole, exercised wisely.

One of the most exacting tasks of the Government and Parliament of the Union will be the settlement of its Civil Service, consisting now of the staffs of four different administrations. A commission has been appointed, in terms of the Constitution, to make recommendations not only for such reorganisation and readjustment of the departments of the Public Service as may be necessary, but also in regard to the assignment of officers to the several provincial administrations. Upon receipt of this report, the Governor-General in Council will assign to each province such officers as may be necessary for the proper discharge of the services reserved or delegated to it. In addition to this temporary commission, appointed for a special purpose, the Governor-General in Council is authorised and required by the Constitution to appoint a permanent Public Service Commission, with such powers and duties relating to the appointment, discipline, retirement, and superannuation of public officers, as Parliament shall determine. It is confidently anticipated that the result of the appointment of these two commissions will be the

establishment of an efficient Civil Service, with security of tenure, pensions, and promotion, and, above all, absolutely independent of the favours of political parties.

The amalgamation into one legislative Union of four self-governing colonies, in which different laws, even on matters of common concern to the whole of South Africa, were developed, means a vast amount of work in establishing anything like legislative uniformity. The process must be slow, but there ought to be no delay in establishing uniformity in the different laws which now prevail on such important subjects as taxation, the solemnisation of marriages, patents, trade-marks, joint-stock companies, and commercial documents such as bills of exchange and promissory notes. Already notice has been given by the Minister of Finance of his intention to introduce legislation providing a uniform profits tax on the output of gold, diamonds, and base metals throughout the Union, which must shortly be followed by legislation introducing uniformity into the various laws which now prevail in the different provinces, prescribing the right of the State to a share in such portion of private land as may be discovered to be mineralised.

The Union Parliament will before long be called upon to fix a Customs tariff for goods imported into the Union. Since 1893 there have been Customs conventions between the different British South African States, formed for that purpose into a Customs Union. Under these conventions a uniform Customs tariff has prevailed throughout the Customs Union in respect of articles imported from outside, with a rebate on goods and articles the growth, produce, or manufacture of the United Kingdom. In most classes of goods this rebate at present amounts to 3 per cent. ad valorem. A similar rebate is given on goods and articles the growth, produce, or manufacture of any British Colony, Protectorate, or Possession, granting equivalent reciprocal privileges to the South African Colonies and territories, parties to the Customs convention. The advantage of this Customs arrangement between the different British South African States was that the duties on goods imported from outside the Customs Union into any one of them were paid at the ports, and there was no necessity, therefore, for erecting Customs houses on the boundaries separating the different States. Prior to the union of the self-governing colonies, there was no authority which could legislate for the whole of South Africa; the uniform tariff which has hitherto prevailed in its different colonies was settled from time to time at conferences of delegates from each of them, and submitted to their Parliaments for ratification. No amendment could be made in the tariff submitted; it had to be either accepted *in toto* or rejected. The different Parliaments concerned, anxious not to bring about fiscal confusion in South Africa by rejecting such a tariff, always accepted it, though strongly urging various objections to its different items.

The tariff settled at the last conference of delegates, held in 1906, though still in force, was objected to by each of the colonies on different grounds. A Conference of the Governments of the South African States was held in Pretoria in May, 1908, for the purpose of reconciling these differences as far as possible. The complete failure of the Conference in its object caused the first practical step to be taken towards the union of the South African Colonies by the passing of this resolution:—"In the opinion of this Conference, the best interests and permanent prosperity of South Africa can only be secured by an early union of the South African Colonies under the Crown of Great Britain."

It will be the duty now of the Union Parliament to settle a Customs tariff for goods imported into the Union from outside. The difficulties involved in such a settlement are great, and I will not attempt to make any forecast even of the main principles on which such a tariff will be based. There will undoubtedly be differences of opinion, among the members of the Union Parliament, on such questions as protective duties and rebates on British manufactured goods. A Commission has already been appointed by the Government to make inquiry into the industries of South Africa, and to recommend what support they should receive in the way of protection or bonuses. Addressing the South African Manufacturers' Congress, recently held in Cape Town, General Botha is reported to have said: "I can assure you that the fostering and developing of South African industries have the fullest sympathy of the Government, and I can assure you, further, that in cases where it can be proved that protection will lead to *bona fide* industries and not to unnecessary burdens on the country, your Association may depend upon support from the Government."

No doubt there are differences of opinion as to the advisability of continuing the existing Customs rebate on British manufactured goods, which involves a direct loss in Customs duties

to the Colonial revenue of over £500,000 a year. There are, however, other considerations of an Imperial character to which the Parliament of the Union will give due weight when dealing with this important question. For the year ending December 31st, 1910, the value of the total imports into the Union from oversea was about £34,000,000, of which 58 per cent. in value was imported from the United Kingdom, and 12 per cent. from British Colonies; 70 per cent., therefore, of the import trade of the Union, and about the same percentage of its export trade, is with the British Empire. South Africa is not a manufacturing country, and for that reason it offers greater opportunity to the British manufacturer than any other dominion of the Crown.

Some people talk as if the most serious danger to the prosperity of the Union of South Africa is the racial feeling between the English and Dutch people. I do not pretend to say that there is no such feeling to-day, but I have no hesitation in saying, that considering the conflicts of the past and the fact that a long and devastating war was only brought to a close ten years ago, with the loss to the burghers of the Transvaal and Orange Free State, and of the independence which they dearly loved, and for which they had gallantly fought, it is surprising to what extent that feeling has disappeared during the last three or four years. The conflicts between these races in ideals and aspirations were due, to a very large extent, to the fact that for political considerations, on which the people of South Africa were not consulted, that country became split up into parts not only under different administrations, but under different flags. No greater opportunity could have been given for the development of different systems and ideals. To-day, with all the different parts of South Africa, which were formerly self-governing, brought into a legislative union under the Crown, with equal political rights and equal rights of language symbolising absolute equality of the two races, with no shadow of pretence on the part of one race to be dominant over the other, there is surely no longer room nor justification for racial antagonism. The racial feeling will cure itself, and the less people talk and write about it, the sooner will that cure be effected.

The problem which overshadows all other problems in South Africa in difficulty and far-reaching effects is that which is generally expressed as the native question. I could take up the whole afternoon in discussing this problem from different points of view, but there is only time for me to point out some facts connected with it.

The European population within the Union of South Africa, the large majority of whom look upon South Africa as the permanent home for themselves and their children, does not exceed one and a quarter million, whilst the coloured population, largely scattered amongst the European, exceeds four million, consisting of different races in different stages of civilisation. About three and a half million are aboriginal natives, most of whom are still in a state of barbarism, but including a substantial and ever-increasing number of civilised men and women, among whom the demand for education is rapidly growing. Between the years 1894 and 1909 the number of coloured children at school has more than doubled itself, having increased from 80,000 to 170,000. In addition to the aboriginal natives, there are between 300,000 and 400,000 coloured persons with an infusion of white blood in their veins, living according to European methods, and whom the white man must always regard with sympathetic interest. A further addition to this mixture of races in South Africa are the Asiatics, numbering about 150,000, most of whom are British subjects, and whose presence in the country has given rise to questions of exceeding difficulty and delicacy, which are now receiving the earnest attention of the Government of the Union. The industrial fabric of South Africa is based on native labour, and there is not, therefore, the same demand for emigration from this country which exists in Canada and Australia. The number of skilled coloured workmen, of teachers, missionaries, and clerks, is daily increasing, causing a competition between them and Europeans which is one of the great difficulties of the situation. The problem with which South Africa is faced is what, in the interest of the country as a whole and in the interest of its different races, must be the relation between them socially, politically, and industrially. It presents itself in the framing of railway regulations, municipal bye-laws, in education, in the daily administrative work of the Government, and in the legislative work of Parliament. No one who has not lived in South Africa can appreciate the difficulties of this problem. Different views prevail as to the manner in which it should be solved, but no man living to-day can forecast its ultimate solution. A sound native policy must be slowly and naturally developed, and in that development

the only course, in my humble opinion, is to adhere to the good sound principles of justice and freedom and toleration. The action of the Union Government in the release of Dinizulu and of the other native chiefs banished to St. Helena under sentence for rebellion by courts-martial, as well as the repeal of Natal compulsory native labour law, are encouraging signs of the Government's attitude towards this problem.

The dual language makes the subject of elementary education an exceedingly difficult and delicate one. Unfortunately, the Constitution gives the control of it to the Provincial Administrations instead of to the Union Parliament. While the Education Acts of the Cape of Good Hope, Natal, and the Transvaal, on the whole, appear to satisfy both races, the English-speaking section of the European population of the Orange Free State have denounced the provisions of the Education Act of that province as unfair to the English language. I refrain from expressing any opinion on a matter on which, to a very large extent, the first election of members for the House of Assembly of the Union Parliament was fought. Early during the present session of that Parliament a resolution was brought forward condemning the Orange Free State Act as a violation of the provisions of the Constitution relating to equal language rights and opportunities. By an amendment to the resolution, moved by the Prime Minister and accepted by both parties, all the Education Acts of the provinces have been referred to a Select Committee of the House of Assembly, to report in what respects they should be amended so as to comply with the principles laid down in the Constitution. The Parliament of the Union itself has no jurisdiction to make any amendments which may be necessary for that purpose, but it is sincerely to be hoped that the Select Committee will bring forward such moderate and reasonable recommendations that each of the Provincial Councils will loyally accept them, and, if necessary, amend its Education Acts in such a way as to give no cause to either race to complain of injustice to its own language. Separate schools for English and Dutch children would, in my opinion, be a disaster of far-reaching effect. The fact that the children of both races now attend the same schools and grow up together will make the next generation of men and women free from racial feeling.

I have only time now to refer to one other problem, which must be dealt with by the Government and Parliament of the Union within the very near future, and that is the question of defence. The supremacy of the British Navy is essential to the safety of South Africa and to the protection of its oversea trade, situated as it is on one of the world's highways, with its long coast-line, with its territory marching on one side with that of the most powerful military Power in Europe, and on the other side with Portuguese territory; with an oversea trade of the value of nearly £100,000,000, the most important articles of export and import being included among those which, under the Declaration of London, are styled conditional contraband, liable to capture in neutral bottoms. More and more South Africans recognise their responsibility in helping to maintain the strength of the Navy. Before the Union the Colonies of the Cape of Good Hope and Natal contributed together an annual sum of £85,000 towards this object. That amount, which is being continued by the Union Government, will, no doubt, be considered as wholly inadequate. In criticising it, due weight ought to be given to the fact that the Union of South Africa practically contributes, in the shape of Customs rebates, over £500,000 a year to the support of British trade in South Africa. From the public speeches of responsible statesmen, there seems to be no prospect that the policy of small navies will be adopted, and South Africa's contribution to the naval defence of the Empire will probably take the form of an annual vote of money to the British Admiralty, in the amount of which due regard will be given to such expenditure as the Government of the Union may incur, with the approval of the Admiralty, in connection with local coast defences.

The Union of South Africa fully recognises its entire responsibility for its own local defence. It differs from the other self-governing dominions in having a serious native problem to deal with. When the native protectorates are brought within the Union, the Government will be responsible for the control of over five million natives, and it will be necessary to maintain local forces of sufficient strength to keep order therein. Excluding the police, the total strength of the militia and volunteer forces maintained by the four colonies which now form the Union is about 12,400, of which only about 670 are maintained on a permanent basis. The total strength of the mounted police is about 2,500, "a magnificent and well-mounted permanent force, receiving an amount of military training which varies in the different provinces. By force of circumstances, the police are necessarily

distributed in small detachments over wide areas of country, and it is impossible to collect them for any form of training to work together in large bodies; without such training they cannot be looked upon as a military force. They can, however, all ride and shoot, and are good horsemen."

In addition to the 12,400 local forces before-mentioned, there are also 11,000 members of rifle clubs, and about the same number of cadets under training, and an organised reserve volunteer force in the Transvaal of 1,000 men.

The forces at present available, excluding the British troops, which sooner or later will be removed, are quite inadequate to provide against the various requirements in connection with the defence of the Union. Though no scheme has yet been submitted to Parliament, the Prime Minister and Minister of Defence have both publicly announced the determination of the Government to raise a sufficient force to enable them to undertake responsibility for local defence, and have given some slight indication of their views as to the character of such a force. In a speech made just before the general elections, Mr. Smuts, the Minister of Defence, said: "Some people think we are going to have a great standing army. The people in this country do not want that. What they do want is a citizen army and a small striking force. In the second place, we shall require a permanent corps of instructors to train the citizens in their military duties." Universal service, already theoretically in force in Natal and the Cape of Good Hope, under the Defence Acts of those colonies, is foreshadowed in the political programme of the Nationalist or Government Party as follows:—"The establishment for South Africa, as a part of the Empire, of an adequate system of national defence, which will recognise the obligation of the citizen to take part in the defence of his country." In this connection it is important to note that the Minister of Defence has clearly explained in recent speeches that what is intended is some form of universal training. The system foreshadowed by him is, first, the encouragement of cadet corps in all schools, and, secondly, universal training during a certain period every year between the ages of eighteen and twenty-four.

In formulating a scheme for the submission to Parliament, the Government will have the advantage of the advice of Lord Methuen, who is taking the greatest interest in this question, and no doubt full consideration in any such scheme will be given to the plea put before the Imperial Defence Conference by the Army Council of similarity of organisation in all the defence forces of the Empire, so as to facilitate mutual support in times of emergency.

I am afraid this paper has extended to a greater length than is usual on these occasions. There are many other South African questions to which I should like to have referred, but time will not allow of it. I have been obliged, as it is, to give merely a sketch of a few problems which I thought might be interesting.

DISCUSSION.

The CHAIRMAN stated that he had immediately to return to his work in the House of Commons, but he could not do so without expressing, on behalf of the audience and himself, their gratitude for, and admiration of, the illuminating paper which the author had read. Lord Blyth had kindly consented to take the chair for the remainder of the meeting.

[The chair was then vacated by Mr. Harcourt, and taken by Lord Blyth.]

The Right Hon. Sir WALTER HELY HUTCHINSON, G.C.M.G., thought it would have been impossible for the Royal Society of Arts to have found a better guide, philosopher, and friend in their inquiries into the resources and problems of the Union of South Africa than his old friend, Sir Richard Solomon. Sir Richard was born and bred in the country; he was educated in South Africa until the years of adolescence, when he paid a visit to England, and at Cambridge succeeded in taking very high honours. He returned to South Africa, where he had a practical experience during many busy and strenuous years, and became a shining light in the learned profession which he adorned. He was the trusted legal adviser of one of the greatest corporations in South Africa during many years. After an excursion of some two or three years on the stormy sea of Cape politics, from which he emerged safe and sound, he became the not less trusted adviser of the Military Administrator of Pretoria after the war, and subsequently of the Crown Colony Government; he took his share in laying the foundation of the administration of the Transvaal, which now formed a part of the Union of South Africa; and, finally, he was now the chosen representative in England of the free Union Government of South Africa. He did not think it would have been possible to find a man better qualified to give an address on the resources and problems of the Union. The author had suffered under limitations of time and also of responsibility. No one knew better than he (the speaker) how difficult it was to draw up an illuminating address upon a subject which

interested not only the people whom one was addressing, but people at the other end of the world, who would always be ready to find fault with any slips, or expressions of opinion of which they did not approve. But Sir Richard had presented a clear and concise statement of the case; he had marshalled his facts with ability, and presented them in such a manner that they were easily understood; and he was sure the members of the Society were grateful to him for the pains he had taken, and for the success he had attained. It was, indeed, a remarkable story of progress, of development, and it contained great promise for the future. He had lived long enough in South Africa to have heard similar stories of progress and development. It had become almost proverbial, that in South Africa there was always "either a feast or a famine"—a period of boom, followed by a slump, and so on in alternation. He hoped that the story of promise which the author had narrated did not point to any extraordinary boom, but rather to peaceful advancement in the path of progress, which would gradually increase until South Africa became, as all who loved her hoped she would become, one of the brightest stars in the galaxy of Empire. There was only one statement in the paper that he desired to criticise — the statement that South Africa was not a manufacturing community. South Africa certainly was not a manufacturing country at present, but it did possess some manufactures. For instance, there was the manufacture of dynamite, of which article the Somerset West factory last year turned out no less than 370,000 cases; and there was also a large factory of dynamite near Durban, and another in the Transvaal. At the Durban factory the manufacture of glycerine from the whales which were caught on the coast of Natal had been commenced, and he had also heard that the enterprising Mr. Lever was laying down a great soap factory at Durban. He did not know whether beer could be called a manufacture, but a certain quantity of beer was produced in the country, and also wine, tea, sugar, matches, candles, and certain other things; but he admitted they were mostly produced in a small way, and always under protection. Nevertheless, it pointed to what might happen in the future; and when it was borne in mind that in South Africa there were millions of tons of iron ore lying close to the coal and to the limestone, only an adequate market and adequate labour and capital were required to start a manufacture of steel in South Africa which would take its place in the world. The whole thing, however, turned on the question of labour. That brought him to dwell upon the truth of what the author had said as to the vital importance to South Africa of the native question, which overshadowed all other questions in the country, whether on its economic, its political, or its social side. The author had mentioned that 200,000 natives were now working on the Rand; that a few years ago only 2,600 natives from Cape Colony were working at the mines, and now there were 80,000. That was true, and it was due to a certain extent to the improvement of methods of recruiting, in the accommodation for, and treatment of, the natives. It was also due to the fact that, just at the time when that large increase in native labour was required, there was a most terrible depression in South Africa. Natives were thrown out of employment at Kimberley by the thousand; the Governments ceased making railways; the ports did not do half the business they had done before, and all that helped to bring the natives to the Rand. Although there were 200,000 natives on the Rand at the present time, he was informed on good authority that 70,000 more natives were now required there. As a matter of fact, there were complaints of shortage of labour from all over the country. The Rand was not the only employer of labour. A great expansion was taking place in Rhodesia, and a further expansion must be expected now that the railway had reached the Congo State. The tea and sugar industries, and the coal industry, would now require more native labour, because of the stoppage of indentured coolie immigration. The demands for labour came from all quarters; and if, as the author anticipated, the agricultural interest in South Africa became, as he (the speaker) hoped it would become, one of the principal agricultural industries in the world, an enormous amount of labour would be necessary. In the matter of labour, South Africa might be said to suffer from a kind of auto-intoxication, of which the doctors spoke so much. A man might live well and grow fatter and stronger, but suddenly he felt ill and had to send for the doctor, who told him he was suffering from self-poisoning. In the same way, in South Africa, in times of depression labour became plentiful; the gold mines went ahead; the country progressed; people began to be better off; the Governments were richer and began to make railways; there was more trade in the ports; the farmers required more labour, and so the period of prosperity which was caused by the quantity of labour brought about scarcity of labour and checked prosperity. The economic side of the native question—the labour question—was one of the most important questions that would face the Union Government. He associated himself with all the author said about the relations between the Dutch and the British in South Africa. He noticed a telegram that day in one of the morning papers to the effect that an agreement had not been arrived at by a committee appointed to discuss the teaching of Dutch in the schools in South Africa, and that this might lead to the resignation of General Botha. He did not know whether it would lead to the resignation of General Botha—he did not believe it would; but whether it did or did not, the teaching of Dutch in the schools was relatively a minor question which would settle itself, and people in this country need not bother their heads about it. The people of South Africa had got to arrive at a settlement which would meet with the

general acquiescence of the whole of the people, and that settlement they would arrive at sooner or later. On that subject he felt as happy as possible, because he believed the two races would work together for the good of South Africa. They would derive from each other their best qualities, and in the end would evolve a type of which the nation as a whole might be proud.

Mr. P. J. HANNON said that the serious question of settling the preference to be given to British goods in the South African market would soon be brought up for discussion, and he hoped the author would use his influence to get the present preference on British goods continued, as it was a matter of great importance to the manufacturers of this country. The effect of that preference in favour of British produce enabled British manufacturers to get their goods into the South African market, and at the same time it helped labour in this country by providing employment. He hoped when the question came to be settled that the present preference would be retained in favour of the producers of this country.

The DUKE OF ARGYLL, K.T., in proposing a hearty vote of thanks to the author for his illuminating paper, said he was sure it had been an immense pleasure to the audience to hear a paper from a past-master in South African affairs, and he trusted it was not the last paper the Royal Society of Arts would have the benefit of hearing from the author on the subject. Sir Richard was thoroughly representative of the great communities in the union which had been effected, and it was very necessary that the people of this country should have instruction on South African affairs from instructors who really knew what they were talking about. Unfortunately, he had no personal acquaintance with South Africa, but he had been connected for a long time with a company which had to do with East Africa, and he was one of those who helped to push the British flag into Uganda. No one at the present time regretted that that had been done, although at the commencement of the operation there might have been a little difference of opinion on the subject. He spoke with greater freedom on that point since the Secretary of State for the Colonies had left the meeting. He must not, however, hark back upon that old controversy, except to say that he did not think anybody belonging to the present generation regretted that the British flag was now more or less dominant from the Nile to the Cape.

Sir DAVID GILL, K.C.B., F.R.S., in seconding the vote of thanks, said he could not plead, like his Grace, that he knew nothing of South Africa, for he had spent twenty-seven years of his life in that country. He could not, however, give any information as to what South Africa was like now, owing to the great and mighty political revolution that had taken place since he left there—a revolution which he trusted had been of the most beneficial kind for the future of that country and for the Empire. He could confirm, so far as his knowledge went, the accuracy of all the statements made by the author, and he was delighted to notice the hopeful and confident spirit which had characterised his remarks.

The CHAIRMAN (Lord Blyth), before putting the resolution to the meeting, said that many useful papers had been delivered in the hall of the Society, but he could not conceive of any paper being more useful and instructive to the whole of the people of the British Empire than the paper Sir Richard had delivered. It was interesting, not only to the people of the United Kingdom, but also to the people of the Overseas Dominions, and if publicity was given to it, he believed great good would result.

The resolution of thanks was then carried, and, Sir RICHARD SOLOMON having briefly acknowledged the compliment, the meeting terminated.

THIRTEENTH ORDINARY MEETING.

Wednesday, March 8th, 1911; Sir SHIRLEY FORSTER MURPHY, F.R.C.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Barnes, Carl L., M.D., LL.B., 1977, Ogden-avenue, Chicago, Illinois, U.S.A.

Carroll, Alexander Ernest, Assoc.M.Inst.C.E., 7, Appion-way, Dublin, Ireland.

Crump, Colonel Malcolm Hart, Room 2, Elks Building, Bowling Green, Kentucky, U.S.A.

Darling, Charles Robert, Beechurst, 186, Eglinton-road, Plumstead, Kent.

Field, George Moyle Robert, M.Inst.C.E., 203, Coleherne-court, South Kensington, S.W.

Goldschmidt, Dr. Hans, 98, Bismarckstrasse, Essen-on-the-Ruhr, Germany.

Mason, Frank, M.Inst.M., 42, Birkendale-road, Upperthorpe, Sheffield.

Pitkin, Rev. John, Shapwick-cum-Ashcott, near Bridgwater, Somerset.

Wale, Charles, 8, Great George-street, Westminster, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Brichett, Dr. J. G., Cardwell, Missouri, U.S.A.

Bruck, Walter W., 64, High Holborn, W.C.

Converse, Edmund Cogswell, Conyers Manor, Greenwich, Connecticut, U.S.A., and 72, Broad-street, New York City, U.S.A.

Down, St. Vincent Bowen, Winchester House, Singapore, Straits Settlements.

Gladwell, Arthur, Brynmaur, Gerrard's Cross, Bucks.

Harvey, Ernest William, F.C.S., The British Empire Club, 12, St. James's-square, S.W.

Hastings, Percy, The Cottage, Wimbledon-common, S.W.

Moitry, Manmatha Nath, Serampore, Hoogli District, Bengal, India.

Williams, Stacy B., Brockweir, Urmston, near Manchester.

The CHAIRMAN, in introducing the reader of the paper, said the subject of plague was one that could not receive too much attention. The history of the past showed what it did years ago in this country, particularly in London. It had recently manifested its old virulence in other countries, and there had been reason for thinking seriously of it in the eastern counties of England. There was an excellent Government department dealing with the matter, and there was also a sanitary service, which did not exist in the old days; but it was of the greatest importance at the present time that the public should know what plague was and how it was caused. The author had a very ripe experience of the disease, having been in charge of the plague wards in the plague hospital of Hong-Kong during the outbreak of 1894; and he was intimately associated with the discovery of the plague bacillus at that time. He had had under his personal observation for a number of years, on behalf of the London County Council, every person who had in any way been suspected of suffering from plague, and it was due to his assistance that it was possible to say there had been no plague in the London community.

The paper read was—

PLAGUE AND ITS SPREAD.

By JAMES CANTLIE, M.A., M.B., C.M., D.P.H.

The prevalence of plague in the world in epidemic form since 1894 to the present moment—a period of sixteen years—is a matter of supreme interest and importance to the people of every nation. The question naturally arises at the moment: Has the virulence of the malady spent itself, and may we look forward to an abatement of the pandemic, and a hope that it may speedily disappear altogether? The history of previous epidemics does not engender a hopeful answer that it may do so; indeed, the opposite obtains, for all previous outbreaks indicate the long continuance of plague amongst every community in which it has gained a serious hold. Plague is also a slow travelling disease, for it took nine months to travel from the City of London to Soho in the seventeenth century. It is not a question of a prevalence for a few weeks or months or even years, but a continuance for several decades in any populous district where it has found a footing. In London, when plague last visited us in the seventeenth century, although the mortality was high for only a comparatively short time, local outbreaks occurred for a long period, and sporadic cases until the beginning of the eighteenth century. Judging even by the behaviour of the present epidemic, plague has lasted now for seventeen years in Southern China, and for fifteen years in India. Speedy disappearance of the disease from regions severely attacked is, therefore, not to be calculated upon—in fact, its long continuance is rather to be expected. It is this characteristic of plague which causes the disease to be dreaded as it is, for it is the only malady which prevails in epidemic form for a number of years in any given country.

The endemic home of plague amongst human beings is a matter of doubt. So far it is believed that plague is always present in the Indian Provinces of Kumaon and Ghurwal, on the southern slope of the Himalayas; but whether this is the only home of the disease, or whether there is, in addition, another in Mongolia, and yet another in East Africa, is not known. It may be that in no part of the earth is plague endemic amongst men, but that the disease is kept alive only amongst certain animals, and now and again in the history of the world does it attack man. There is much to be said for this opinion. Certain animals, especially of the rodent class, seem to be liable to plague in an epidemic form, but whether it is endemic amongst these animals is not known. That plague is endemic amongst rats is not known. That it occurs in epidemic form is abundantly proved, but whether it is the rat that keeps the bacillus alive from one century to another seems uncertain, and it is unlikely from the very fact that it is so virulent amongst them at times. I would rather regard, from the evidence to hand, plague as being as alien a disease amongst rats as amongst men. If I were to single out any one animal on which one might saddle endemic plague, I would fix upon the marmot (the *Arctomys bobac*) in preference to all others. This marmot inhabits the mountainous backbone of Asia from Mongolia to the Caucasus. It is akin to the squirrel in appearance, and this group of animals seems specially susceptible, for we know that in Western North America the ground squirrel is readily affected in the wild state with the plague bacillus.

It is in the very region the marmot inhabits that we hear of plague from time to time, even when there is no pandemic. Kumaon and Ghurwal come into this geographical category, and at the extreme eastern portion of the

mountain range plague has been known to exist in endemic form since 1878 amongst men when the marmot is known to harbour the disease. This question, however, cannot be settled until more information is obtainable; and the opening up of Asia to the north of the Himalayas by railway will serve to help us to solve the problem. Plague manifests its presence in man more frequently in the form of bubonic plague than in any other form. In Biblical times even the bubo or emerod, as it is spoken of in Leviticus and I. Samuel, was the prominent evidence of the presence of the disease. Surgically a bubo means an enlargement or swelling occurring in a gland anywhere in the body, due to some irritation or inflammation in its neighbourhood. We are familiar with such an occurrence when, should the hand be poisoned, we get a swelling of the glands in the armpit, or, when the skin of the foot is irritated, we get a swelling in the groin. In plague there are three situations in which buboes may be felt. Most frequently it is the groin glands that enlarge, but the glands of the armpit and the neck may be the seat of the swelling. On the other hand, the glands along the front of the spine from the chest to the abdomen may be swollen, but as they are deep-seated, they cannot be made out except by post-mortem examination.

The bubo, however, is not the first indication of the disease; in fact, it is rather a late manifestation, for it may not be until the third day or later that it shows. Like other infections, plague begins with feverishness, headache, backache, a feeling of chilliness, or even a rigor; there is loss of appetite, a foul tongue, usually black in centre, and congested throat; vomi ing is frequent, and diarrhœa or constipation obtains; mental aberration is an early manifestation, and may continue throughout the illness. At times it takes the form of active delirium, or an apathetic type of derangement prevails, the patient being placid and unimpressionless, neither hearing nor seeing properly. The delirium may take the form of apparent suicidal intent, as many get out of bed and make for the window or verandah. There would not appear to be any set purpose in this action, and a fall from the verandah on such occasions is due to accident merely. Around the bubo, or independently, blood is effused beneath the skin, sometimes in large patches of a foot or more square, sometimes in several or many smaller areas in different parts of the body. The appearance of buboes may be early or fairly late in the disease. The bubo or buboes, as there may be several in a group, develop quickly, and in a few hours may reach large dimensions, varying in size from a hazel nut to a Bath bun. There is some local pain over the bubo, and the skin over it becomes red or dusky, and if the patient lives long enough, indications of pus having formed occur about the fifth day, and by the eighth day the skin over the bubo sloughs, a quantity of pus escapes, and a large ragged ulcerating surface is left. As a rule, if the patient lives over the fifth day, recovery may be expected, but the third and fifth days of the illness are the most dangerous. If the eighth day is survived, the hope of recovery is good, the chief danger then being failure of the heart through sudden movement or getting out of bed, walking across the floor, and leaning over the verandah, or staircase railing.

Along with the bubonic form of plague, a septicæmia or acute blood poisoning form of the disease occurs. The signs and symptoms are more acute, the temperature is higher and more sustained, the pulse quicker, buboes do not occur; it may be because the patient dies before there is time for development, and the delirium is more active and uncontrollable. The patient usually dies of acute pulmonary congestion or pneumonia.

The pneumonic form of plague we have heard especially about in the epidemic which is now raging in North China. It is an acute form of the disease, which attacks the lungs so extensively that death comes in two or three days. It is highly infectious, runs rapidly through a household, and occurs with such rapidity and virulence that there is no time even to bury the dead. The plague in North China recalls the accounts given of plague in former epidemics in Europe, and the Black Death, with all its horrors, is abroad in the world. We begin to understand that there may be stages in the development of plague epidemics, reaching from a low to a high degree of virulence, and from a meagre to an extremely dangerous state of infectivity.

Pestis minor.—In attempting to gauge the epidemiology of plague, it may be well to deal with the matter from a historic point of view. In 1893—that is, the year before plague became epidemic in South China—a large number of cases of "buboes," in the groin especially, prevailed throughout the Far East from Singapore to Hong-Kong, and possibly elsewhere. The writer brought up the

matter for discussion at the British Medical Association Branch in Hong-Kong, and several letters were received about the same time from medical men in Singapore and from French doctors in Saigon, asking if in Hong-Kong we had experience of these "buboes," as they had seen so large a number that it might be termed an epidemic.

I termed this outbreak as a "bubo d'emblée," and stated that I had treated thirty-eight cases in thirty-two months.

Going still further back to 1891, I reported to the Medical Society of Hong-Kong twenty-three cases of glandular enlargement met with amongst children in Hong-Kong. There was feverishness, but no throat affection, nor was the parotid gland enlarged as in mumps. The condition puzzled us, and for convenience sake we (the doctors) styled it mumps, although we knew otherwise. This is interesting, for in Astrakhan, in 1877, when plague was in the district, the doctors there also spoke of "a peculiar form of mumps" prevailing there. Again, seeing that glands, except strumous neck glands, are seldom excised, I examined the records of the Government Civil Hospital in Hong-Kong in connection with the excision of glands, and I found the following:—In 1891, 19 groin buboes were excised or scraped; cervical glands, 1. In 1892, I had not the record. In 1893, 27 buboes were excised. In 1894, 12 buboes were excised and scraped. I have searched many hospital reports for records of excision of buboes, and nowhere in the world have I found buboes operated on to the extent which is recorded in Hong-Kong between 1891 and 1894. In the British Navy also, on the China Coast and on the Zanzibar Coast, buboes in sailors were reported and termed climatic bubo. In all these reports, plague, typical plague, was present, or plague subsequently occurred, and I am convinced that the bubo d'emblée, the "peculiar form of mumps," and "climatic buboes" are all cases of *pestis minor*, a disease having a special type, not a mild variety of true plague, but a variety due to a type of bacillus allied to the true plague bacillus, but with less and what may almost be termed a specific variety of the bacillus.

I had a case of climatic bubo in London, in a doctor just home from the Mysore goldfields, where he was on plague duty for a considerable time. Professor Hewlett found in the discharges a bacillus resembling a plague bacillus, but *not conforming with all the tests necessary to stamp the disease* as one due to the presence of the typical plague bacillus. The *non*-conformity is, perhaps, the most interesting point of all from what we now know of plague. It is possible that we are dealing with varieties of plague bacilli which bear distinct relation to the type of the disease which prevails at any given time or place. That "climatic buboes" are neither more nor less than plague due to a special variety of the bacillus (usually termed a pseudo-bacillus) which is met with in pronounced types of the disease, there can be no doubt, and the writer has styled the condition *pestis minor*. It will be seen that by this is not meant a mild clinical variety of virulent bubonic plague, but a disease due to a special strain of the plague bacillus, which runs a definite course and only gives rise to its like (for a time) in other people. That *pestis minor* runs also concurrently with true plague was well illustrated during the outbreak on the Volga in 1877. At Astrakhan true plague prevailed, and many deaths occurred, but in a town 150 miles higher up the Volga the people suffered from an outbreak of buboes which amounted to an epidemic, but no deaths resulted; they, in fact, had the specific type of mild infection—*pestis minor*.

I would classify the possible stages of plague infection of a country as those of:—

(1) *Pestis minor*.

(2) Bubonic plague.

(3) Pneumonic plague.

That these are related the one to the other would seem incontestable; that each possesses a special variety or type of virulence due to peculiar characters of its bacillus, and transmitted in different ways in each type, would also seem true. The rat-flea infection plays, no doubt, a part in this scheme, but, as Dr. Hossack, of Calcutta, remarks, it is but a link in a chain of some length—a chain, we would add, in which other animals and man play a part.

I have devoted considerable space to this part of the question, because it may be of importance in estimating the approach of plague in any country, and it would be well to keep this point in view in our hospitals in this country, and to watch if cases of non-venereal buboes are becoming more prevalent. In this way we might hope to gauge the proximity of true plague in its virulent forms.

It may be interesting and instructive to refer to the history of the plague in Mongolia, in connection with the Manchurian outbreak, with which it is no doubt directly connected.

In the district of Aksha, in the Transbaikal

Province of Siberia, plague has been known to exist since 1888. Aksha is in longitude 115° east, and latitude 50° north, and the principal centre of plague is round Tzagan-olui, a place close on the Russo-Mongolian frontier. The disease is known in that district as *tchuma*, the Russian term for plague. Here the tarbagan (*A. bobac*) is regarded as the cause of the disease in man. The tarbagan is much sought after by the Cossacks and Buriats who inhabit the district, for the sake of the fat which accumulates chiefly in the abdomen towards the autumn, and just before the animal retires into its hibernating quarters in September.

The tarbagan is in some years attacked by an epizoötic with the following symptoms: the animal becomes languid and ceases to bark; its gait is unsteady, and under one shoulder there sometimes appears a reddish, tense swelling; if far from its hole, the animal fails to find it, and if it reaches its hole, the other healthy animals refuse it admittance, when it falls a prey to wolves, who have a great liking for marmot, whether healthy or diseased. The wolves do not contract the disease from eating the marmot, and this scavenging by the wolves is considered the chief reason why men escape from the disease so frequently as they do. Should, however, people handle a marmot dead of the disease, sickness is almost sure to follow, and death, as a rule, occurs in a few days. This disease, which is endemic in the district referred to, is now recognised locally as identical with plague, but its spread is confined to the family of the person first attacked. It would seem probable that the fleas of this animal communicate the disease to the members of the household, and that only those bitten by them are attacked by the disease.

A different state of affairs, however, exists in a district in Eastern Mongolia, some 480 miles further south. In this district plague was known to exist in 1888, and every year since it has recurred regularly, now mild, now more severe. Although tarbagan are numerous in the district, no observers nor the people themselves attribute the disease to infection from marmots, rats, or domestic animals, as none of these have been found diseased. These observations are interesting, and the behaviour of the disease in the two localities is equally so. In the Siberian centre the disease is occasional, coming only when the marmot is affected, and seldom spreading beyond the house where a diseased marmot has been handled. In Mongolia the animals are not known to be infected, the disease occurs annually in the summer, and it spreads in an epidemic form amongst the people over a considerable area. Here we have two forms of spread, one occasional and attacking members of one household, the other regularly recurring, and affecting the neighbourhood in an epidemic form. The former is from infected animals, the latter from infected people. In the Mongolian outbreaks pneumonic forms occur in about one-third of the persons attacked. It is interesting to note that in the Mongolian centre a number of Manchurians have settled, and between the two places, no doubt, people pass backwards and forwards from time to time, and since the railway opened intercommunication has become more free. The disease which appeared in Manchuria in 1910 is more of the nature of that which prevails in the Mongolian centre, but the pneumonic form prevails. Here we would seem to have interesting material for consideration. One centre is Siberia, where the disease reaches man from an animal, the marmot, and appears in endemic form; a second centre is Mongolia, where the disease is partly bubonic and partly pneumonic; a third centre is Manchuria, where the pneumonic type prevails. This would serve to support the belief that the plague bacillus passes through stages of development in type: first, the variety that is brought about by the bite of fleas of an animal suffering from the disease, but not going further; second, the type which becomes epidemic by passing from man to man, probably by fleas carrying infection from one individual to another; third, the type that passes from man to man without the intervention of a carrier or by insects as well.

The lesson to be learned from this is that there are three stages in this disease. *Pestis minor*, carried only by insects from diseased animals, is always local—a household outbreak, in fact—in which a pseudo-plague bacillus is found in man. Bubonic plague is carried from man to man by insects. Pneumonic plague passes from man to man without the intervention of insects. The virulence of each variety gathers in intensity. Time is required for one type to change to another more virulent, each variety propagates its like until, by prolonged cultivation in the blood and tissues of a particular animal, or in man, it changes its type and becomes specific for that animal. As the tuberculosis of animals may in time and in suitable soil change in type, so that it develops in man, and then is directly transmitted from man to man, so is plague in time altered in

type, so that it no longer requires an animal host, but in times of epidemic passes from man to man, and becomes wholly a disease of human beings.

The stages would appear thus to be:—

(1) Disease in animals.

(2) *Pestis minor*, conveyed by infected insects.

(3) Bubonic plague, sporadic cases, carried from animals to man by insects.

(4) Epidemic bubonic plague, carried from man to man by insects.

(5) Pneumonic plague, passing from man to man directly, or conveyed by insects.

It would seem, therefore, that severe as bubonic plague has been in China and India, yet a worse form may develop, for pneumonic plague is the culmination of this chain of virulence, and China and India may have been but the fostering beds in the development of the bacillus which has now attained its highest development in Manchuria, and may pass over the world, as it has frequently done before, in the form of the Black Death. At present, science offers no means of preventing such a calamity, except it be a preventitive such as Haffkine's prophylactic serum, which would seem to have done good service in India, where bubonic plague has chiefly prevailed.

That some such scheme of development appears probable, all evidence indicates. We had first in the Indo-China and Chinese coast climatic buboes, or *pestis minor*, then bubonic plague in South China, which, transmitted to India, continued its type there; then during the continuance of bubonic plague in China and India, the appearance of at first a few and then a number of cases of pneumonic type; and finally the appearance and continuance of a primary pneumonic plague in North China.

Infection by rat fleas is sufficient to explain sporadic cases of bubonic plague, and plague endemicity, but it is wholly inadequate to explain an epidemic of bubonic plague which can only occur by infection from man to man, possibly by insect carriers.

An important point to be observed in the epidemiology of plague is that animals, chiefly rodents, the rat in many places, the marmot in North China, the squirrel in the United States, &c., may suffer from plague for years without infecting mankind, except in a sporadic way. Then suddenly an outbreak occurs which prevails in an epidemic form. In Northern China this has been proved to be the case, and in any country where rodents are infected, the same sequence may be anticipated. Rats have been found to be infected in Britain, in Glasgow, in the Port of London, and in Suffolk; also in Germany, in Hamburg, and elsewhere; squirrels are known to be infected in the United States, more especially on the Pacific slope. In these countries small outbreaks of a sporadic nature have occurred from time to time. The outlook, reasoning from experience, is not hopeful, for the peoples of these countries are dwelling in places in which rodents are infected, and at any moment the disease may appear in an epidemic form in man.

DISCUSSION.

Professor W. J. R. SIMPSON, in opening the discussion, said the maps and facts the author had placed before his audience showed that the plague had spread in a very short time over a considerable part of the world. About fifteen years ago the disease was considered to be extinct, except in certain very remote parts of which mention had been made, the reason of its abolition being put down to civilisation and the progress of the nineteenth century. It had recently reappeared, however, with renewed strength, and it had come to stay. He agreed with the author that plague was a formidable disease, not only to Asiatics but also to Europeans. Thirteen years ago Mr. Birdwood, after his return from Poona, read a very interesting paper before the Society on "The Plague in Bombay." Having recently arrived from India, where he had been at work in Bombay and Poona, he (Professor Simpson) ventured at that meeting to differ from the views taken in regard to plague by some of the speakers. He viewed the disease as an expanding one, and emphasised the fact that although the operations for its extermination seemed to be successful, the organisation at that time was entirely inadequate and unscientific, and that it was impossible by such means to prevent the spread of plague. Some 30,000 deaths had at that time occurred from plague in India, but since that time over 7,000,000 deaths had taken place. Only last week, and for many weeks previous to it, there had been 20,000 deaths from plague in India. The same was the case in China. The differentiation the author had made between the two forms of disease arising from the tarbagan and also the pneumonic form in China was very interesting. Whether the tarbagan produced the pneumonic form he was not prepared to say, because pneumonic plague could be obtained without the tarbagan. It occurred in West Africa, where bubonic plague gradually developed into a virulent pneumonic type. In the West African epidemic the whole of the cases after a short time were pneumonic, and nearly every patient died. Plague was an expanding disease, and once it got into a country it was difficult to get it out. Not a single word would have been heard about the plague in Northern China if it had not occurred on the route of the

Trans-Siberian Railway. Telegrams were published in the daily papers saying that the plague had subsided. It had undoubtedly subsided in those particular localities, and nothing more would be heard about it until that form of plague was seen a good deal further west. China was a large country, and whatever happened there was not known to the European unless it occurred on the railway or at some missionary station. The danger of pneumonic plague was its infectious nature; it was carried from person to person like influenza. Many cases were not recognised, and they constituted the great danger. So far as immunity was concerned, he believed Europeans were no better off than they had been hitherto. He did not believe Europeans were immune from the disease once it got among them, and it was only by intelligent organisation that they would be able to fight it. He believed that it was absolutely essential, as the author had stated, that even in England there should be a proper organisation against the rat plague, the dangers of which the author had so interestingly brought to their notice.

Dr. L. W. SAMBON said the author was the first to state that the disease which appeared in Hong-Kong was the plague, but nobody believed him at the time. While doing some operative work, Dr. Cantlie wounded himself, and as the wound became poisoned, he left Hong-Kong and travelled for a time. On landing in Japan he heard that plague had broken out in China, and, together with his wife, Dr. Cantlie at once went back to Hong-Kong. On arriving at Hong-Kong he met a Japanese doctor, Dr. Kitasato, who had begun to investigate the disease, and who thought he had discovered its cause. At the same time a French naval doctor had just landed—Dr. Yersin—who was altogether unprovided with the necessary apparatus for scientific investigation. Dr. Cantlie at once put his laboratory at Yersin's disposal, and Mrs. Cantlie prepared culture media; and by means of the help thus rendered Yersin discovered the organism which caused plague. The epidemic of plague which overran the world in the fourteenth century began exactly in the same way as the present epidemic. It came down from the plateau where the marmot lived towards China; it then spread to India and various parts of Asia, and finally appeared in the Crimea, taking exactly the same route that the disease was taking at the present day. But at the present day means of communication both by land and sea had multiplied so much that the danger was far greater. The present pandemic of plague was the widest that had ever been known in history, because for the first time Australia, South Africa, and America had been attacked. The one point in favour of the present situation was that precise knowledge was available of the cause and the mode of the spread of plague. The ancients knew that the rat was the great carrier of the disease, and they also knew that vermin of smaller kinds, blood-sucking insects and flies, were capable of conveying the plague. All the measures taken by the ancients were directed against the rat, and the insects that carried it from rat to man and from man to man. In Aesculapius, the God of Medicine, with his staff with a snake entwined, there was an interesting record of one of the most glorious victories of man over a fearful scourge, namely plague. That snake was symbolical of the introduction into Europe, and the use in many parts of the East, of the snake to destroy the rats that carried the plague. The pine-cone, another symbol that was usually placed by the side of the Greek God of Medicine, referred to the incense yielded by the pine-cone. This served to disinfect the houses and to destroy the insects which became dangerous in time of plague. Unfortunately the knowledge of the ancients with regard to the etiology of plague was forgotten during the Middle Ages. Dogs, cats, rabbits, pigeons, and all animals which might, by breeding large numbers of fleas, endanger life during an epidemic, were destroyed in the Middle Ages, because they were the means of conveying insects that might carry the disease from the sick to the healthy. At the same time that Yersin and Kitasato made their discoveries, another French savant, Dr. Simond, pointed out that the flea was probably the means by which the parasite passed from rat to rat, and from rat to man; and now, through the work of numerous investigators both British and foreign, and more especially through the work of the last commission which had been studying plague in India, the fact had been thoroughly established that the rat was the great carrier of plague, especially across the seas, and that fleas amongst insects were the most important inoculators of the disease. Other insects, however, had to be considered. The feature which made the epidemiology of plague so complex, and the fight against it so difficult, was the wide zoological distribution of the disease. The marmot appeared to be the normal host of the disease, but it might spread to other rodents. The peculiar ground squirrel of California had become infected, and would keep up the epidemic there for years, and it was known in California that an outbreak of plague might occur there at any time. The people were therefore prepared for such a contingency. In India the bandicoot rat became a factor in the epidemiology of the disease, while in Australia rabbits might eventually spread and maintain the epidemic. In Suffolk, hares, rabbits, and other animals had been found infected with plague. Very probably the bacillus in passing from one species of animal to another became adapted to that species, and therefore the disease might be prevalent for many years among such animals, and only a few sporadic cases occur amongst men; but when favourable conditions arose men might become the host for a time. Bed-bugs and lice might also convey the infection, and people that were covered with such vermin might become very dangerous carriers of the disease. Plague had been called the disease of the poor, because they were frequently

covered with vermin, which were the carriers not only of plague but of many other diseases. Very little was known about the most common diseases in this country, such as measles, scarlet fever, diphtheria, whooping-cough and mumps, which were decimating the children, whereas so far as tropical diseases were concerned wonderful progress had been made. A commission which was sent to Africa discovered the cause of the mysterious sleeping-sickness in three months. Was it not time that a thorough investigation was made of such maladies? Most of the diseases had not hitherto been thoroughly understood, because it had not been realised that they were common not only to man, but to a number of the lower animals. Hitherto medical men and veterinary surgeons had worked on different lines; but it was essential, if knowledge was to be obtained about the diseases of man, to ascertain in what way they were connected with similar diseases of animals.

Dr. F. M. SANDWITH said the author did not by any means stand alone in thinking that the plague which already existed in this country was a very serious matter. He thought it was fair to assume that as the plague began in a similar way in many other countries, it would behave in much the same way in this country. He happened to be stationed in Egypt, which had been a great cradle of plague, when the news of the outbreak of the disease in Hong-Kong was first published, and a commission was sent to India for the purpose of ascertaining how the scourge should be treated. At that time, 1888-1889, the work in India was neither scientific nor successful, and the commission brought back word that however the plague was managed in Egypt, the Indian method should not be imitated. It was soon discovered that rats were the chief cause of the spread of the disease; and in that connection he wished to point out that the author was the first person in London, and he believed the first in Europe, to draw the attention of the medical profession to the fact that rats were a very important factor in the spread of plague. As had been stated years ago, plague was not a human disease occasionally communicated to rats; it was, rather, a marmot or rat disease to which man sometimes fell a victim. When all sorts of quarantine methods against men were established, he always regretted he had not the power of a caricaturist to paint a rat or a rat-flea lurking round the corner laughing at human beings making such fools of themselves! We should never be able to prevent plague by destroying only those rats and rat-fleas on board ships in which the captains reported that plague existed; all rats and rat-fleas must be killed on all ships coming from infected ports. The author had reminded them that a better organisation now existed than in times past. There was another comfort in the fact that while man was better equipped than in the days of 1666, the type of rat had also changed, and was less likely to cause plague, because he was a shy creature who did not run about all over the houses, as he still did in India and some other parts of the world. The present knowledge possessed of the disease was all-important. By means of a bacillus, a rat, a flea, and a fool of a man, plague could be produced at any time, provided the temperature was suitable; and if the disease could be produced it also meant that it could be prevented. It would be a crying shame if England, the great pioneer in sanitary matters in the world, ever allowed plague to become rampant in this country, because medical men knew how to prevent it, and it was their own fault if the people did not allow them to do so. It was necessary to have a temperature of between 50° F. and 85° F. to spread plague. That temperature was not obtained in this country in March, but it did occur in England in that modified wintry time which was called summer.

Surgeon-General G. J. H. EVATT said that he was stationed in China as Principal Medical Officer of the troops immediately after the time the author was there, and from the experience he then obtained he was certain there could not be in the whole world a place where every sanitary precaution was more outraged than in Hong-Kong. The overcrowding of the people and the want of sanitary appliances were simply too dreadful for words. From Hong-Kong the plague was passed by means of the opium ships and transports to Bombay, and many millions of our Indian subjects had died as a result. The practical lesson to be learned was the necessity of the general education of the people in the knowledge of the laws of health, and the establishment of a well-paid and well-instructed sanitary service which would be able to do its duty well without the interference of the local authorities. As the manager of a group of schools in the East-End, he paid a visit to one of the schools during the past week, and there saw twenty-four children who were sitting by themselves out of a class of fifty because the teacher said they were lousy. The verminous condition of some of the children in the slums was appalling. With a number of other London physicians, he had endeavoured to get the teaching of hygiene made part of the educational course, and with that object in view deputations had waited upon two Ministers of Education, both of whom, he was sorry to say, were not sympathetic.

The CHAIRMAN, in proposing a cordial vote of thanks to the author for his most interesting paper, said he desired to refer to one point that had been mentioned in order to remove any possible misapprehension. Dr. Cantlie had spoken of the plague in London; what he really meant was plague in the Port of London brought in by the shipping; it had not got ashore. In every large community cases occurred from time to time that raised a suspicion of plague. Every suspicious case that had occurred in London for a very considerable number of years had been

inspected by the author personally, and had also been subjected to bacteriological examination by Dr. Klein; and they had always been able to satisfy themselves that plague was not present. He hoped that condition would continue. Surgeon-General Evatt had referred to the need for removing verminous conditions from London. For a great number of years the sanitary authorities had possessed an Act which enabled them to provide stations for that purpose, but it had been grievously neglected in London. It was a want that the sanitary authorities could provide in London, but there was no power, such as the London County Council, to compel them to move in the matter. Some of the districts had made provision, but in others it was lamentably wanting.

The resolution of thanks was then put and carried unanimously.

Dr. Cantlie, in reply, after thanking the various speakers for the kind remarks they had made and the audience for according him such a hearty vote of thanks, said that the Chairman kept a very keen eye on plague in London. When the scare with regard to that disease first occurred, Sir Shirley Murphy closely investigated several cases that were reported by the doctors. He remembered one Christmas Eve the Chairman and himself inspecting the Chinamen in the opium dens in the East-End of London, searching for a case of plague. It was eventually discovered that a man had died, but whether he had plague or not it was impossible to discover. Everybody in London could sleep soundly in their beds so far as plague was concerned, because they might rest assured that everything it was possible to do was being done by the medical officers of the Port of London. A number of rats had been recently examined in the Port of London, and rats with plague had been found on board several ships and also at the docks. A large number of rats had been destroyed in the Port of London, so that the right thing was being done, because the only way to get rid of the trouble was to destroy the rats. In Sydney sixpence was paid for each rat destroyed, and this proved so effective that it was believed there was not a single rat left in the town. He contended it would also pay the authorities in this country to pay sixpence a tail for each rat destroyed, as, apart from a health point of view, and the getting rid of any fear of plague, £15,000,000 worth of grain would be saved every year, so that the United Kingdom wonld not be so dependent upon America and other countries for its food supplies. The Australians found that it paid, where sheep scab or other infectious disease broke out, to set fire to the country and destroy, if necessary, everything along the track taken by the sheep. Yersin, to whom Dr. Sambon had referred, independently rediscovered the plague bacillus previously discovered by the Japanese. He died as a result of his devotion to science, which was the poorer by his loss.

THE SUEZ CANAL AND ITS TRAFFIC.

Some interesting data regarding the Suez Canal traffic are supplied in the Foreign Office Consular Report on the trade of Port Said and Suez for 1909. From this it appears that the Canal receipts in that year were the highest reached since the opening, and amounted to 120,612,677 francs (£4,825,707) as compared with 108,452,235 francs (£4,338,089) in 1908. The total number of vessels that passed through the Canal in 1909 was 4,239, with a net tonnage of 15,407,527, as compared with 3,795 vessels, of 13,633,283 tonnage, in 1908. Of the former, 2,911 were merchant ships, 972 mail steamers, and 104 men-of-war and transports. The mean net tonnage has risen from 1,000 tons in 1871 to 2,000 tons in 1890, and to 3,635 tons in 1909. The average time of transit for a mail steamer is now fifteen hours, and for a cargo boat eighteen hours. The percentage in number of British ships in 1909 was 60, German percentage being 14, and the Netherlands coming third with 5·9. The transit dues have of course, varied considerably. Originally, in 1869, the tariff was 10 francs per ton, and from 1874 to 1877 it was raised to 13 francs. Since then the tariff has been gradually reduced to 7 francs 25 cents on January 1st last. The 10 francs rate per head for passengers has never been changed.

It may be interesting to recall here that the first concession for the Canal was given to M. Ferdinand de Lesseps by Said Pasha of Egypt in 1854, this being ratified by a second concession in 1856. The company was constituted at Paris in December 1858, with a capital of 400,000 shares of £20 each, of which 176,602 shares were subscribed for by Said Pasha and his successor, the Khedive Ismail. The Khedive's shares were purchased by the British Government in 1875 for £4,076,622. They are now worth about £34,000,000, and bring in an annual revenue of over one million sterling per annum. After numerous soundings in the Gulf of Pelusium, the spot on which the town of Port Said now stands was eventually chosen as the northern entrance, and the first sod was turned by M. de Lesseps on the sea front of Quai Eugénie, April 25th, 1859. The Canal was opened to traffic on November 17th, 1869. The entire length of the Canal is about 100 miles. The navigable dimensions in 1909 were practically double what they were in 1869. The original depth was eight metres, and the original bottom width twenty-two metres; but now the minimum depth is nine and a half metres, and the bottom width forty-five metres. The work of widening and deepening the Canal is being steadily pursued, with the intention of attaining a minimum width of forty-five metres and a depth of eleven metres. At present ships drawing up to twenty-eight feet (eight and a half metres) are allowed to pass through the Canal, but it is anticipated that within four years' time the maximum draught allowed will be increased to thirty feet.

The proposed extension of the Suez Canal Company's lease comprises a variety of financial provisions of considerable importance; but inasmuch as the current lease does not expire till 1968, it is obvious that much may happen before that date, whether in the shape of trans-continental railways or other improvements of communications to modify existing conditions, and thus make consideration of the details of the new lease somewhat premature at the present moment.

ACCIDENTS IN FACTORIES.

In 1908 a Departmental Committee was appointed "to inquire into the causes and circumstances of the increase in the number of reported accidents in certain classes of factories and workshops and other premises under the Factory Acts, and to report what additional precautionary measures are, in their opinion, necessary or desirable." The Committee, under the chairmanship of Mr. H. J. Tennant, M.P., took evidence from fifty-eight witnesses, and spent nine days in visiting factories. Their report has just been issued as a Parliamentary Paper [Cd. 5535].

The Committee are of opinion that the accident risk for the ten years from 1897 to 1907 probably remained almost constant. Since 1907 there has been a tendency for this risk to decrease—a result, no doubt, that is due partly to the Workmen's Compensation Act, partly to the greater experience of employers in the efficient guarding of machinery, and partly to the efforts of the factory inspectors. It is also probable that any increase took place chiefly in the class of unpreventable accidents, while improvement has been effected as regards preventable accidents.

Nevertheless, the Committee think the accident risk is higher than it should be, and they make many suggestions for improving the factory law and the methods of its administration. They dwell upon the importance of co-operation between factory inspectors, employers and workpeople, and recommend periodic conferences between representatives of the three classes for the discussion of industrial dangers and methods of prevention in particular trades or districts. The Committee do not propose that such conferences should supersede the present method of enforcing the law, but they contemplate that they will often have the effect of avoiding the necessity for legal proceedings, and also of enabling the inspector to secure the carrying out more quickly of precautions of a novel kind such as he hesitates to try to enforce by resorting to legal proceedings.

The Committee make various recommendations directed towards strengthening the existing regulations as to the fencing of machinery, the provision of safety appliances, and the cleaning of machinery in motion. They also devote attention to the question of the lifting and carrying of heavy weights, and suggest the desirability of fixing by law the maximum weights which young persons should be allowed to carry. The present system of appointment of factory inspectors is also discussed, but upon this point the opinions of the Committee are somewhat divided.

THE MINING INDUSTRY IN INDIA IN 1909.

The report of the Chief Inspector of Mines in India for the calendar year 1909 shows that, for the first time since the Indian Mines Act came into force, a decrease in the number of workers has to be recorded, and, compared with the preceding year, this decrease amounts to 23,591 operatives, or over 14 per cent. This decrease is not accounted for by a slackness in trade in any one particular mineral, but is due apparently to a wave of industrial depression which swept over the country last year, and has not yet entirely receded.

Coal received a decided set-back in its out-turn, the demand being by no means equal to the supply; and, until collieries were able to accommodate their working to the situation, stocks steadily accumulated, and at the time of the writing of the present report were only just beginning to diminish. The Chief Inspector considers on the whole that the coal industry is in a healthier condition than it was two years ago. Owing to the labour troubles in Australia, Indian coal had an opportunity of entering new markets, and if the shipments contained only clean and carefully-selected coal, the product would undoubtedly strengthen its hold on those markets. The output for 1909 was 11,294,227 tons, as compared with 12,149,020 tons in 1908, showing a decrease of 8 per cent., the diminution being principally in the Jharia district. The Central Provinces area, on the other hand, has increased its output by 10 per cent., and Assam and Baluchistan have also made progress to the extent of 11 per cent. and 16 per cent. respectively. The output of mica has decreased by 709 tons, or 30 per cent., the falling-off applying to all the producing districts in about equal proportions. The Hazanbagh mica tract must be one of the richest mica deposits in the world, but unfortunately mining has been here conducted with utter disregard for the future. Where fairly productive veins are outcropping at the surface, they are worked down as long as the yield is good, the water question not baffling or burdensome, and the labour ample to raise the material cheaply by hand. Should any alteration appear in any one of those conditions, the mine is abandoned, either becoming waterlogged or covered with *débris*, the site of the vein itself often being obliterated, so that no encouragement is offered to any future worker. In the opinion of the Chief Inspector the only way to safeguard the mineral is to impose restrictions as to working upon leaseholders.

The manganese industry has continued the retrograde movement which set in at the end of 1907, there being a great falling away from the high-water mark of that year, when the output

was 642,082 tons, as compared with 494,942 tons in 1908 and 357,205 in 1909. Indian manganese is a very high-grade ore, which is not costly to mine, and must always command a market, excepting during the times of unusual depression. The output of gems from Burma has materially increased during 1909, these being entirely derived from the Mogok branch of the Burma Ruby Mines. Tin, all of which is mined in Burma, has also very considerably increased, though the total output is still only 1,520 cwts. The output of gold has again decreased, the figures for 1909 being 5,615 ozs., as against 7,212 for 1908, all being from the Dharwar goldfield. The outlook, however, is not even as promising as the figures would seem to indicate, as notices have been received to the effect that some of the principal mines were closed down at the end of the year.

The number of fatal accidents in mines that occurred during 1909 was 126, involving the loss of 152 lives, being a decrease of 42 as compared with those of the previous year. In coal-mines, however, the death-rate (10·53 per million tons raised), though diminishing, is still much too high, and, as the Chief Inspector remarks, shows very clearly that the Indian miner has a great deal to learn in the way of taking care of himself, and must be taught how to do it.

HOME INDUSTRIES.

The Coal Industry.—The exports of coal, coke, and patent fuel amounted to 5,222,941 tons in January last, as compared with 4,407,480 tons in January 1910, and with 4,494,504 tons in January 1909, which is satisfactory; but the home industrial demand is not active, and the unusually mild winter has, of course, affected the home household demand. But the aggregate demand is less than might have been expected, having regard to the reviving demand for the world's industrial products. It must, however, be remembered that there were large reserves of coal in stock from the depression of previous years, particularly in January. The prolonged lock-out in the shipbuilding trade seriously reduced the industrial consumption of coal. The shipyards themselves do not require much coal, but the closing of the shipyards meant the closing of some of the steelworks, and the closing or slowing down of some of the ironworks. And, so far as the demand for Welsh coal is concerned—and apart from labour troubles—oil fuel, electric propulsion, and internal-combustion engines may well affect the dominance of Welsh smokeless coal in the marine market. On the whole, however, it may be expected that both in the home and export markets there will be improvement as the year advances.

Short Time in the Cotton Industry.—At the monthly meeting of the general committee of the Master Spinners' Federation held last week, the question of running short time on an organised scale was discussed, and previous to the meeting it was suggested that there might be an effort made to stop the mills engaged on American cotton on Saturday mornings for a couple of months. There is to be a mass meeting to-day at which it will be proposed that the section using American cotton shall ballot on the question of Saturday closing during three months. It is believed that the meeting will approve of the ballot, but it is doubtful whether the necessary majority will be obtained. In the past, 80 per cent. of the members have been sufficient to carry the point, but now it is to be 90 per cent. Anyway it would be some weeks before the proposed curtailment could begin, for at the present time the Lancashire mills are at full swing, and much may happen in a month. The outlook cannot be said to be unfavourable. Raw material prices show decline, it is not likely there will be any scarcity in American qualities, and there will be a plentiful supply of Egyptian cotton. Throughout the world consumption is improving, and there are expectations of a larger turnover in the near future. Shipments continue heavy, and the home trade is showing signs of improvement. But though the general outlook is not unsatisfactory, production continues too large for the requirements of users.

The New Salt Process.—A good deal is being heard just now about a new patent process for the manufacture of salt invented by Mr. James Hodgkinson, of Manchester. It is claimed for this process that it will be able to produce salt at one-fifth of the present cost, owing to the utilisation of the waste steam and hot gases from one pan to precipitate the brine in other pans, the varying degree of heat producing varying sizes of crystals. The vacuum-process salt can be manufactured at 4*s.* per ton or even less, so that if the new process can save four-fifths of the cost of manufacture it means the production of salt at a cost of about 10*d.* per ton. It may be doubted whether that is possible. The Salt Union has just completed large new works at Weston Point, and it is not easy to understand why they should have adopted the vacuum process, as they have done, when they could have availed themselves of the Hodgkinson process, if the explanation is not be found in their belief, presumably reached after due inquiry, that the cost of production cannot be reduced as claimed.

Bank of England Stock.—The present quotation of Bank of England stock is about 260, which, allowing for the half-year's dividend accrued, gives a return to the purchaser of £3 10*s.* 6*d.* This stock at its present price—it is, of course, a Trustee security—is inviting. Eleven years ago it touched 367, which meant a yield to the investor of only £2 14*s.* 6*d.* per cent. Ten per cent. was paid on the stock from October 1896 to October 1903, but since then it has been only 9 per cent. per annum, and the forthcoming distribution will be at the same rate, although it is believed that the

profits of the half-year would have warranted a return to the 10 per cent. distribution. It is curious that the profits for years past have apparently remained stationary. The last return of the half-year has regularly shown that the amount of the "rest," or undivided profit, is sufficient to pay 4½ per cent. for the six months and no more. It is improbable that the profits of the Bank of England do not alter considerably from one year to another, and it may be taken that the directors prefer to utilise surplus profits in writing off investments, or in some other way, at times when the amount would justify a return to 10 per cent. It is believed that the Bank's secret reserves have been largely increased by the policy of retaining the dividend at 9 per cent. per annum.

The Exodus from the Rural Districts.—The tide of emigration from Cumberland, Westmorland, and North Lancashire continues, and is becoming a matter of grave moment to the districts concerned. The emigrants are the flower of the agricultural population and rural artisans, and in many cases they go out not only with a living in their fingers but with money in their pockets. Large parties of young farmers, farm servants old and young, and tradesmen from the villages and small towns, have been leaving in batches of twenty and thirty in a party. Some of the large steamers bound for Canada and the States have taken large numbers of them. Here is one suggestive report of the Candlemas hirings:—"Servants seeking engagements seemed scarcely so numerous as usual, and were mostly composed of youths, with a sprinkling of young women and girls. This was no doubt due to the fact that a large number of agricultural servants have recently emigrated from Cumberland and the Border districts to Canada. Others are due to depart in March, and, what seems to be more serious still for local agriculture, it is apparently the best men who are going."

NOTES ON BOOKS.

THE BACILLUS OF LONG LIFE. By Loudon M. Douglas, F.R.S.E. London and Edinburgh: T. C. & E. C. Jack. 5*s*. net.

A popular account of a popular nostrum. A year or so ago, Professor Metchnikoff's remarkable book on the "Prolongation of Human Life" set everybody drinking sour milk. Some people benefited by it, others suffered, and on a great many it probably had no particular effect whatever. Metchnikoff, after long and laborious investigations, came to the conclusion that senility was caused by the action of putrefactive organisms in the digestive tract, especially in the larger intestine, and that this action could be controlled and prevented by the *bacillus Bulgaricus*, the special organism present in the various preparations of fermented or soured milk used by different races of mankind. Hence a large demand for these preparations, and a considerable consumption of them. Mr. Douglas gives a history of the subject, a description of the original empirical methods by which soured milk was made, and an account of the processes by which the purer and more scientific products of the present day are manufactured.

THE GYROSCOPE. By V. E. Johnson, M.A. London: E. & F. N. Spon. 1*s*. 6*d*. net.

This little volume is founded on a series of articles contributed to the *Model Engineer* in 1909, and it constitutes, as the sub-title indicates, "an experimental study from spinning-top to mono-rail." Beginning with the simplest experiments with a gyroscopic top, Mr. Johnson advances through a number of trials of graduated complexity, to a full and practical explanation of the mono-rail. He also adds directions for the construction of the models with which the experiments should be made. The book is written in very simple language, and should be much appreciated by any lad of a mechanical turn of mind.

GENERAL NOTES.

ENTOMOLOGICAL RESEARCH.—A course of lectures on this subject is being delivered at the Imperial College of Science and Technology by Mr. Maxwell-Lefroy, Imperial Entomologist to the Government of India. As illustrating the importance of the question, Mr. Maxwell-Lefroy, in his first lecture, mentioned that the losses through insect pests to agriculture in the United States were estimated at £60,000,000 a year. He pointed out, too, that practical entomology was not concerned merely with pests. It had to do with such profitable industries as silk manufacture, bee-keeping, and the lac industry, in all of which there was a large scope for improvement. It was, however, recent discoveries as to the spread of disease by insects that had most largely directed attention to the work of the economic entomologist. In the cases of malaria, yellow fever, flariasis (which caused fever, ague, and elephantiasis), plague, cholera, and sleeping-sickness, the transmitting insect was at least as important a factor as the actual organism which caused the disease, and was far easier to deal with. If we were to colonise the tropics, if we were to people them with healthy races, to develop them agriculturally, and to render available the immense amount of raw material they were capable of producing for England's manufactures and trade, it would only be when we had organised entomology and successfully tackled the insect transmitters of disease.

A NEW HEMP-STRIPPING MACHINE.—A hemp-stripping machine, invented by a resident of Manila, and manufactured in Hong-Kong, is being tested in

the Philippines. The machine is an adaptation of the Philippine hand method of hemp-stripping. It consists of several rollers and cutters mounted in a framework 12 feet long, 4 feet high, and 4 feet wide, the machine being mounted on skids, so that it can be drawn about the hemp-fields by an ox or cariboo. The machine strips the hemp from butt to tip, the butt-stripper preparing the stalk for passing through the machine by removing all secondary fibre, with the result that only the first-class fibre is saved. It is claimed by the owners that with twelve men the machine will do the work of forty hand-strippers. Inasmuch as this is the first serious effort to use machines in hemp production, the results are of great interest to all engaged in the industry.

Infusorial Earth in Bohemia.—Kieselguhr, or infusorial earth, occurs in the bogs where the mud is obtained for the famous "moorbäder" (mud-baths) of the Bohemian health resorts. In the vicinity of Soos, a village at the foot of the Erzgebirge, the Kieselguhr is found in small quantities in the mud of the bogs owned by the city of Carlsbad. At Franzensbad the infusorial earth underlies the extensive bogs owned by the city. It is obtainable in almost unlimited quantity. The substance is white, yellowish, or grey in colour, and exists in chalk-like form. It is moulded, burned or otherwise treated for the manufacture of pottery and statuary, gold edges, *papier-maché*, dynamite, putty, adulterants for soap, caoutchouc, and carbolic acid preparations. A non-conductor of heat and electricity, it is employed as a filling in the walls of ice-chests and ice-houses, and for insulation purposes.

The World's Gold Production.—The production of the precious metals, the enormous development of which is one of the characteristics of the last twenty-five years, continued to increase last year, less rapidly however, as regards gold, than in the previous year. The total value of the world's gold production in 1910 amounted to 97 millions sterling as compared with 95 millions in 1909, 92 millions in 1908, and 85 millions in 1907. During the last twenty years, exception being made of the period of the South African War, the year 1896 is the only one in which the rate of progress was lower than in 1910. At the present time the production of gold is four and a half times greater than it was a quarter of a century ago. Then the Transvaal, which now yields gold to the value of 32 millions sterling, produced nothing, while Rhodesia, which twenty-five years ago did not count as a gold-producing country, now yields the precious metal to the value of nearly 3 millions. Western Australia, in the same way, which then produced nothing, now figures for 10 millions. The production of the United States has increased from 7 millions in 1890 to nearly 20 millions at the present time. Last year Russia's gold production amounted to over 9 millions, that of Mexico to 5 millions, British India to over 2 millions, and Canada to over 2 millions.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoon, at 4.30 o'clock:—

March 15.—Colonel Charles Edward Cassal, V.D., F.I.C., "The Adulteration of Food." The Right Hon. the Lord Mayor of London will preside.

Wednesday evenings, at 8 o'clock:—

March 22.—Arthur Charles Davis, F.C.S., Assoc.Inst.C.E., "The Manufacture of Portland Cement."

March 29.—George B. Heming, "Art Education in Jewellery and Goldsmithing and Allied Trades." Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

March 16.—Claude Hamilton Archer Hill, I.C.S., C.S.I., C.I.E., "Education in India." The Right Hon. Lord Northcote, G.C.M.G., G.C.I.E., C.B., will preside.

April 27.—Sir Thomas Henry Holland, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord Avebury, D.C.L., LL.D., F.R.S., will preside.

May 25.—W. R. H. Merk, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

April 4.—Captain R. Muirhead Collins, C.M.G., "Australia and her Resources."

May 9.—F. Williams Taylor, "Canadian Banking."

Cantor Lectures.

Monday Evenings, at 8 o'clock:—

Professor J. A. Fleming, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

Syllabus.

Lecture II.—March 13.—"The Appliances and Processes of Electric Heating." Resistance and Arc Heating—Direct and Inductive Methods—Electric Furnaces of Girod, Heroult, Kjellin, Keller, Stassano, Ferranti, Rodenhauser, and others—Resistance Furnaces for Chemical Operations, both at Moderate and Very High Temperatures—Experimental Models.

Lecture III.—March 20.—"The Technical Applications of Electric Heating." The Manufacture of Graphite, Carborundum, Calcium Carbide, Quartz Glass, Aluminium, Ferro-Alloys, and Iron and Steel in Electric Furnaces—Electric Welding—Electric Furnaces for Metallurgical and Chemical Operations.

Lecture IV.—March 27.—"The Domestic Applications of Electric Heating." Electric Water Heating—Its Cost and Economy—Air Heating by Electric Radiators and Convectors—Electric Cooking—Various Systems and Types of Utensil critically discussed—The Advantages and Drawbacks in Comparison with other Methods of Culinary Heating.

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

Dates to be hereafter announced :—

FRANK M. ANDREWS, "Architecture in America."

Professor RAOUL PICTET, "Les Basses Températures."

Sir WILLIAM ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

NOEL HEATON, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

HENRY L. HEATHCOTE, B.Sc., "Wheels, Ancient and Modern, and their Manufacture."

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. J. A. Fleming, "Applications of Electric Heating." (Lecture II.)

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. (Graduates' Meeting.) Mr. A. J. Bremner, "The Balancing of Engines."

Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. A. E. Stanley Smith, "Some Responsibilities of Brewers under the Factory Acts."

London Chamber of Commerce, Oxford-court, Cannon-street, E.C., 2.30 p.m. Mr. E. Crammond, "Gold Reserves in Time of War."

Surveyors, 12, Great George-street, S.W., 8 p.m. 1. Messrs. H. F. Bidder and W. Vaux Graham, "Judicial and Parliamentary Decisions with regard to Rights in Underground Water since 1907." 2. Discussion on Mr. W. R. Baldwin-Wiseman's paper, "The Conservation of our National Water Resources."

Geographical, Burlington-gardens, W., 8.30 p.m. Dr. T. G. Longstaffe, "A Pioneer Journey in the Purcell Range, British Columbia."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. J. A. Gotch, "The Burlington-Devonshire Collection of Drawings."

Engineers, Junior Institution of, at the Royal United Service Institution, Whitehall, S.W., 7.30 p.m. Mr. Geoffrey Brooks, "The Design of a Modern Brewery and Plant."

TUESDAY, MARCH 14...Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Discussion on School Lighting.

Asiatic, 22, Albemarle Street, W., 4 p.m. Dr. H. Hirschfeld, "Recent Theories on the Origin of the Alphabet."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. A. E. H. Tutton, "Crystalline Structure: Mineral, Chemical and Liquid." (Lecture III.).

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Philip Dawson, "The Electrification of a portion of the Suburban System of the London, Brighton and South Coast Railway."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. C. F. Lan-Davis, "Iris Diaphragms."

Faraday Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. 1. Messrs. G. E. Bairsto and R. Mercer, "Some Properties of Aluminium Anode-Films." 2. Messrs. F. P. Burt and R. W. Whytlaw-Gray, "The Weight of a 'Normal' Litre of Hydrogen Chloride and the Atomic Weight of Chlorine." 3. Mr. Ernest Vanstone, "A Physico-Chemical Study of Mercury-Sodium Alloys or Sodium Amalgams." 4. Messrs. S. W. J. Smith and W. F. Higgins, "On Surface Effects between Mercury and Certain Solutions, and an Electro-Chemical Method of Estimating Dissolved Oxygen."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Mr. Ben H. Morgan, "Empire Trade Relations."

Sanitary Institute, 90, Buckingham Palace-road, S.W., 8 p.m. Dr. Leonard Hill, "Rescue Work in Mines," with a demonstration of apparatus in use.

WEDNESDAY, MARCH 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Colonel Charles E. Cassal, "The Adulteration of Food."

Meteorological, 25, Great George-street, S.W., 7.30 p.m. Professor H. H. Turner, "What can we Learn from Rainfall Records?"

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Dr. Ralph Vincent, "The Morphology of the Organisms concerned in the Production of Acute Intestinal Toxaemia in Infants." 2. Mr. F. W. Watson Baker, "Anomalies in Objective Screw Threads." 3. Mr. E. M. Nelson, (*a*) "Some New Objectives and Eye-pieces by R. Winkel, of Gottingen"; (*b*) "An Objective Mount with an Iris"; (*c*) "The Variable Microscope." 4. Señor Domingo Orueta, "Apparatus for Microphotography with the Microscope standing in any Position, especially in Inclined Position."

THURSDAY, MARCH 16...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. Claude H. A. Hill, "Education in India."

National Life-Boat Institution, at the United Service Institution, Whitehall, S.W., 3.30 p.m. Annual General Meeting.

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Mr. R. S. Adamson, "An Ecological Study of a Cambridgeshire Wood." 2. Mrs. Scott, "*Traquairia*; an Organism from the Carboniferous Rocks." 3. Miss S. M. Baker, "On the Brown Seaweeds of the Salt Marsh."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Address by the President, Mr. E. B. Ellington.

Chemical, Burlington House, W., 8.30 p.m. 1. Mr. J. Wade, "Apparatus for the Maintenance of Constant Pressures above and below the Atmospheric Pressure: Application to Fractional Distillation." 2. Messrs. W. G. Prescott and S. Smiles, "The Interaction of Aromatic Disulphides with Sulphuric Acid."

Royal Institution, Albemarle-street W., 3 p.m. Professor Arthur Keith, "Giants and Pygmies." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. J. C. Warburg, "Selection of Autochromes."

Historical, 7, South-square, Gray's Inn, W.C., 5 p.m. Mr. H. E. Malden, "The Holding of Cardigan Priory by Chertsey Abbey."

Numismatic, 22, Albemarle-street, W., 6.30 p.m. Mr. F. A. Walters, "The Stamford Find."

Philatelic, 4, Southampton-row, W.C., 6 p.m. Mr. S. Chapman, "The Early Issues of Mexico."

FRIDAY, MARCH 17...Royal Institution, Albemarle-street, W., 9 p.m. Mr. J. H. Balfour-Browne, "Water-Supply."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. Alwyne Mead, "The Production of Water-Gas."

SATURDAY, MARCH 18...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Radiant Energy and Matter." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,043. VOL. LIX.

FRIDAY, MARCH 17, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 20th, 8 p.m. (Cantor Lecture.) Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." (Lecture III.)

WEDNESDAY, MARCH 22nd, 8 p.m. (Ordinary Meeting.) ARTHUR CHARLES DAVIS, F.C.S., Assoc.Inst.C.E., "The Manufacture of Portland Cement."

CANTOR LECTURE.

On Monday Evening, March 13th, Professor J. A. FLEMING, M.A., D.Sc., F.R.S., delivered the second lecture of his course on "Applications of Electric Heating."

The lectures will be published in the *Journal* during the summer recess.

"OWEN JONES" PRIZES FOR INDUSTRIAL DESIGN.

The Board of Education have issued a notification to the effect that works submitted for the National Competition, and certain other works, are to be addressed to the Secretary, Board of Education, South Kensington, London, S.W. These works include those submitted for the "Owen Jones" Competition.

EXAMINATIONS.

The number of entries for the Society's Commercial Examinations, which commence on April 3rd, is 37,124. The number of centres at which the examinations will be held is 459. Last year there were 33,830 entries from 439 centres.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1911 early in May next, and they therefore invite members of the Society to forward to the Secretary on or before Saturday, April 1st, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, etc.

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S.

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal.

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin.

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

In 1884, to Captain James Buchanan Eads.

In 1885, to Mr. (afterwards Sir) Henry Doulton.

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham).

In 1887, to HER MAJESTY QUEEN VICTORIA.

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S.

In 1889, to John Percy, LL.D., F.R.S.

In 1890, to Dr. (afterwards Sir) William Henry Perkin, F.R.S.

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.

In 1892, to Thomas Alva Edison.

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.

In 1894, to Sir Joseph (now Lord) Lister, F.R.S.

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S.

In 1896, to Professor David Edward Hughes, F.R.S.

In 1897, to George James Symons, F.R.S.

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S.

In 1899, to Sir William Crookes, F.R.S.

In 1900, to Henry Wilde, F.R.S.

In 1901, to HIS MAJESTY KING EDWARD VII.

In 1902, to Professor Alexander Graham Bell.

In 1903, to Sir Charles Augustus Hartley, K.C.M.G.

In 1904, to Walter Crane.

In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.

In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.

In 1907, to the Earl of Cromer, G.C.B., O.M., G.C.M.G., K.C.S.I., C.I.E.

In 1908, to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.

In 1909, to Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S.

In 1910, to Madame Curie.

A full list of the services for which the medals were awarded was given in the last number of the *Journal*.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 15th, 1911; The Right Hon. the LORD MAYOR OF LONDON (Sir Thomas Vezey Strong), in the chair.

The following candidates were proposed for election as members of the Society :—

Eccles, Ernest Edward, M.I.E.E., Foyers, Lochness, Scotland.

Rahder, Christiaan Lydius, LL.D., Sourabaya, Java, Netherlands East Indies.

Ritchie, W. W., District Postmaster, Chengtu, West China.

Sang, Alfred, 96 Boulevard de Versailles, St. Cloud, Seine-et-Oise, France.

Stewart, Professor Louis Beaufort, University of Toronto, Toronto, Canada.

The following candidates were balloted for and duly elected members of the Society :—

Curtis, Miss Gertrude M., 5, Victoria-street, S.W.

Hayward, Johnson, Tuesley Lane Cottage, Godalming, Surrey.

Hebdon, William, 56, Tresillian-road, St. John's, S.E.

Johnston, Edward Hamilton, I.C.S., Terlings, Harlow, Essex.

Willott, Frederic John, The Aluminium Corporation, Limited, Wallsend-on-Tyne.

The paper read was—

THE ADULTERATION OF FOOD.

By CHARLES E. CASSAL.

The subject dealt with in this paper is one of very wide scope, and is surrounded by many difficulties—scientific, legal, commercial and social. Its aspects are many and various, its subsidiary ramifications are widely extended and often highly complicated, and it is impossible, within the narrow limits of a single paper or lecture, to do more than sketch out its main features in a manner that will enable the general public to appreciate their significance and relative importance.

Young and old, rich and poor, in all so-called civilised communities, are affected by the existence of the food-adulteration evil, and, in this country—which, among the nations called civilised, was at one time the pioneer in introducing preventive and repressive legislation, but which has failed to maintain its past leading position—the state of things to-day is such that the formation of a National Society for the Prevention of Adulteration—the Society I am representing here—is not only more than justified, but is absolutely necessary in order that the people may be educated, and that, in consequence, the strong public feeling, without the existence of which effective reform cannot be brought about, may be created.

The history of adulteration presents many features of considerable interest, and I am almost tempted to plunge into the annals of an inglorious past, and to put forward a few of the startling instances of abominable fraud which are to be found in that history. Experience, however, has taught me that when a lecturer on this subject follows that course he runs the risk of being misunderstood unless he takes the most elaborate precautions and makes it perfectly clear that the instances of villainy which he mentions belong to a past age, or are more or less apocryphal. Without those special precautions in the way of elaborate explanation

he is liable to be made responsible for stating that coffee is largely composed of baked horses' livers, that bread is commonly prepared from "putrid and rotten" materials, that moist sugar is heavily adulterated with sand, and so forth. Moreover there are certain persons who wilfully misinterpret the remarks made, and who put them forward, without their context, with the object of making it appear that the advocates of the introduction of more stringent measures for the prevention of adulteration do not know what they are talking about, and that all their statements are exaggerated and unworthy of attention. To those who may be interested in the historical branch of the subject, a perusal of Part I. of Mr. Wynter Blyth's valuable work on Foods* may be recommended. For my present purpose a few brief quotations from that book will be sufficient:—

"Before adulteration commences, commerce must develop. In primitive states of society, there may be knavish tricks, ignorant bartering, substitution of bad for good, falseness and meanness of all kinds, but no systematic sophistication is possible. Again, in the semi-pastoral state . . . in which the food of a family is raised from the soil on which they dwell . . . commercial frauds are unknown or undeveloped."

"There are several notices of ancient sophistication practised by the Greek and Roman traders; but it is from the Middle Ages that the most copious and interesting materials for a history of adulteration are obtained—a page of history but little explored, yet abounding with curious facts more or less illustrative of the manners of the times. The mixing or, rather, alloying of gold and silver with the baser metals may be justly considered as being of the nature of adulteration, and has prevailed contemporaneously with the art of coinage. The well-worn tale of the detection of the base metal in the crown of Hiero by Archimedes, some two and a half centuries before Christ, may be accepted as probably the earliest instance of the scientific detection of adulteration. The process used by the philosopher of Syracuse when thus discharging the duties of a *public analyst* (the determination of specific gravity) is quantitative as well as qualitative, and, though purely physical, is used daily by all engaged in practical chemistry. Pliny, among other matters, alludes to the frauds practised by bakers, for they added to the bread a white earth, soft to the touch and sweet to the taste. . . . The adulteration of wine in Athens necessitated the appointment of a special inspector, whose duty it was to detect and stop these practices. Greek history has handed down the name of one Canthare, who excelled in ingenious mixtures, and knew how to impart the flavours of age and maturity to new wines. His ingenuity was such that it was commemorated in the proverb: 'Artificial as Canthare.' In Rome, also, wine was much tampered with; even the rich, according to Pliny, could not obtain the natural wines of Falerno, for they were adulterated in the cellars, and certain wines from Gaul had an artificial colour given to them by means of aloes and other drugs. . . ."

"In our own country, and in Europe generally, from the eleventh century onwards, the bakers, the brewers, the 'pepperers,' and the vintners, were most frequently accused of corrupt practices. . . . In England the trades of the druggist and the grocer were combined. Drugs and groceries were sold in the same shop, and they were under the same regulations until 1617, when the apothecaries separated themselves from the grocers. Very soon after they had become a distinct body, they began to complain of the frauds and artifices of the grocers. . . ."

The punishments inflicted for the crime of adulteration in past times, in those cases where, with the limited means then available, it was possible to prove the commission of an offence, or, at any rate to prove this to the satisfaction of the authorities, did not err, as a rule, in the direction of leniency as is very generally the case in this country at the present day. It has been suggested that the infliction of some of these punishments might, with advantage, be revived, and I am not sure that as regards certain persons the re-establishment of those punishments might not be beneficial to them and to the community. Mr. Wynter Blyth cites some curious examples:—

"Alan de Lyndseye, baker, was sentenced to the pillory because he had been convicted of baking *pain demayn* that was found to be of bad dough within and good dough without, and because such falsity redounds much to the deception of the people who buy such bread."

This person got into trouble again shortly afterwards—a not uncommon occurrence with adulterators—for we read that:—

"Alan de Lyndseye, baker, and Thomas de Patimere, baker, were taken and brought before the Mayor and Aldermen and sentenced to the pillory for selling bread made of false, putrid, and rotten materials, through which who bought bread were deceived and might be killed.

"It is recorded that in certain cities 'the offender was taken round the town in the cart in which the refuse of the place had been collected,' and that 'to this degradation was often added corporal chastisement.' In Paris, in 1525, a baker convicted of 'false bread' was condemned by the court 'to be taken from the Chatelet prison to the cross before the *Eglise des Carmes*, and thence to the gate of Notre Dame and to other public places in Paris, in his shirt, having the head and feet bare, with small loaves hung from his neck, and holding a large wax candle lighted, and in

* "Foods: their Composition and Analysis." By A. Wynter Blyth. Fourth edition. 1896.

each of the places enumerated he was to make *amende honorable*, and ask mercy and pardon of God, the king, and of justice for his fault.'

"In Germany, during the Middle Ages, it appears that 'those who adulterated foods or drinks . . . were punished severely, with painful and dishonouring penalties, such as public exposure of the fraud and whipping at the gate.' . . . In the fifteenth century, 'in some places the delinquent was put in a basket at the end of a long pole and ducked in a muddy pool.' 'In 1435, the taverner Christian Corper and his wife were put on a cask in which he had sold false wine, and then exposed in the pillory. The punishment was adjudged because they had roasted pears, and put them into new sour wine, in order to sweeten the wine. Some pears were hung round their necks like unto a paternoster.'"

Owing to the inadequate means available for the detection of adulteration up to comparatively very recent times, the few records of detected offences which have come down to us cannot be regarded as in any way representing the extent to which adulteration of all kinds was practised in the past. It is only during the last fifty years that the existence of this monstrous evil has attracted the serious attention of the Governments of civilised countries. The first general Act passed in this country was the Act of 1860. Before that date "individual articles, such as tea, coffee, chicory, beer, and wine, were legislated for by special statutes, the object of which was, for the most part, to prevent the defrauding of the revenue—the health of the purchaser, and the injury done to him, being somewhat less considered, although not lost sight of." In 1850 Mr. Wakley, the then editor of the *Lancet*, established an "Analytical Sanitary Commission," under the direction of the late Dr. Hassall, and, in the first number of the *Lancet* for 1851, the Commission's preliminary report appeared. In 1855 Dr. Hassall collected the articles which had been published in the *Lancet* into a volume entitled "Food and Its Adulterations," and, as a direct result of the campaign initiated by Mr. Wakley and Dr. Hassall, a Parliamentary Select Committee was appointed to consider the whole question in 1855. Upon the report of this Committee the first General Adulteration Act was drafted and became law in 1860. A further Act was passed in 1872; but, as these Acts were not found to work satisfactorily, and as for this reason and other reasons they were ineffective, another Select Committee was appointed in 1874. The report of the Committee led to the passing of the Sale of Food and Drugs Act of 1875, which, with the Amendment Act of 1879, and the subsequent Sale of Food and Drugs and Margarine Acts of 1887, 1899 and 1907, form the existing law.

The state of things existing when the *Lancet* Commission was carrying out the investigations referred to—a state of things which must have been at least as bad before the establishment of the Commission, and which undoubtedly continued to be almost, if not quite, as bad for several years after the publication of the Commission's reports—can best be appreciated by a study of the articles which appeared in the *Lancet* from 1851 to 1854 or of Dr. Hassall's book. It is only needful to observe here that while many forms of adulteration detected at that time have now disappeared, owing to the repressive and deterrent effects of our existing laws—such as they are—laxity and inadequacy of administration and the ineffectiveness of the law in certain directions, lead to the reappearance of some of these older forms of adulteration and encourage the perpetration of new forms of crime even more objectionable, and, in some cases, more dangerous, inasmuch as they are more insidious, more scientific, and far more difficult to detect. Although many of the grosser forms of adulteration detected in past years are now no longer practised, new forms of sophistication are constantly being introduced—very generally under the guise of alleged "scientific improvements," or with the shallow excuse that what has been done has been rendered necessary in order to meet "a public demand," or the requirements of "the public taste." *The adulterator ye have always with you*, and experience leads to the conclusion that the morality of deliberate criminals in the matter of adulteration cannot be held to exhibit any real or substantial improvement in our day. To some extent and in some directions they may have been dragooned into virtue, or into an assumption of virtue, but daily evidence clearly indicates that the evil desire to obtain illegitimate gains without regard for their neighbours' rights, interests, health, or even life, is still existent in their sordid souls, unchanged and undiminished. As affording incontrovertible proof of what I now say, I may direct attention to the records of cases of prosecution under the Food and Drugs Acts which have been published every month in the *British Food Journal* since the commencement of the year 1899 until the present time. Taken as a whole these records constitute what can only be regarded as a crushing indictment—especially in view of the fact that practically all

the cases in question have been recorded because they contain some special point — or some special points—of interest, and represent only a fraction of all the cases heard during the past decade. Assuming the legality of the infliction, during that period, of the ancient punishment previously referred to, which consisted in hanging specimens of the adulterated or defective article round the necks of the condemned delinquents, and in exposing those individuals—after a ride round the town in the dust-cart, and prior to the "castigation at the gate"—in some public place such as Trafalgar-square, or the front of the Royal Exchange, what an edifying spectacle might have been provided for the populace. The necklaces which might have been prepared for the purposes of such an exhibition would have been interesting and very varied in their characters. Bottles of milk containing added water, of milk denuded of fat, of milk containing boric acid or formaldehyde; rolls of "butter" largely or mainly composed of foreign fat or loaded with an excess of water, or containing an excess of boric acid "preservative"; wedges of "cheese" made up with foreign fat or containing next door to no fat at all; pots of "cream" dosed with boric acid; blocks of margarine containing "soft paraffin"; bladders or kegs of "lard" containing generous proportions of beef stearin, cotton-seed oil, or cocoa-nut fat; packets of "coffee" largely or mainly consisting of chicory; tins of "delicacies," such as potted meats and fish, prepared from highly questionable raw materials and duly embalmed by liberal doses of boric acid; bags of meat found to be diseased and unfit and dangerous for human food; fragments of fish, flesh, and fowl, on the verge of putridity, and plentifully sprinkled with boric acid powder for the purpose of masking the signs of decomposition; flasks of "brandy" devoid of spirit distilled from wine; jars of potato-spirit whisky; bottles of lime juice, lemon juice, "cordials," and non-alcoholic drinks plentifully dosed with salicylic acid; and tins or bottles of preserved peas, beans, and spinach well "greened" by the addition of sulphate of copper. The list is far from being exhausted, but it seems unnecessary to go further. The indictment is a long one, and it is much more than sufficient to prove the case.

The term "Adulteration" in the ordinary or popular sense has a restricted meaning. It now possesses a meaning which the word itself does not imply. "Adulteration," *per se*, in its restricted sense, is commonly held to mean the admixture with a given article of some substance foreign to that article, or the addition to that article of some substance naturally present in it, so that the resulting mixture contains an excess of the constituent in question—as in the cases of the addition of water to milk or butter. But it has become convenient, and, in fact, necessary, to give a more extended meaning to the term "adulteration." Under the existing law, an article which exhibits, on analysis, a substantial deficiency in an important constituent—such as a liquid sold as "milk" which is found to contain less than 3 per cent. of fat—must be classed as "adulterated." An article which, in its natural state, normally contains an impurity, the presence of which is due to the conditions of production or collection, becomes "adulterated" if the amount of that impurity is found to be substantially in excess of a particular limit—as in the case of the presence of sandy matter in pepper. Again, owing to the variations in the compositions of natural products, it is not always possible to draw a rigid line of demarcation between the genuine and the adulterated article. There is a borderland of varying extent in different cases, and the operation of definitely placing a given article on one side of that borderland or on the other is often a matter of extreme difficulty. One result of this is that in regard to all natural products the most lenient limits and standards must be adopted in order that no injustice may be done to the manufacturer, producer, or vendor, in the administration of the Acts of Parliament, which are, in reality, criminal Acts. In this country there exist, as yet, practically no definitions having the force of law as to what is to be held to constitute "adulteration" in the cases of a great many articles. Each case brought before the courts has to be fought out on its merits, and conviction, or dismissal of the charge made, must depend on the evidence adduced and on the effect produced by that evidence on the mind of the adjudicator. In some countries, notably in the United States, and in one or two of our Colonies, the authorities have gone a long way ahead of us in this matter. In the United States the accepted view has been formulated thus:—

"Except in special cases, a food in general is deemed to be adulterated if anything has been mixed with it so as to reduce or lower its quality or strength; or if anything inferior or cheaper has been substituted wholly or in part therefor; or if any valuable constituent has been abstracted wholly or in part from it; or if it consists wholly

or in part of a diseased, decomposed, or putrid animal or vegetable substance; or if by colouring, coating, or otherwise it is made to appear of greater value than it really is; or if it contains any added poisonous or injurious ingredient." *

This definition is fairly satisfactory so far as it goes, but it is insufficient in extension. The main principle on which our Sale of Food and Drugs Act of 1875 is based should be included in it, namely, that under any circumstances an article shall be deemed to be adulterated if it can be proved that that article is not of "the nature, substance, and quality" demanded by the purchaser, or if it is not of "the nature, substance, and quality" which the purchaser is to be presumed to have expected.

In Great Britain and Ireland the administration of the Food Adulteration Acts is in the hands of the local authorities—the borough and city councils and the county councils. Under the provisions of these Acts the local authorities are not only empowered, but are required to appoint persons of knowledge, skill and experience as public analysts, whose duty it is, in consideration of such remuneration as may be agreed upon, to analyse samples of foods and drugs submitted to them by inspectors specially appointed under the Acts to take samples of articles exposed for sale, or submitted by private purchasers who have complied with certain conditions laid down in the Act of 1875. Within a specified time the public analysts are required to issue certificates showing the conclusions at which they have arrived in regard to the nature of the samples submitted to them. Up to the present the onus of advising the local authorities as to whether a given sample is, or is not, adulterated has rested entirely on the shoulders of the public analysts, and this ought not to be. It was, and it is, the duty of the Government for the time being to carry out, and to bear the expense of carrying out, the necessary investigations; and, on the results of those investigations, to lay down directions and regulations for the proper and effective administration of the Acts. It is satisfactory to be able to say that the truth of this principle has, at length, been recognised. Within the last few years a new department has been established at the Local Government Board—the Department of the Inspector of Foods—under the able direction of Dr. G. S. Buchanan. This department has already done a great deal of excellent work, and it may be confidently expected that it will do a great deal more. Unfortunately arrangements do not yet appear to have been made—in so far as the Food and Drugs Acts are concerned—whereby the recommendations made by the department may be given the force of law.

The Board of Agriculture and Fisheries now possesses powers to make regulations and to lay down limits and standards in regard to certain articles of food such as milk, cream, butter and cheese, and has exercised those powers with respect to milk, to separated and skimmed milk, to butter; and also with respect to so-called "milk-blended butter" in so far as the allowable percentage of water is concerned; but the Board has recently declined to accede to requests, put forward by various borough councils, to the effect that the Board should lay down standards and limits for fat, water, and other constituents for the different kinds of cheese sold in this country.

The solution of the difficulty of deciding what is and what is not to be regarded as constituting "adulteration" is, I think, the establishment of a properly-constituted Court of Reference—as recommended by the Food Products' Adulteration Committee of the House of Commons in 1896—which would act in concert with the Foods Department of the Local Government Board, and with the Board of Agriculture should necessity arise. In reporting on this matter the Committee of the House of Commons made the following statements, *inter alia*:—

"Your committee think that the question of the practicability and expediency of fixing food standards should receive the consideration of a specially constituted scientific body familiar with questions of analysis and the chemistry of food, and they recommend that such a body should be established . . . The Court of Reference constituted on the lines indicated should be empowered to make such orders as they think proper respecting standards of the quality and purity of food, and such orders should, when confirmed by a Secretary of State, have the force of law. It appears to your committee preferable to fix standards in this way than by means of an Act of Parliament. The former course would more readily admit of the alteration of a standard if for any reason such a proceeding were found desirable . . . The proposed Court of Reference should be entrusted with the duty of collecting and communicating to public analysts and others information as to new and unrecognised forms of adulteration, and also of examining and pronouncing upon new methods of analysis."

I concur in these views. In fact I may now say that the evidence upon which the portion of the Committee's Report relating to the establishment of a Court of Reference was founded, although not actually given before the

* "Food Inspection and Analysis." By Albert D. Leach. New York: 1904.

Committee by myself, was put forward mainly at my instance. It is not to the public interest that scientific officials who have to carry out such duties as those of a public analyst should have the heavy responsibility of deciding what is and what is not to be regarded as constituting "adulteration" thrown upon them. It is not fair and it is not reasonable that individual public analysts should be compelled to carry out lengthy and expensive scientific researches —which they have neither the time nor the means to carry out—and that they should find themselves repeatedly compelled to do this simply because successive Governments have shirked their responsibility and have not taken the necessary steps to have these matters studied at the Government expense. Under existing conditions the public analyst is placed in a very false and a very difficult position. He may have issued a certificate—based upon what knowledge he may have been able to gain in regard to the article dealt with—the terms of which indicate to his authority that an offence has been committed. He has to defend that certificate in a Court of Law—probably in the face of powerful opposition, and of a defence, in the preparation of which no expense has been spared. He is frequently subjected to an insulting cross-examination--in the course of which his good faith and his professional capacity are generally called in question—and he has to prove his case to the satisfaction of the presiding legal luminary who, while no doubt learned in the law, cannot always be expected to be learned in anything else. In the absence of legal standards and limits and of accredited technical advisers to the Bench, cases involving most difficult and recondite scientific points are sandwiched between cases of assault and petty larceny, and have, under our present system, to be threshed out in police-courts at great expense both of time and money; and, unless he possesses some sort of scientific knowledge, the unhappy magistrate is compelled to rake up from a dim and distant past the shadowy recollections of his school chemistry, and to struggle with little arithmetical problems which it is not always fair to expect him to deal with. Recent striking examples of our cumbrous and unsatisfactory course of procedure are afforded by the Court fights over boric acid in cream, "cornflour" consisting of rice starch, silent spirit in brandy and whisky, and cocoa shell in cocoa, some of which have led to the appearance of the newspaper head-lines, "What is Brandy?" "What is Whisky?" "What is Cocoa?"—questions which, in spite of all the trouble and expenditure involved in considering them, have not as yet been settled by any finally binding decisions, or by any authoritative pronouncements from a Governmental source.

The more common forms of food adulteration which come before the Public Analyst at the present day may be briefly mentioned here. *Milk*:—(1) The addition of water. (2) The abstraction of fat (*a*) directly by surface skimming, leaving the liquid known as "skimmed milk," or (*b*) by the use of a centrifugal separator, whereby practically the whole of the fat can be removed, leaving the liquid known as "separated milk"; or (*c*) indirectly by the admixture of separated milk with whole milk. (2) The addition of water and the abstraction of fat. (3) The addition of "preservative" chemicals or drugs, such as boric acid and borax or mixtures of these two substances, or the solution of formaldehyde, known as "Formalin"—a most powerful and dangerous substance—or some other chemicals. (4) The addition of colouring matters, many of those now used being of coal-tar origin—a proceeding which serves the purposes of fraud by giving a false appearance of richness to the milk and by deluding the purchaser accordingly. (5) The production of deficiencies in the normal constituents of milk by the improper feeding or the improper management of cows, whereby milk having the same composition as milk directly adulterated with water or directly deprived of a portion of the fat, may be yielded. This proceeding may justly be regarded as "adulteration at the other end of the cow" and should be looked upon and treated as an offence.

Butter.—(1) The admixture of "foreign fat," that is, the admixture with genuine butter of a fat or fats not having the composition and characters of butter fat. This is generally accomplished by mixing "margarine"—a substance prepared in imitation of butter from the fat of cattle—with the butter. Cocoa-nut oil is now largely used for the adulteration of butter, and is very generally used in conjunction with animal fat. (2) The incorporation of an excess of water with butter. (3) The addition of "preservative" chemicals, generally boric acid or borax, or mixtures of the two.

Cream.—(1) The addition of preservative chemicals, generally boric acid preparations. (2) The use of certain preparations for the purpose of giving a thick appearance to cream (gelatine and so-called "sucrate of lime"). This,

however, is at present a rare occurrence. Cream is now largely prescribed by medical men for children and invalids.

Cheese.—(1) Deficiency in fat owing to the use of separated milk or skimmed milk in the manufacture, the deficiency not being permissible if the article is not sold as "separated-milk-cheese" or "skimmed-milk cheese." (2) The presence of foreign fat—fat other than milk fat, the cheese having been made from separated milk and animal fat. (3) Excess of water. (4) In the case of certain cheeses sold as "gorgonzola" the attachment of artificial rinds composed of barytes and tallow.

Lard.—(1) Presence of water. (2) Addition of beef or mutton stearin. (3) Addition of cotton-seed oil. (4) Addition of vegetable fats, such as cocoa-nut oil or palm-nut oil, or substitution of these for genuine lard. (5) Addition of paraffin wax and "soft paraffin."

Tea.—(1) Presence of exhausted and redried tea leaves. (2) Presence of leaves foreign to tea. Although it is possible that these forms of adulteration are still practised, the number of samples of tea taken under the Acts is comparatively so small that no definite conclusions are possible. No cases have been recorded for several years.

Coffee.—The addition of chicory or other roasted foreign vegetable substances.

Cocoa.—(1) The addition of starch foreign to cocoa—such as sago-starch, potato-starch, and arrowroot, the mixture being sold as "cocoa." (2) The addition of sugar. (3) The addition of the powdered shell of the cocoa-bean.

Chocolate.—(1) The use of cocoa containing cocoa-shell, or the substitution of cocoa-shell for cocoa in the manufacture of the article. (2) The addition of foreign starches. (3) The addition of foreign fats.

Brandy.—(1) The substitution of coloured and flavoured silent spirit, or the adulteration of genuine brandy with silent spirit—in other words, with "plain" alcohol produced from any raw material from which it can be obtained by chemical processes. (2) The addition of water.

Whisky and Rum.—(1) Adulteration with silent spirit or substitution of coloured and flavoured silent spirit for the genuine article. (2) The addition of water.

Bacon, Ham, Poultry, Fish.—The addition of preparations of boric acid.

Preserved or Potted Meats and Fish.—The addition of preparations of boric acid.

Preserved Green Vegetables (peas, beans and spinach).—The addition of sulphate of copper for the purpose of imparting an artificial green colour to the articles.

Vinegar.—(1) The addition of water. (2) The addition of mineral acids. (3) The substitution of coloured solutions of "wood acid" for malt vinegar.

Mustard.—(1) The addition of wheat flour and turmeric powder. (2) The abstraction of mustard oil.

Pepper.—(1) The presence of an undue amount of sandy matter. (2) The addition of rice flour or rice starch or other foreign starch. (3) The addition of ground woody material, such as ground olive stones.

Lemon Juice, Lime Juice and Non-Alcoholic Drinks.—The addition of salicylic acid—a powerful and dangerous drug—for "preserving" purposes.

Beer.—(1) The addition of water. (2) The addition of saccharin. (3) Contamination with arsenic. In bottled beers, the addition of salicylic acid.

Wine.—(1) The addition of water. (2) The addition of salicylic acid. (3) The addition of sulphurous acid or compounds thereof. (4) The use of coal-tar dyes or other forms of artificial colouring matter.

Confectionery.—(1) The addition of paraffin wax. (2) The use of ferruginous earths for colouring. (3) The use of coal-tar dyes for colouring. Many of these dyes are known to be poisonous, while as to others little or nothing is known in regard to their possible effects on the consumer.

Tinned Foods.—(1) Contamination by tin and lead. (2) Unwholesome or partly decomposed condition.

Jams and Preserves.—(1) The use of starch-glucose instead of cane or beet sugar. (2) The substitution, in whole or in part, of one fruit for another. (3) The addition of salicylic acid.

Rice and Barley.—Coating the grains with powdered talc ("French chalk").

The foregoing statement is only to be regarded as a sketch. It would be wearisome to enter into further details in this direction, but some observations on certain points are desirable.

The addition of chemical "preservatives" to articles of food is a most objectionable practice, which has enormously increased of late years. The substances used consist principally of boric acid, borax, and mixtures of these two substances; salicylic acid, formaldehyde, and sulphurous acid and sulphites. The addition of these drugs to foods in any quantities, however small, is absolutely indefensible. Serious

injury—particularly to those who are specially susceptible to the action of these substances, or whose digestive and excretory organs are in any way impaired—must and does result. It must be borne in mind that these substances are added to a great number of foods, and that the contention of some defenders of the practice that a single small dose of boric acid or salicylic acid is harmless to healthy persons is beside the mark. Boric acid, for instance, is extensively used in all sorts of food. As already indicated, it is to be found in butter, cream, meat (including bacon and ham), fish, poultry, preserved meat and fish foods, and other articles, so that it is quite possible that in the course of a single day a consumer of these articles may take in a heavy dose of the drug.

Boric acid and compounds of boric acid and salicylic acid are drugs. Formaldehyde and sulphurous acid and sulphites are poisons. They are not foods in any sense. They are not natural constituents of milk, of butter, or of cream or meat, or of any other foods.

Boric acid and compounds of boric acid, salicylic acid, formaldehyde, and sulphurous acid, are added to foods for the purpose of arresting the progress of decomposition for a time, and, particularly as regards boric acid, for the purpose of masking or hiding the evidences of commencing or progressing decomposition. By the use of these preservatives it is possible to make a food in which decomposition has proceeded up to a certain point appear fresh to the ordinary observer, when it is, in reality, not fresh; and a vendor may thus be able to "palm off" stale or turning foods as fresh and wholesome foods.

The use of chemical preservatives is not necessary "for the production or preparation of foods as articles of commerce." Proper preparation, refrigeration properly applied, and cold storage are the methods which should be adopted for the preservation of foods for such periods as may be regarded as legitimate.

The practice of adding drugs or chemicals to foods is adopted by certain manufacturers and vendors largely for the purpose of avoiding the expense attaching to the provision of proper appliances and of adequate assistance to ensure cleanliness and reasonable preservation without the admixture of such drugs and chemicals. To allow the use of the latter is to encourage the employment of dirty and dangerous methods.

The addition of drugs and chemicals to foods is not excusable on the plea that, by this course, preservation, or *apparent* preservation, is obtainable for a longer time than when such drugs are not used. The keeping of articles of food for lengthy periods before use by endeavouring to prolong their "lives" beyond the natural limits with the aid of drugs is highly objectionable, and is necessarily always attended with danger to the consumer owing to the possible and, in fact, probable development and production of poisonous substances of a virulent character in the food by lengthy keeping.

On scientific, and particularly on chemical, grounds, and quite apart from the medical aspects of the subject, the presence of chemical preservatives in foods, in amounts sufficient to exert their specific "preservative" or "antifermentative" action on such foods, must, of necessity, interfere detrimentally with the processes of natural digestion of such foods, and, in so far as the "preservative" or "antifermentative" effects can be exerted by the drug present, so far are the chemical processes of digestion inhibited, retarded, or otherwise injuriously affected.

The adulteration of preserved green vegetables —such as peas, French beans and spinach—with sulphate of copper is a particularly abominable practice. The salts of copper are virulent poisons and many persons are specially susceptible to their effects. It is extraordinary that there are people to be found—some of whom ought to know better, and some of whom must know better—who endeavour to excuse this proceeding. It is commonly contended on behalf of the defence in cases of prosecution for the offence in question, as well as in cases of prosecution for the admixture of chemical preservatives with articles of food, that there is not adequate evidence to show that consumers have suffered definite injury to health by the ingestion of the "doctored" products. Without the actual exhibition of "awful examples" in court it is, of course, extremely difficult to prove injury of this kind by the production of specific cases. Surely the introduction into a food of some substance the physiological effects of which— apart from its effect on the food itself—may, in the opinion of some few people, be doubtful, is bad enough, but when we come to the introduction of known poisons into food the fact that there are some persons to be found who will try to excuse such a practice is somewhat startling. I may mention that no less than three cases of violent copper poisoning, unquestionably due to the ingestion of preserved

peas containing sulphate of copper, have come under my personal observation during the past few years. Another statement commonly made on behalf of the defence in cases of sulphate of copper adulteration is that the copper salt is added for the purpose of "preserving" the natural colour of the vegetable. As a piece of barefaced impudence this statement is certainly worthy of admiration. As a matter of fact the colour obtained is not the "preserved" colour of the vegetable, but is a false colour due to the presence of the copper salt and is the colour of a compound of copper.

I have no intention of entering at length into the great beer question. It will, I think, be sufficient to point out that the innocent "man in the street" is still under the erroneous impression that when he buys beer he is necessarily buying a liquid prepared from barley-malt, hops, and water. The beers produced by some brewers still conform to this requirement, but the permission given by a paternal Government to introduce what is known as the "free mash-tun" has resulted in the use of enormous quantities of sugars and of "substitutes" for barley-malt—a course of procedure which is stated by some of the representatives of the brewing industry and by some of their distinguished scientific advisers to have resulted in great advantage to the public. One of the advantages conferred on the public by the "freedom" alluded to was the extensive outbreak of arsenical poisoning which occurred a few years ago, mainly in the North of England and in the Midlands. Starch-glucose is a saccharine substance obtained by the action of sulphuric acid on any starchy material; the mineral known as pyrites—which contains arsenic—is used as a source of sulphur in the manufacture of sulphuric acid. If the sulphuric acid is not properly purified it is liable to contain substantial proportions of arsenic; arsenical starch-glucose, prepared by the use of arsenical sulphuric acid, was used, no doubt quite innocently so far as knowledge of the presence of arsenic was concerned, in the manufacture of certain beers, with the result that the drinkers of the beers developed the symptoms of arsenical poisoning, and in addition to many cases of illness and recovery, a number of lives were lost. The story is pretty and instructive, and in connection with that story it is advisable to bear in mind that starch-glucose is extensively used in the preparation of several other articles of food. I do not allege that the starch-glucose so used is arsenical. I merely point out the risk attaching to the use of this material without the absolute certainty that it is free from arsenic. I have only to add that starch-glucose—of course, not necessarily arsenical—is extensively used in the manufacture of certain kinds of confectionery, in the manufacture of certain liqueurs, and as an adulterant in "golden syrup."

Not very long ago it rather suddenly struck various people, both here and abroad, that when a purchaser asks for brandy he is entitled to receive a spirit distilled from fermented grape-juice or wine—distilled in a particular way and by the use of a particular form of apparatus. Inasmuch as genuine brandy has been made for centuries in this manner, and as its peculiar characters and its remarkable medicinal value, in cases where its administration is required, depend on the fact that it is so produced, it became necessary to ascertain whether, by analytical means, brandy properly derived from wine, and therefore genuine, could be distinguished from the factitious article consisting of "plain" or "silent" spirit, coloured and flavoured to resemble true brandy. Within certain limits this was found to be possible—not in all cases, but in many—with the result that several prosecutions for the sale of factitious brandy as "brandy" were instituted by various local authorities. The matter is plain enough—like the spirit used—but strange to say, some distinguished scientific experts of my acquaintance have managed to persuade themselves that *any* alcohol, in whatever way and from whatever raw materials it may have been produced, coloured and flavoured in imitation of real brandy, is to be regarded as "genuine" brandy. By what processes of reasoning my learned friends have managed to arrive at this conclusion I have been unable to discover. I can only say that, in my opinion, their contention is wholly indefensible and ridiculous. In spite of the prosecutions and of the convictions obtained, factitious brandies still masquerade on the market as genuine brandies, to the general detriment of the public and to the grievous injury of some whose chances of "turning the corner" in the peril of sickness may depend on the timely administration of the special stimulant in question.

As already stated, the adulterator is ever with us, and the appearance of new forms of adulteration in itself affords proof of the truth of this statement. A few years ago this country received large consignments of flour from America, such flour being adulterated with

from 5 to 10 or 15 per cent. of maize. Where the profit came in I do not know, but there can be no question that if there was no profit in the operation it would not have been carried out. Very recently a process for bleaching wheat flour has been introduced, which essentially consists in exposing the flour to the action of the oxides of nitrogen commonly known as "nitrous fumes." This process, to which the descriptions "electrical treatment" or "ozonised air treatment" have been imaginatively applied, injuriously affects one of the constituents of flour—the gluten—and has been shown to result in leaving undesirable impurities in the shape of nitrates and nitrites in the flour, and even in the bread made from it; while the effect produced on the gluten must unquestionably diminish the nutritive value of the bread. Another highly objectionable form of adulteration as regards wheat flour, which, so far as I know, has only quite recently been introduced, consists in the addition of acid phosphate of lime. This substance is produced from bones, and the process employed in producing it is anything but æsthetic. Here, again, in view of the methods which must necessarily be used, there is grave danger of arsenical contamination, and, in point of fact, this form of adulteration, which is stated to make the flour "go farther" in the production of bread, amounts to the introduction into bread of objectionable extraneous mineral matter of a possibly dangerous type.

I do not propose to enter into a consideration of the subject of "Standard Bread," to which the *Daily Mail* is now so effectively calling public attention. This matter is, in reality, outside the scope of my paper, and I merely confine myself to the statement of my opinion that the system of making bread from flours produced by milling processes which result in the removal of much of the valuable nutritive matter contained by the whole-wheat grain, is a system which has probably been the cause of much injury to the people, which can only be the cause of further injury if its application is persisted in, and which must be condemned accordingly.

There are many other facts and many other considerations which might properly be mentioned in a paper of this kind, but I know that any attempt to set them out would lead me too far. The fallacious and misleading statements which are commonly put forward for the purpose of defending or condoning various forms of adulteration are legion, and I should like to dissect them all and to expose their true nature to the public gaze. One fallacy I will allude to before concluding. This is the fallacy, industriously circulated by certain persons, that the annual reports of the Local Government Board on the working of the Food Acts may be taken to indicate a substantial yearly diminution in adulteration and a general improvement in commercial morality. The reports in question do not justify that conclusion. So long as in many boroughs and counties the Food Acts are dead letters, or are administered by authorities some of whose influential members, for reasons best known to themselves, approve of, and advocate a policy of, "*laissez-faire*," no accurate conclusions as to the extent to which adulteration prevails can be drawn from the official reports in question. The Board can only report on the information it receives. Our food laws—such as they are—have undoubtedly produced, and are still producing, very beneficial effects. But those laws are cumbrous, unwieldy, unnecessarily complicated, and exceedingly difficult to administer effectively. It is necessary that they should be recast into one strong and comprehensive law, framed in the light of all the scientific, legal, technical, and commercial knowledge and experience that may be available, comprising those provisions of the existing Acts which have been found to be beneficial to the public, and such new provisions as may be necessary to secure a vigorous, uniform, and effective administration; as well as the adequate protection and, I may add, the adequate remuneration of the officials whose duty it is to carry out the requirements of the law. The one central principle upon which all such laws must be founded is the main principle of the Act of 1875—that the purchaser shall receive the article which he has demanded, or which he must be presumed to have demanded. Although, having regard to the low standards and limits which must, perforce, be adopted, repressive legislation can never ensure the universal supply of foods of high quality to the public; although, in fact, repressive legislation, while tending to prevent the more serious forms of adulteration, must, of necessity, result in many cases in legitimatising the supply of inferior products, a law, framed with the central principle referred to constantly in view and devoid of the various loopholes and back doors for the escape of offenders which are the blots on the existing Acts, must be productive of enormous advantage to the people at large as well as to the honest manufacturer and trader.

DISCUSSION.

The CHAIRMAN thought all present would be agreed upon the importance of the subject that had been so ably dealt with in the paper, and impressed with the masterly way in which that subject had been presented to them. The lecturer appeared to have discovered that adulteration of some sort and in some degree had been common to all ages, and that in that respect the present generation were merely repeating history. Colonel Cassal had rightly shown that wherever and whenever adulteration had been committed, injury to the people had followed that departure from strict commercial morality. He (the Chairman) had the honour to represent a certain small area in London—but he thought he could claim, although small, important—where a leading part had always been taken in the movement of resisting the adulteration of the people's food. The Corporation of London, which he especially represented, had throughout their history taken an active part in enforcing the laws of the land in the protection of the people; and they had been associated with a number of City Companies, or Trade Guilds, which for centuries had found their chief employment in maintaining in the interests of the people good workmanship and pure materials—a combination which produced the article a purchaser expected to receive when he made a demand for it, or, in the words of the Act quoted by Colonel Cassal, "must be presumed to require." Those old City Companies, such as the Bakers, the Goldsmiths, and the Vintners, to which reference had been made in the paper, had laboured century after century, no doubt not entirely without regard to their own individual interests, but largely in the protection of the public against the fraudulent dealer. For instance, he remembered that the butchers had a very effective by-law to enforce punishment upon those who persisted in disregarding their moral responsibilities. If a butcher was discovered selling impure or putrid or diseased meat, the joints complained of were taken before a predecessor of his (the Chairman's) and if found to be defective, condemned. The man was then taken away to the pillory, and with him the defective meat. After he had been secured in the pillory the meat was placed under his nose and set on fire, so that the man should have the leisure of his enforced idleness to contemplate the wickedness of his act, and be at liberty to inhale the evidences of his villainy in selling what was impure and unworthy of consumption. He merely mentioned that to show how the little community he had the honour to represent had always been alive to the importance of the subject so admirably dealt with by the paper. The lecturer had spoken of the early adulteration of gold and silver. There again, if a person wanted to be quite certain that he was buying gold and silver, he at once looked for the stamp known as the hall-mark, which hall-mark was impressed by the Goldsmiths' Company—a Company that had been formed in the twelfth century to insist upon dealers in gold and silver giving to the purchaser of their goods the article for which he asked and the article for which he paid. Colonel Cassal also spoke of wines and spirits. Personally, although he did not put it forth as a matter that should receive legal commendation, he always thought wines and spirits, if adulterated with a no more injurious article than water, were rendered the more healthy by the greater adulteration! But that was merely a personal eccentricity of his own. He had simply mentioned one or two matters to indicate that the old City had long taken an interest in the subject under discussion, and the policy of the Corporation was to pursue a similar course in the future. The Corporation kept its inspectors, not in their offices, but going about all day long into shops in the City of London—into coffee and milk-shops as well as into wine and beer-shops, where, by making purchases through agents supposed to have no official standing in the City, they were able to test from time to time whether the citizens of London really got what they paid for and what they were entitled to receive. The Corporation's inspectors were even making inspection in regard to slices of bread and butter, so that the poorest of the poor should not be defrauded in the very food upon which their life and good health depended.

Mr. CHARLES S. GOLDMAN, M.P. (Chairman of the National Society for the Prevention of Adulteration), said all who had heard the very searching and instructive paper would agree that too much attention could not be bestowed on the question of food supplies, and above all on the purity of food in order to secure, as far as it was possible, immunity from the frauds which beset the population. Colonel Cassal was one of the most formidable forces against the sophistries and wiles of those who were committing acts of adulteration of foods, but at the same time both his friends and his opponents had to acknowledge that one of his chief characteristics was a desire for fair play towards all. Turning to the question of adulteration, he (the speaker) thought it was unfair to assume that because distressing symptoms did not manifest themselves immediately on the ingestion of either drugged or adulterated food, or food of an unwholesome character, the victim suffered no wrong. There were many records of human suffering as the result of adulteration, and none worse than in the case of infants. In spite of all the improvements in hygiene and preventive medicine introduced by Lord Lister and others, there was an alarming and increasing rate of infant mortality in this country which must be largely ascribed, as far as could be judged, to the primary conditions of infant life. That being the case, it was most necessary that the milk supply of this country should be carefully watched, and it should be seen that infants were given wholesome food. The question of adulteration, so intricate in its character, could, in his opinion, only be dealt with on

a large scale. It would be an insult to manufacturers to suppose that they were not sensible of the existence of the frauds that were being committed, and that they were not as anxious as anybody to detect those who were committing such frauds. What was necessary at the present moment, in order to prevent much of the dissipation of energy that was going on, was to try to organise the action of the two sections—the trades and the people. Colonel Cassal had already mentioned a Court of Reference, and he (the speaker) thought that was no impossible solution of the whole difficulty. He would venture to suggest that three panels might be formed, one panel consisting of the organised societies dealing with the particular question, one panel consisting of the manufacturers, and one panel consisting of neutrals, all trying to arrive at certain standards by which the food supplies of this country should be acknowledged and recognised. He thought if such standards were laid down, it would be found that the trades were ready to respond to such formulæ, and automatically would form a boycott against those who were unwilling to conform to the findings of the Court of Reference.

Mr. F. J. Lloyd said, as an analyst in the City of London for thirty years, he had had an opportunity of learning something about the adulteration which was taking place, not only in articles of food, but, he was sorry to say, in a great many other articles which were sold in this country. He was also Consulting Chemist to the British Dairy Farmers' Association, and therefore had had an opportunity of looking at some of the problems of adulteration from the point of view of the producer and manufacturer of articles of dairy produce which were so frequently sampled under the Sale of Food and Drugs Act, and which were so often the cause of litigation. He ventured to think it was very necessary to consider both sides of the question, especially with regard to the presence of preservatives in food. It must be remembered that in the enormous City of London, supplies of food were obtained from very great distances, and had to be produced many hours before they could be delivered and consumed, and it was a very great problem which the medical profession and the analyst and the public had to consider, as to whether it would be better to preserve that food to a certain extent from decay or to have it delivered in an incipient state of decay which perhaps it was not possible to estimate or to understand. He thought himself there would be a far larger amount of ptomaine poisoning if the use of preservatives of every description was totally prohibited. On the other hand, he protested against the illegitimate or unnecessary use of preservatives, and against the use of any article which was undoubtedly injurious to health, but in his opinion a happy medium was required; extremes should be avoided. He was also on the Committee for the Prevention of Fraud, appointed by the Chambers of Agriculture, which committee had to consider the question of adulteration, not only as affecting food but as affecting a great many other articles bought and sold in this country, and they had arrived at the conclusion, and had passed a very strong resolution—which had been universally supported by all the Chambers of Agriculture in the country—calling upon the Government to appoint a Court of Reference, as to which Colonel Cassal had so strongly spoken. He (the speaker) believed it was essential that the Government should appoint such a Court of Reference to lay down standards which on the one hand would enable the public analyst and the analyst generally to carry out his work with more certainty, and on the other hand would protect the consumer and the producer of the articles which were sold in this country. There was another point upon which he thought himself compelled to touch. It was, he thought, the expression of extremist views—especially by the reader of the paper and the medical profession—which had done a great deal to prevent, rather than to facilitate, the progress which everyone desired.

On the motion of the Chairman, a hearty vote of thanks was accorded to Colonel Cassal for his paper.

Colonel Cassal, in reply, said he did not think it was necessary to take up any time, as no questions had been put to him. With regard to his friend, Mr. Lloyd, he could have dealt with him at length if it had been necessary, but he did not think it was. Mr. Lloyd advocated a mild form of procedure and he (Colonel Cassal) did not: but on the main point, the establishment of a Court of Reference, they were agreed.

Mr. Waldorf Astor, M.P., had the greatest pleasure in conveying the thanks of all present to the Lord Mayor for presiding over the meeting. The audience were very grateful for his presence and the interest that he took in the movement for improving what he (the speaker) might describe as that most important national asset—physical welfare. Whether the society to which the lecturer belonged confined its efforts purely to protecting the public from adulterated and injurious foods, or whether they added education in food values, it was quite evident that the improvement of the physique and the digestion of the country would ultimately increase the happiness of the people. It was not necessary to have lived surrounded by hungry children or in contact with the typical choleric dyspeptic retired colonel of the novelist to know that good nutrition and good digestion meant increased happiness. The Chairman had referred to what he modestly described as a personal eccentricity; he might have told the audience that he had succeeded in doing what was exceedingly difficult in the present day, namely, establish a record —for

he was the first total abstainer to occupy the distinguished position of Lord Mayor of London. The position which alcohol in moderate quantities was to hold in regard to medicine had not yet been fixed and decided upon by men of science, but, whether the principles of the Chairman were agreed with or not, everybody had to admire one who had set out with an ideal and who, by abstinence, strength of character, and strength of purpose, had consistently carried out to the best of his ability that ideal.

Sir JOHN LAMB, on behalf of the Council of the Society of Arts, also welcomed the Lord Mayor and thanked him for his presence on this occasion. They knew how many engagements he had, and how difficult it was for him to fulfil them all.

The CHAIRMAN, in reply, said it had been a great pleasure to him not only to hear the able paper, but to be allowed to come into that hall and associate himself for the first time in his life with the Society, the records of which he had followed with much interest and instruction for many years. He was exceedingly pleased to find himself in a temple which, in his mind, he had always classed as classic ground. The Society had a long and illustrious history, and he could only hope that there remained for it in the future a part as distinguished, as honourable, and as instructive as its great past.

ARTS AND CRAFTS.

Wall-papers and Printed Cottons.—The new designs for wall-papers and printed cottons seem to be making their appearance rather earlier than usual this year. The most noticeable thing about the cretonnes is the number of patterns which are directly founded on old crewel embroidery. It seems to be essential that the more important patterns should look like something else rather than like printing. If they do not imitate needlework, they must at least do their best to simulate weaving. The one great exception to this rule is in the case of the Early Victorian designs of a so-called "naturalistic" type, which certainly have the merit of not pretending to be anything but what they are—ugly as they may be. An increasing number of wall-papers are produced on a black ground—recalling the period when an English version of Eastern, and especially Chinese, work was all the rage. Some of the designs on this sombre ground are, however, more nearly akin to seventeenth-century English needlework than to Oriental patterns. Again, the colouring of a good many of the wall-papers suggests the rather dumb tones of a certain kind of tapestry hanging rather than printed paper. The empty, open designs of a few years ago are a thing of the past, the once popular stripe has modestly retired into the background, and the sprig and spot patterns have vanished, except in cases where they reappear on the background of a well-covered all-over pattern of a neutral tint which, though it is sometimes quite elaborate, does little more in the distance than form a sort of broken colour effect. It is the fashion for wall-papers as well as printed cottons to pretend to be something other than they really are. Plain lining papers are, of course, still being used, often finished off, when they are hung, with a heavily-patterned frieze—but there are an increasing number of papers on the market which are meant to look like various other materials; some of them, evidently intended to be arranged in panels, are even got up to represent leather. There is little that is strikingly new in design; in fact, the prevailing fashion neither demands nor welcomes anything to which the salesman cannot, by no matter how great a stretch of imagination, attach the name of some well-known period. What is remarkable is the wealth of pattern which is being used both in wall-papers and chintzes. Whereas a couple of years ago no one seemed to want pattern at all, to-day the cry is for as much as can possibly be crowded into the space. The result at present, though there are a few good designs about, can hardly be said to be wholly satisfactory, but it is to be hoped that the fact that repeating pattern is in such demand will encourage designers to work with greater zeal, and will recall to the student, who has almost ceased to look upon design as a possible calling, the fact that there is such a thing as the art and craft of pattern design.

Art and Trade.—The word "trade" has so often an evil sound in the ears of those interested in art and craftsmanship, that the announcement that this year's spring exhibition at the Whitechapel Art Gallery was to consist entirely of work from trade schools belonging to, or subsidised by, the London County Council, has probably made many people think that, from the point of view of art, it would be a negligible quantity. But this is very far from being the true state of the case, and the show this year includes very nearly, if not quite, as much art work as it has done in previous years, when the work came from the art and technical schools as a whole. This is probably due, in part, to the fact that in the London schools of art design for manufacturing processes is very often shelved, looked down upon, or practically ignored. It is interesting, as well as encouraging, to see that in the trade schools the teaching of art seems in very many cases to go, of necessity, hand in hand with the proper teaching of a trade. The art will probably flourish all the more healthily from the fact that the student looks upon it as part of the necessary working equipment for his trade, and has not much temptation to consider his immature efforts at design or adaptation in the light of artistic achievements. Perhaps if, in the past, the young designer for manufacturing processes had been encouraged at school to take up

something more like this attitude towards his work, we should now have, not only more competent general designers working on their own account, but also more artistically trained trade designers and fewer unemployed—it would hardly be kind to say unemployable—art students.

Art Work in the London Trade Schools.—At Whitechapel there is, perhaps, rather a larger show of artistic work from the girls' trade schools than from the boys'. One wonders whether this may mean that there are fewer boys than girls taking advantage of the day technical schools. If that were the case it would not be surprising, as it appears that, while the course in the girls' schools is supposed to fit the students to go out as, at least, improvers, that in the boys' schools is, as a rule, only intended to lead up to apprenticeship. (Book production and wood-carving are, however, exceptions to this rule, and there may be some others.) This being the case, it must sometimes be difficult to convince parents that it is wise to let their boys begin their apprenticeship when they are between sixteen and eighteen years of age, even when they can afford to take such a course. If we turn to the artistic exhibits from the boys' schools we find that they consist of woodwork, metalwork, and the arts and crafts connected with book production. The largest exhibit comes from the Shoreditch Technical School, and shows a very high level of accomplishment. The boys in the woodwork class are evidently taught the intelligent and tasteful use of simple marquetry patterns, and shown how to make the best artistic use of the grain of the various woods. Among the exhibits are a large, very well-proportioned bookcase (it is a pity that the student did not choose a rather more elegant shape for his patch of colour in the lower doors), a pretty little satinwood table with a dainty design in inlaid veneers round the edge, and some good simple chairs. The metalwork, mainly fire-irons, hinges, and the like, is very vigorous, and shows good appreciation by the students of the quality of the materials with which they are dealing. There are some workmanlike drawings, too; but the ideal of design shown by the sheet of drawings adapted from the horse-chestnut is not very laudable. The articulation of the stem is, of course, an important point for the designer to note and to use, but it must be observed and used intelligently, and not in a purely mechanical fashion. The School of Art Wood-carving, at South Kensington, sends a couple of boards, to which are affixed a fair number of specimens of the work done by the day scholars. The exhibits, which include one panel to which a prize was awarded at the National Competition, show not only a creditable amount of artistic appreciation, but also a high standard of technical skill. There is a case of silversmiths' work, including one or two very pretty little bits of *repoussé* work, from the Central School, and another case of work connected with book production. Many of the exhibits in this division are very creditable and show a good sense of proportion and spacing, though some of the tooled lettering might with advantage have been omitted from the collection.

The artistic work of the girls' schools resolves itself almost entirely into needlework of one sort and another, and consists mainly of embroidery and braiding of various kinds, done in connection with upholstery, tailoring and dressmaking. The best artistic work in upholstery comes from Shoreditch, where the girls seem to be taught to make their work tell to the best possible advantage, and to have some idea of what is pleasing in colour. The brown cushions, modestly braided with a variegated braid, are admirable of their kind, and there is a cloth curtain, ornamented with a simple pattern—partly cut out with a background of silk showing through—which is very tasteful. The largest, and perhaps the most attractive show of embroidery comes from Woolwich, and includes, besides a very pretty collection of samplers, some interesting *appliqué* work and stitchery on soft leather, admirably adapted to the trimming of coats and skirts. The samplers are beautifully neat, and some of the stitchery on the dresses, etc., is very good, but the students sometimes go very wrong in their colour-schemes. They appear frequently to be aiming at something which would be quite good if it came off, but it so often seems to fail. The workmanship, also, is too exclusively of one type; it is a very dainty type, it is true, but it does not seem by any means to cover all the kinds of embroidery which would be useful to dressmakers and tailoresses. It is the kind of stitchery almost universally in favour in the Council's schools at the present moment, but it covers a comparatively small portion of the field of artistic needlework. The embroidery from the Borough Polytechnic makes a less striking show, but it appears to indicate a fairly comprehensive course of study, and one which should enable students to adapt themselves readily to different kinds of work. Some of the *appliqué* work for upholstery cannot be said to be satisfactory, artistically speaking, and the colour-schemes generally are rather dingy, but the samplers and other work executed in connection with the dressmaking and tailoring classes show a good range of stitches and methods, and an appreciation of how to use braiding and *appliqué* judiciously and with effect.

EMPIRE NOTES.

The Nigerian Tin Fields.—A book entitled "Nigeria and its Tin Fields" has just been published. It is an exceedingly interesting volume by Mr. Albert F. Calvert, and gives a glowing account of the mineral wealth of Northern Nigeria. Tin is not really a common metal, and is in growing demand for a variety of industrial purposes. The existing fields from which supplies are drawn are very limited. The county of Cornwall, the Dutch East Indies, Tasmania, the Malay Peninsula, and the Straits Settlements are responsible for most of

the world's supply. The author asserts that the province of Bauchi is enormously rich in alluvial tin deposits. The deposits cover so wide an area that they are likely to yield large quantities of metal for many years to come. At the present time the price of tin is approaching £200 per ton, which shows that the supply is quite unequal to the demand. If, therefore, these tin-fields be all that is claimed for them they will prove a welcome boon to British manufacturers.

Rhodesian Prospects.—The report of the British South Africa Company for the year ending March 31st, 1910, is just to hand, and shows in detail the rapid progress being made in Rhodesia. This year is the most successful in the history of the company. The report states that substantial progress is being made, especially in the farming industry of Southern Rhodesia. A number of changes in the methods of inducing settlement have taken place, and concentrated efforts are being made to take advantage of the good prospects which the country offers for farmers and stock breeders. The local markets are being widely extended. This is due in a large measure to the continued growth of the mining industry. Many new districts have been opened up in Southern Rhodesia, and there has been an increase in the number of country townships. General business appears to be broadening, and the population of the principal towns is outgrowing the available accommodation. The building trades are flourishing. It is proposed to concentrate land settlement during the coming year in the districts of Lomagundi, Hartley, and Mangwendi in Mashonaland; and Gwelo (including Charter), Belingwe, Wankie, and possibly Mafungabusi in Matabeleland. An encouraging feature of the year has been the increased number of applications received for land suitable for ranching. Considerable areas have also been acquired by experienced stock farmers possessed of ample capital for their development, and the selection of land by the Lemco and Oxo companies has practically been completed. The tobacco industry continues to expand. During the season 1909 to 1910 the area under cultivation was estimated to be 700 acres. This area will be largely increased during the present season, provided that a sufficiency of native labour is forthcoming. The high quality of the leaf is maintained, and the last season's crop would have shown a considerable improvement over the previous year but for an untimely drought in February, followed by heavy rains, which resulted in there being a second crop bearing a coarser and rougher leaf. The prospects for the ensuing year are excellent, the planting season being one of the best on record. It is understood that the question of manufacturing tobacco is now under consideration, and there is every reason to believe that a successful undertaking awaits development.

New Departures in Shipping.—There appears to be no limit to the progress of the British mercantile marine, as each succeeding year shows an appreciable advance on the previous year's operations. The passenger traffic between the United Kingdom and Australia has increased considerably during the past ten months, and at present it is with difficulty that the requirements of third-class passengers are met. There is urgent need for a new service between London and the southern continent. The shipping companies are doing their utmost to cope with the traffic, and to this end the P. & O. Branch Service (formerly Lund's Blue Anchor Line) have converted the accommodation on all their vessels into third-class cabins, thus carrying one class only. This is a great advantage to third-class passengers, as thereby they have the run of the entire ship and are not restricted to the steerage quarter. The Liverpool White Star Company inaugurated this arrangement many years ago and it proved a great success. Messrs. Geo. Thompson & Co., of the Aberdeen line, have just despatched to Australia the latest addition to their fleet, the T.S.S. "Themistocles." She is a splendid twin-screw steamer of 11,400 tons register, and has accommodation for first and third-class passengers. A novelty in cabin structure is introduced in this steamer, one deck being entirely devoted to single-berth cabins, which can be made inter-communicable if desired. A full cargo for homeward voyages is readily obtainable at the Australian ports. The Imperial Steamship Company has received its charter from the Canadian Government, and it proposes to give effect to an "all-red" line between this country and the Antipodes. A service will be established by means of "ferries" from England and Scotland to Ireland, thence *via* Blacksod Bay to Halifax, and from Vancouver to Australia and New Zealand. The vessels are to be able to cross the Atlantic in three and a half days, and a speed of twenty-five knots an hour will be run on the Pacific.

Canada's Emigration Restrictions.—Mr. W. D. Scott, Superintendent of Immigration for Canada, giving evidence before the Dominion House of Commons on Colonisation and Agriculture, pointed out that the immigration restrictive regulations had resulted in a greater influx of people and a marked improvement in the class of settler. He stated that two hundred officials employed on the international boundary, during 1910, refused entry to 14,131 settlers from the United States who were considered by them to be undesirable. Only 252 British settlers had been refused entry during the same period. Compared with the large number of persons who emigrated from the British Isles to the Dominion last year, and having regard to the restrictive measures in force, these figures are remarkable.

Tariff Revenue in Australia.—In a leading article, the *Melbourne Age* expresses extreme dissatisfaction at the increase in revenue from the customs duties. It says: "The duties on goods

which ought to be made in Australia, and yet owing to deficient protection are still imported, continue to increase at a remarkable rate." A number of instances are cited, the most important being apparel and all kinds of soft goods, which, during the ten months, January to October, 1909, were imported into the Commonwealth, to the value of £10,482,793, and in 1910 to the value of £12,353,874. Other manufactured articles which show a big increase in imports are boots and shoes —1909, £222,210, and in 1910, £304,818. The newspaper considers that the tariff should be amended in an upward direction in order to ensure many of the articles named being manufactured in Australia.

Ex-Service Men and Emigration.—A meeting was held early last month at the Royal United Service Institution, Whitehall, having for its object the consideration of the question of ex-service men and the openings for them in our over-sea dominions. The chairman, Field-Marshal Lord Roberts, referred to the need of many of these men who had served their country at home and abroad and who, on re-entering civil life, found it difficult if not impossible to secure regular employment. For such men he thought something should be done to enable them to obtain work overseas within the Empire. He did not advocate emigration for the men who could find suitable employment at home, but, knowing as he did many cases of want and distress on the part of men well fitted for colonial life, he strongly favoured the work which had been begun by the Naval and Military Emigration League, under whose auspices the meeting was held. Some interesting information was given in regard to the work of this league by various speakers at the meeting, one of whom, the Rev. H. C. Martin, the secretary of the Royal Army Temperance Association, Simla, spoke of the opportunities which such an organisation would have in India, in the interests of soldiers who were leaving the Service and who desired to settle in Australia, Canada, or South Africa. Other speakers, among whom were Field-Marshal Lord Grenfell and Mr. Walter Hazell, chairman of the Emigration Committee of the Central Unemployed Body, spoke of the necessity of making some adequate provision for men on leaving the colours, as well as for those who, having left, could not find their niche in this country, but for whom opportunities of profitable employment could be found in the colonies. It was stated also that it would materially aid the work of enlistment, if it were known that openings could be found for soldiers, when their term of service ended, in other parts of the Empire.

OBITUARY.

The Hon. George Payne, J.P.—Intimation has been received of the death from pneumonia of Mr. George Payne, of Durban, while on a visit to this country in October last. Mr. Payne, who was in his sixty-seventh year, had lived in South Africa for nearly half a century. He started in business in Maritzburg, but in 1870 he entered into partnership with his brother in Durban, where they became one of the largest firms of wholesale and retail outfitters in the Colony. Mr. Payne took a deep interest in municipal and political work. He was thrice mayor of Durban, and for a short period Treasurer of the Colony of Natal. He joined the Royal Society of Arts in 1902.

GENERAL NOTE.

Insect and Fungus Pests.—According to Dr. R. Stewart MacDougall, of Edinburgh University, the harm done by insects and fungi, and the toll levied by them on various crops, can scarcely be exaggerated. A fungus wiped out coffee plantations in Ceylon. The Nun moth several years ago cost the Government of Bavaria, in destruction of spruce forest, £100,000. The money loss on account of insects and fungi in the United States represents in a year a sum of money greater than the cost of the year's upkeep of the American Army and Navy, and over a ten years' period the amount of timber killed and reduced in value in America by insects represents an average loss of 62,500,000 dollars a year. Fungi are plants which, in addition to having no distinct root, stem and leaf, but really just a mass of branching threads for their vegetative structure, contain no chlorophyll. By virtue of the possession of chlorophyll (the green colouring matter of the plant) other plants are capable of leading an independent existence. No fungus is independent. In order to live, therefore, a fungus must strike up a partnership with an independent plant, as is the case with lichens, or must prey on live animals, as with the ringworm fungus, or must prey on live plants, as the fungus causing larch disease, or must live saprophytically on breaking-down organic matter, like the mushroom and some moulds and rots. Both insects and fungi pass through a definite life-cycle, and, as aids in the solution of their life-struggle, have various ways of tiding themselves over untoward conditions, and of spreading themselves when the conditions are favourable. A knowledge of the different life histories is necessary before treatment against their attacks can be rational and successful.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

March 22.—Arthur Charles Davis, F.C.S., Assoc.Inst.C.E., "The Manufacture of Portland Cement."

March 29.—George B. Heming, "Art Education in Jewellery and Goldsmithing and Allied Trades." Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., will preside.

APRIL 5.—HENRY L. HEATHCOTE, B.Sc., "Wheels, Ancient and Modern, and their Manufacture."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

APRIL 27.—SIR THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord AVEBURY, D.C.L., LL.D., F.R.S., will preside.

MAY 25.—W. R. H. MERK, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

APRIL 4.—Captain R. MUIRHEAD COLLINS, C.M.G., "Australia and her Resources."

MAY 9.—F. WILLIAMS TAYLOR, "Canada and Canadian Banking."

CANTOR LECTURES.

Monday Evenings, at 8 o'clock:—

Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

Syllabus.

LECTURE III.—MARCH 20.—"The Technical Applications of Electric Heating." The Manufacture of Graphite, Carborundum, Calcium Carbide, Quartz Glass, Aluminium, Ferro-Alloys, and Iron and Steel in Electric Furnaces—Electric Welding—Electric Furnaces for Metallurgical and Chemical Operations.

LECTURE IV.—MARCH 27.—"The Domestic Applications of Electric Heating." Electric Water Heating—Its Cost and Economy—Air Heating by Electric Radiators and Convectors—Electric Cooking—Various Systems and Types of Utensil critically discussed—The Advantages and Drawbacks in Comparison with other Methods of Culinary Heating.

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 20...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor J. A. Fleming, "Applications of Electric Heating." (Lecture III.)

Bibliographical, 20, Hanover-square, W., 5 p.m. Mr. H. Thomas, "The Bibliography of Amadis of Gaul."

Victoria Institute, 1, Adelphi-terrace House, W.C., 4.30 p.m. Dr. T. G. Pinches, "Professor Hilprecht's newly-discovered Deluge Fragment."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. A. M. Brice, "The Legal Duty of the Architect."

TUESDAY, MARCH 21...Statistical, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. Charles V. Sale, "Some Statistics of Japan."

Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Annual General Meeting. Professor L. T. Hobhouse, "Eugenics and Sociology."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. M. A. Stein, "Explorations of Ancient Desert Sites in Central Asia." (Lecture I.)

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. F. W. Hill, "Open Air Statues in London."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Philip Dawson's paper, "The Electrification of a portion of the Suburban System of the London, Brighton and South Coast Railway."

Zoological, Regent's-park, N.W., 8.30 p.m. 1. Mrs. E. W. Sexton, "On the Amphipod Genus *Leptocheirus*." 2. Messrs. J. Lewis Bonhote and F. W. Smalley, "On Colour and Colour-pattern Inheritance in Pigeons." 3. Dr. G. Stewardson Brady, "Notes on Marine Ostracoda from Madeira."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. T. J. Alldridge, "Sierra Leone and its Commercial Expansion."

WEDNESDAY, MARCH 22...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. A. C. Davis, "The Manufacture of Portland Cement."

Geological, Burlington House, W., 8 p.m.

United Service Institution, Whitehall, S.W., 3 p.m. Dr. T. Miller Maguire, "Improvised Armies in the XIXth Century: an Historical Analysis."

Royal Society of Literature, 20, Hanover-square, W., 5 p.m. Prince V. Bariatinsky, "The Misfortune of being too Clever." A Classical Russian Comedy by Alexander Griboyedoff.

Mining and Metallurgy, at the Institution of Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m.

College of Preceptors, Bloomsbury-square, W.C., 7.30 p.m. Discussion on "Vocational Education; or, The School as a Direct Preparation for the Work of Life," to be opened by Mr. Cloudesley Brereton.

THURSDAY, MARCH 23...Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Child Study, 90, Buckingham Palace-road, S.W., 6.30 p.m. Annual General Meeting. 7.30 p.m. Mr. W. H. Stuart Garnett, "The Educational Possibilities of the Boy Scout Movement."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "Giants and Pygmies." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. R. Humfrey, "Present Day Press Photography, with a Few Experiences."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Messrs. H. A. Ratcliff and A. E. Moore, "Electricity Meters with Notes on Meter Testing."

FRIDAY, MARCH 24...Royal Institution, Albemarle-street, W., 9 p.m. Sir David Gill, "The Sidereal Universe."

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7.30 p.m.

National Health Society, in the Theatre, Burlington-gardens, W., 5 p.m. (Lady Priestley Memorial Lecture.) Mr Stephen Paget, "Pasteur and his Work."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. James Swinburne, "The Uses of Chemistry in Engineering."

SATURDAY, MARCH 25...Municipal and County Engineers (Western District Meeting), Torquay, 11 a.m. Mr. H. A. Garrett, "Municipal Engineering Works, Torquay, carried on during the past seventeen years, viz.:—the Promenade Pier, Sewerage and Floods Prevention works, the Dolter Surface Contact System of Tramways (now being converted to the overhead system), the Refuse Destructor, Municipal Buildings and Pavilion."

Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Radiant Energy and Matter." (Lecture IV.)

Journal of the Royal Society of Arts.

No. 3,044. VOL. LIX.

FRIDAY, MARCH 24, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 27th, 8 p.m. (Cantor Lecture.) Professor J. A. FLEMING, M.A., D.Sc., F.R.S., "Applications of Electric Heating." (Lecture IV.)

WEDNESDAY, MARCH 29th, 8 p.m. (Ordinary Meeting.) GEORGE B. HEMING, "Art Education in the Jewelry, Goldsmithing and Allied Trades." Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., M.D., LL.D., will preside.

CANTOR LECTURE.

On Monday Evening, March 20th, Professor J. A. FLEMING, M.A., D.Sc., F.R.S., delivered the third lecture of his course on "Applications of Electric Heating."

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A Meeting of the Indian Section was held on Thursday, March 16th, 1911, the Right Hon. Lord NORTHCOTE, G.C.M.G., G.C.I.E., C.B., presiding.

The CHAIRMAN said it was a particular pleasure to him to have the honour to occupy the chair that afternoon, and to introduce Mr. Hill. For many years—in his capacity as Governor of Bombay—he had had the advantage of the invaluable services of Mr. Hill. To those amongst the audience who were personally acquainted with India, the author of the paper would need little or no introduction. He was a gentleman who had served with distinction in many parts of India, and who had had the good fortune to possess in no common degree the esteem and confidence of many of those ruling chiefs and leading natives of India, without whose confidence and good-will the task of governing India successfully would be infinitely more difficult.

The paper read was—

EDUCATION IN INDIA.

By CLAUDE HAMILTON ARCHER HILL, I.C.S., C.S.I., C.I.E.

I fear that the title of this paper may suggest that it is proposed to enter upon and discuss the whole problem of Indian education in all its aspects. Not only, however, would that be impossible in the space allotted, but I could lay no claim to special qualifications entitling me to attempt such a task. It is to one particular feature of the problem—one in regard to which an intimate and friendly acquaintance with many individual Indians, and with their views and feelings in the matter, is even of greater importance than an abstract knowledge of the educational system—that I venture to invite your attention. I refer to religious or moral training.

In his masterly treatise on "Indian Unrest," Mr. Valentine Chirol devotes no fewer than five chapters to the subject of education, and one of them solely to the question of religious instruction; and that may be taken to be the measure of the importance to India of the problem. It is possible that if, at the time when I was asked to name the subject of my paper, I had had access to the whole of Mr. Chirol's articles, and had realised how fully he had dealt with this matter, I might have refrained from this attempt to give prominence to it; but on reflection it has seemed to me that the political point of view from which, in Mr. Chirol's work, the subject was of necessity regarded, is not the only, or perhaps the most important, one, and that there may be advantage in examining our position in the matter rather from the ethical standpoint.

I propose, first of all, to give you, in the briefest possible outline, a sketch of the history of the connection of the Government of India

with the promotion of education in India, and of the direction in which their policy towards moral instruction was moulded; then to describe the attitude, as I understand it, of the Indian mind towards education and religion, and to lay before you certain considerations which seem to indicate that we should reconsider the rigidity of our policy of secularisation; and, finally, to make one or two suggestions as to the methods by which the change might be effected with the least difficulty and risk.

Up to the year 1813 the little that had been achieved in education in India upon modern lines was due almost entirely to missionary enterprise, and outside the sphere of missionary activity, and away from the larger centres, the instruction of youth was confined, speaking generally, to the teaching, here and there, of reading and writing and of the Hindu scriptures to some of the members of the priestly and clerical castes. Between the years 1823 and 1840, committees of public instruction, under various names, were established in Bengal, Madras and Bombay, and some progress was made by these bodies in establishing English and vernacular schools. Prior to 1839 a lively contest took place between the advocates of Oriental and Western education, which, through the influence of Lord Macaulay, resulted in the adoption of a system based on English principles. But the basis upon which the educational system of India still rests to-day is that outlined in the important despatch of the Court of Directors, dated July 19th, 1854, much of which I should like, if time permitted, to quote here. I must, however, confine myself to such brief extracts as have a direct bearing upon the restricted aspect of education with which this paper attempts to deal. After emphasising in paragraph 7 the decision arrived at by Lord Auckland's Government in 1839, "that the education which we desire to see extended in India is that which has for its object the diffusion of the improved arts, science, philosophy and literature of Europe; in short, of European knowledge," the Court of Directors proceeded to outline the organisation of separate departments of education in each Province, the establishment of universities at the Presidency towns, and of institutions for training teachers; the maintenance and establishment of colleges, high schools, middle schools and elementary schools, and the introduction of a system of grants-in-aid on a basis of perfect religious neutrality. The wording in regard to this last-named point is instructive and important. In paragraph 53 Sir Charles Wood wrote that "The system of grants-in-aid, which we propose to establish in India, will be based on an entire abstinence from interference with *the religious instruction conveyed in the schools assisted.*" At the same time, although, in dealing with the university examinations to be prescribed, it was stated (paragraph 28) that the "examination for degrees will not include any subjects connected with religious belief," and (paragraph 32) that there would be ample field, in connection with the teaching of the Oriental classics, "unconnected with any instruction in the tenets of the Hindu or Mohammedan religion," it is clear that the Court of Directors, when pressing for the establishment of schools all over India under local management, subject to Government inspection, contemplated that religious instruction *would* be imparted, and that such instruction would be no bar to the receipt of a grant-in-aid, provided that the school was otherwise conducted up to the requisite standard of efficiency.

As a matter of fact, the grant-in-aid system proved only a very qualified success owing to the apathy of the people, and a few years later it became necessary to consider the levy of a special rate on land to defray the cost of providing for elementary education.

As a result of the recommendations of the Education Commission of 1882, primary education was given an almost exclusive claim to local funds set apart for education, and the control over the expenditure and the management of the schools was given to local bodies, who, under more recent orders, are stringently required to allot a fair proportion of the cess to education, and the bulk of that sum to primary education. Many important matters were dealt with by the Educational Conference of 1901, and discussed in a comprehensive review of the progress of education, issued by Lord Curzon's Government in March, 1904, of which, for present purposes, the most important portions were those (paragraphs 25, 38, and 40) which affirmed the supreme importance of providing a properly-trained teaching staff, and dealt with certain tendencies unfavourable to discipline which had then come so prominently to notice. In respect of these it was observed that "in Government institutions the instruction is, and must continue to be, exclusively secular. In such cases the remedy for the evil tendencies . . . is to be sought not so much in any formal methods of

teaching conduct by means of moral text-books, or primers of personal ethics, as in the influence of carefully-selected and trained teachers."

The earliest efforts at imparting education to India having been due to missionary enterprise, it was natural that the Government, when they began to realise their responsibilities in the matter, should be especially careful to guard themselves against any suspicion of participating in a proselytising movement. Hence the repeated reassuring declarations of strict neutrality. It is, however, worth while strongly to emphasise the point that the Court of Directors fully contemplated that, in the elementary schools (which they hoped would find local support and only be aided by Government) religious instruction, according to local needs, *would* be arranged for; and that Sir Charles Wood's despatch only laid down that we should not interfere with that branch of education. Elementary education is now supported mainly by the local cess and administered by local bodies under Government supervision and inspection; and, in the strictest interpretation of the policy laid down in 1854, it is possible to hold that there is no bar to those local bodies arranging for regular religious or ethical instruction, unless it be the reiteration, in the orders I have quoted, of 1904, that "in Government institutions the instruction is, and must continue to be, exclusively secular." The village school, in the vast majority of cases, is technically a Government institution; but the local body administering it, at the cost of the local cess, may fairly be regarded as being in the position contemplated by the Court of Directors when laying down the policy of the grant-in-aid.

I may now turn to the attitude of the Indian mind towards this question, with a preliminary explanation in respect of the terms used. Besides Hindus, in countless castes and sects, the Indian peninsula is peopled by Mohammedans, Sikhs, Jains, Parsis, and so forth. But the Sikhs and Jains are racially Hindus, and so is a very large proportion of the Mohammedans, while the others are numerically small. What I shall have to say of the Hindu or Indian mind, therefore, applies, in essentials, to the mentality of many of the religious sects who do not, strictly, come within the category of the Hindus.

As has been well said in Chapter XX. of "Indian Unrest":—"In India . . . religion in some form or another . . . is the dominant force in the life, both of every individual and of every separate community to which the individual belongs. Religion is, in fact, the basic element of Indian life, and morality, apart from religion, is an almost impossible conception for all but an infinitesimal fraction of Western-educated Indians." Mr. Chirol's conclusion that, such being the case, any attempt to instil ethical notions into the mind of the Indian youth, independently of all religious teaching, could only result in failure, will be referred to later. The reason why religion plays such a fundamental part in India is not far to seek. Whether Manu was a Kshatriya who assumed the priestly office, or whether he was a Brahmin, the fact remains that the Code to which his name is attached represents the social ordinances of a people, or rather peoples, of very complex civilisation, devised and carried into effect over a period of many generations, but having, as their ultimate sanction, not the mandate of a temporal sovereign, but the force and rigidity of the divine will. In a community whose social laws were invariably framed by the hereditary priestly caste, it was perhaps natural to claim for them divine inspiration; and the result, which it is so difficult, and yet so important, for us to appreciate, is that the whole social system in India, which has persisted through so many centuries, rests upon a religious basis. That system, moreover, is prescribed in such detail, and has, for each item, such specific religious sanction, that there is no act or event of the ordinary day which has not a religious symbolism. "The fetching of water, the ablution, the preparation and consumption of food, the transaction of business, the setting forth upon a journey, the crossing the threshold of a house, each and every one of these daily functions is associated, more or less consciously, with the observance of some" ritual, or some recognition of or obeisance to the god-head. With the vast majority of the subject peoples plunged in darkest ignorance, the need for impressing upon them the divine nature of the social ordinances helped to give rise to the multiplication of the deities. The loftier conceptions of the higher Hinduism could not be expected to appeal to intelligences untrained. Hence, and partly, perhaps, as a counterblast to the purity of the democratic teachings of Gautama, were evolved the multitudinous, and so often degraded, symbols of the deity adapted to the concrete requirements of everyday life. Marred as much of the beauty of the higher Hinduism has been to suit the popular understanding, the fact remains that

the whole life of a Hindu, from ages before his present birth till countless ages after, is regarded as one eternal, foreordained association with the divine; as a cycle of births each connected with the last. It is thus that Hinduism is a universal pantheism, involving the eternal perpetuation of a social system rooted in the very essence of itself; and it is for the foregoing reasons that the social law, regarded less as a rule of conduct than as an emanation of the divine purpose of the Universe, has been and is so rigid and immutable. Ritual and ceremonial, ill-understood and ignorantly performed, perhaps, by the mass of the people, but yet helping to form a rule of life and conduct, were, therefore, part and parcel of the upbringing of the Hindu child. In cases where the child went to school, the parent assumed, with good reason, that such teaching as he received included, as an essential adjunct, the learning of some portions of the sacred books.

Now, as is well-known, a cardinal feature of the teachings of the Hindu sacred literature is the stress that is laid upon the respect due to a parent by his children, by the student to his *guru*, and by the subject to constituted authority; with the result that in no country in the world was the family tie so strong, or the instinct of deference to age and learning more pronounced. And it was into a community with such traditions of reliance upon authority that we introduced, with the most benevolent intentions, a system of Western education based on Western ideas, but bereft of the one element which entered into all the social relations of the people. The laudable efforts of Government officials resulted, after 1854, in a very great expansion of the school-going population; but, since the hoped-for scheme of grants-in-aid of schools indigenously established proved abortive, or at least met with only very qualified success, the schools newly established were, in the vast majority of cases, Government institutions which made no provision whatever for religious instruction. Parents, acquiescing in accordance with their traditions, permitted their sons to go to the Government schools and asked no questions; while it seems till recently never seriously to have occurred to the authorities that a radical change in the nature of the people would necessarily follow such a vital alteration in the methods of bringing up the youth of the country.

The change has occurred. Those who deplore it most are the older generation of Indian gentlemen. Hindu, Mohammedan and Parsi parents have told me of the deplorable change in the attitude of children to their parents, and have, many of them, urged that the Government should do something in modification of an educational system which they hold to be responsible for the result. Religion, or at all events ethics based upon religion, they now realise, must be an integral part of an Indian's education; and they ask that, if the difficulties in the way of the establishment by Government of denominational teaching are insuperable, facilities shall be given for imparting a moral training based, so far as may be, upon the ethics common to all the higher religions.

The problem confronting the British Government in India can, therefore, be considered under the following headings:—

Firstly.—Are we debarred, either by guarantees or by policy, or on account of the inherent difficulties in the path, from reconsidering the decision that we should countenance no religious teaching of any kind in educational institutions for which we are responsible?

Secondly.—If we are so debarred, is it possible to devise means whereby the lacuna in the upbringing of the youth of India can be partially made good?

In respect of the first question, regarded in the light of an ethical problem, much might be said. It could be contended that a policy of strict neutrality imposes on us the obligation to give equal opportunities and facilities to the religions of all the nationalities and races over which we hold sway; and it must be acknowledged that this is not the case at present. It could be, and has been, argued that, wherever the State intervenes and undertakes the responsibility of educating the peoples under its dominion, it is bound to provide instruction in the moral principles of the religions professed by those peoples; and a good case could be made to show that the banishment of such tuition from Indian schools, as a result of past policy, has been not neutrality but an unintentional failure to realise a moral obligation. Such guarantees as have been given—as, for example, that contained in Queen Victoria's proclamation of 1858—most certainly do not debar us from giving facilities, to those who desire it, for acquiring instruction in their own religions, and I do not think that the policy as outlined in 1854 can be interpreted as an absolute bar, though it may have been, by inadvertence, more stringently interpreted on subsequent occasions.

If, however, the suggestion I made earlier in this paper could be approved, namely, that

local bodies administering the elementary schools in their charge should be regarded as falling within the category of the aided schools contemplated by Sir Charles Wood, in respect of which, you will remember, the Governments in India were only directed to refrain from interference with the religious instruction therein conveyed, then the flank of the difficulty would be turned; and I believe there would remain no insuperable obstacle in the way of a great and much-needed reform. I should like to quote to you the words of a very eminent Brahmin, holding the highest official position in a Native State, and one enjoying universally the greatest respect and esteem. He addressed a letter to the press in India, about three years ago, urging that Government should leave primary and secondary education entirely to the people, for the reason, among others, that in a huge continent like India, the Government cannot inculcate the moral training and impart the religious knowledge so essential to Indian minds. "It is in primary schools," he wrote, "that the foundation of moral ideas is laid, and it is primarily the text-books of these schools which have to infuse in infant minds the ideal of a moral and virtuous life."

It will no doubt be said that, even if there be neither guarantee nor policy which absolutely debars us from modifying the system of education as hitherto applied, there are practical difficulties of an insuperable character in the way of any scheme of religious instruction under the ægis of the State. At a conference on this subject, held in Bombay at the instance of His Excellency Sir George Clarke in April, 1910, several speakers emphasised the difficulty incidental to the number and diversity of the races and religious creeds, even in one province. The difficulties may at once be admitted, but that they are not insuperable requires little demonstration. It is, of course, well known that the State of Mysore has incorporated in its curriculum a scheme of religious and moral training; but it is, perhaps, not equally widely known that a considerable number of aided schools and private institutions in British India and in Native State territories, have also adopted the text-books of the *Sanatan Dharma* series (published by the Hindu Central College at Benares), and have regular courses of instruction in them. Now there are Mohammedan pupils in the Mysore State, and non-Hindu pupils in the other institutions; but I have not heard of a single instance in which difficulty has arisen, or objection has been taken, on that account. And yet, that there is, *primâ facie*, room for such objection is manifest to anyone who will study the books of this series. While in themselves innocent enough, they are so essentially and exclusively Hindu and so peculiarly transcendental in their teaching, that they are open to criticism, not only at the hands of pupils professing other faiths, but on the ground that in the higher series they are less concerned in inculcating a high ethical standard of conduct than in instilling the principles of a philosophy peculiar to a certain and limited class of Brahminism. And yet these text-books have achieved a certain vogue, and their use is extending, while shorter adaptations of their doctrine are being prepared for local use by some more intelligent headmasters. I have laid, perhaps, undue stress upon these Benares publications, because they, and their adoption in a considerable number of schools, are an indication, first, of the possibility of giving religious instruction in India, and, secondly, of the awakening of the people of India—especially the older generation—to the absolute necessity of devising means for affording definite and systematic training for their children in the ethics of their religion.

Thus far it has been suggested, on a consideration of the history pertaining to our control of Indian education, that it has not been our deliberate policy to oust religious instruction from the schools of India, but that the practice has been the result of an excessive scruple, coupled with the apathy of the people themselves, who failed adequately to support and foster elementary education. The published views of an eminent Indian (Brahmin) authority have been cited in support of the policy of Sir Charles Wood in respect of leaving primary education to the people themselves, with full liberty to provide, under proper inspection, for the religious and moral training of the pupils. An endeavour has also been made to bring out clearly, not only the essential importance of their religion to the Indian peoples, but also to show that the older generation now fully realises the lamentable result of neglecting it. It remains to offer some suggestions as to methods for introducing the change which seems so urgently called for. And, as a preliminary to the discussion of this part of my subject, I must refer again to the communication, already twice-quoted, from my Brahmin friend, in which he argued in favour of handing over elementary education to the people. The underlying reason was a sound

one, being based, in fact, on the principle of decentralisation. In the continent of India it is impossible to aim at uniformity; and, therefore, in the remarks which follow, it is assumed, as an unalterable principle, that, if success is to be achieved, the greatest elasticity must be allowed.

The attention of many of you must have been drawn to a series of most interesting letters which appeared in the *Times* on the subject of Education in India, from the pen of the Rev. Dr. Miller, lately Principal of the Madras Christian College. Adopting a line of argument very similar to that which I have followed in my endeavour to show that the true policy laid down in 1854 has been misunderstood and misapplied, Dr. Miller advocates greater encouragement and a more liberal financial support to those private institutions which unquestionably come within the scope of aided institutions as contemplated by Sir Charles Wood. He writes:—"If the broad principles laid down in 1854 were henceforward to be fully acted on, if liberal aid and sympathetic superintendence began to be afforded to private effort, there cannot be a doubt that schools and colleges hereafter to be founded by Hindus and Mohammedans would be based on the tenets of their faiths, and would exert an influence on the students in attendance enormously more healthy than that of the secular schools and colleges." It will be realised, from what has gone before, that I most cordially endorse this view, but that what is advocated in this paper goes very much further. I am not so familiar as Dr. Miller is, of course, with the conditions ruling in Madras, but in other parts of India, in the case of elementary schools, the proportion of institutions owing their existence to private enterprise is almost a negligible quantity, and, unless the principle is expanded so as to cover those institutions, quasi-Government schools though they be, which are supported by local funds and administered, under Government supervision, by local bodies, it is to be feared that many generations would pass away before an appreciable improvement took place. The village schools, as well as the elementary schools in the towns, are those which it is so pre-eminently desirable to reach; and though a percentage of such schools in the towns are private institutions, practically all those in the mofussil are departmentally controlled. If the view that "it is in primary schools that the foundation of moral ideas is laid"—fortified as it is, I believe, by the experience in other countries—be accepted, then, if the policy here advocated is to be effective, it must be applied more widely than is demanded by Dr. Miller.

It is, however, of no advantage to blink difficulties, and a very real one occurs here. It will not suffice, in the case of those schools, whether private or administered by local bodies, for Government merely to inspect and approve the secular curriculum, leaving the religious or moral course of training severely alone. In the case of more than one private school (*not* in Bengal) it is within my personal knowledge that the liberty to teach religion, unfettered by any check, has been grossly abused; and that the true doctrines of the Hindu sacred books have been hideously perverted to serve political ends. Such a state of things is, of course, exceptional; moreover, no degree of control could be made effective for its complete suppression. Nevertheless, it is a fact to be reckoned with, and one which makes it dangerous to subscribe to Dr. Miller's conclusion that the State should not only "abstain from interference with the religious instruction forming part of the course in the institutions which it aids, but" should "take no notice of whether religion is included in their course or not, provided they are certified to be in other respects efficient." This is an echo of paragraph 56 of the Despatch of 1854, where, dealing with the duties of educational inspectors, it was directed that "*no notice whatsoever* should be taken by them of the religious doctrines which may be taught in any school," which, if strictly carried into effect, would debar an inspector from reporting on the existence of abuses such as have been referred to. These abuses could not have been foreseen fifty years ago; and the difficulty, in adapting the general lines of the policy then laid down to the exigencies of today, lies in steering the middle course between active interference and the *laissez-faire* for which Government are so much blamed by Indian parents at the present time. It must be remembered that India is not, as England is, a country in which local authorities have always administered their own affairs and are quite capable of safeguarding their own interests. It is not only possible, but it not infrequently happens, that in India a local school, or other institution, is conducted upon lines which are cordially disapproved of by a majority of the inhabitants. Partly because of an innate apathy, more, however, on account of the tendency of the people to lean on Government, or its local representative, in all things demanding action

or initiative, a most undesirable state of affairs might continue indefinitely, without any rumour of it reaching the ears of authority, in respect of *any* matter of which the Government publicly notified a policy of rigorous non-inspection. We should, therefore, I submit, be evading our responsibilities if we went the lengths suggested by Dr. Miller. But a middle course is not altogether incompatible with the prescribed policy. Inspection is not interference. Supervision is not direction. The aim should be, by regulated instructions, to cause our educational inspecting officers, while abstaining from interference, to satisfy themselves that the religious instruction conveyed is of an appropriate, or at least harmless, character; and the regulations could be so framed as to secure that no initiative, in dubious cases, should be taken without the sanction of the local Government.

The difficulty which is always put in the forefront of those resisting the reform has now to be faced. It is stated continually, as though the statement carried its own demonstration, that the diversity of races, languages and religions, which find their place in India, is so great, and that the various religious denominations are so closely intermingled, that it would be impracticable to prepare text-books to suit all requirements or to devise means for imparting instruction in the many doctrines whose followers would be found even in the same school. It has already been frankly admitted that the difficulty exists; but there has as yet been no organised attempt to find a way out of it. It has been shown, by a reference to the adoption of the *Sanatan Dharma* text-books in so many schools, that the difficulty has been enormously exaggerated. It has also been suggested that, if the obstacles are to be overcome, the cardinal principle to be borne in mind is "Decentralisation." If the idea persists that there should be uniformity of text-book, and similarity of method, even for the same denominations, throughout the continent of India, then failure is assured. But, once it is realised that each locality will, if permitted, speedily devise its own methods, and, with the benevolent assistance, but without the direct interference, of Government officers, elaborate its own text-books, the greater part of the difficulties will vanish at once. Let me take the Bombay Presidency, with which I am, on the whole, best acquainted, as an example; and let me exclude Sindh, which is a province apart. Three, or, if Urdu be included, four main languages are spoken. The population includes Hindus of both denominations (Vaishnavas and Shaivas); Mohammedans, both Sunnis and Shias, orthodox and unorthodox; Parsis; Hindus of the Jain persuasion; Lingayets, and so forth. Let us suppose that the Secretary of State and the Government of India have issued orders permitting the introduction of religious instruction in the schools of such of the local authorities as may ask for it. The Bombay Government would doubtless convene meetings of small committees of representative men, from the distinctive localities, of such branches of the community as were affected by the demands of local authorities; and these committees, in consultation, if necessary, with the educational department, and with its assistance if asked for, would very quickly determine upon the kind of religious instruction they desired, and upon the person or persons best fitted for drawing up such text-books as might be considered necessary. And the Educational Department would render such assistance in the matter of preparation and printing as might seem justifiable and appropriate.

One objection still remains untouched. A large proportion of Indian village schools includes Mohammedans as well as various denominations of Hindus on their rolls; and it may quite easily happen that, while instruction in the moral principles of Hinduism could be arranged for in a given locality, it would be difficult or impossible to provide for the religious instruction of the Musulmans. This, I suggest, is an obstacle in the way of the complete introduction of this reform, but in no way vitiates the argument for its partial institution. Both Hindus and Mohammedans, in India, are, as a rule, extraordinarily tolerant; and it is conceivable that, rather than attend no class of religious instruction, the Mohammedans, in the case I have supposed, would attend the Hindu lesson. Thus, provided, so far as Government and the local authority are concerned, attendance for this particular subject remains optional, or compulsory on individual boys only at the express wish of the parents, the objection would not be a practical one.

It is, however, less the aim of this paper to suggest devices for overcoming the difficulties in the path of what is so universally regarded as a most necessary change in our scheme of education, than to put forward reasons why a practical endeavour should be made to assess those difficulties authoritatively—in other words, to urge that the time has now come for seriously

grappling with the problem. The moment is opportune. The first Minister for Education—a Minister who bears a name which, of itself, carries weight in the educational world—has just been appointed. He will find the ground prepared everywhere for reform. Should there still be reason for hesitation as to whether the community is ripe for the change, let a commission, or provincial commissions, composed largely of the real leaders of the Hindu and other communities, be appointed to inquire, deliberate and report; and let the subsequent line of action depend, so far as is possible with due regard to the preservation of general principles of policy, upon local conditions and demands.

There remains for consideration the question whether, if the obstacles in the way of permitting the teaching of morals upon a religious basis in Indian schools are ascertained to be insuperable, there is no alternative method. Even if this question did not thus arise in a practical shape I should be ignoring a most important factor in the discussion were no reference made to the work, in regard to India, which is being done by the Moral Education League. However strongly one may share the views of the great majority of those who, familiar with India, and with Indians in India, believe that, to be efficient in the best and highest sense, moral instruction must there, more than anywhere else, be taught in conjunction with, and upon the basis of, the religions of the different peoples, it has to be recognised that a change of policy of the magnitude involved in a subversion of the practice of more than half a century is not lightly to be entered upon; and that a false step, taken in haste, would be conceivably worse than none. There are many of those well qualified to form an opinion—and among the number some (a minority) of my Hindu friends—who apprehend difficulty, and perhaps some dangers, in dogmatic religious teaching, chief among those dangers being the inadequacy to the task of the subordinate educational staff in India. To such persons it seems at present preferable that a commencement in the reform movement should be made upon *quasi*-secular lines. In France, in parts of England, and pre-eminently in Japan, there is a tendency for moral training divorced from religion to take the place of denominational teaching; and the results, so far as can be judged, appear to be satisfactory. Although, to persons who have studied India, it will seem dangerous to draw any close analogy from the practical and progressive nations I have mentioned, and to conclude that the same results would ensue in the case of India, it is nevertheless desirable to take the alternative into consideration. At the moment, indeed, it is essential to do so. Under the auspices of the Moral Education League, Mr. F. J. Gould, with whose work in England you are probably familiar, has drawn up a book of moral lessons for Indian school children which will shortly be published by Longmans, with the title "Youth's Noble Path"; and a prominent member of the League has proceeded to India with a view to organising its dissemination and use in India. The work is admittedly tentative. In a characteristically modest preface Mr. Gould, after explaining that his chapters are to be regarded "as suggestions and types, and not as a fixed code to be rigidly followed," and after laying stress upon the dependence of success upon the teaching staff, concludes:—"I am yet profoundly conscious of the tentative character of the work, and of the immense field that still awaits the careful study of the moral instructor of Indian childhood and youth. Educationists will improve upon my imperfect achievement."

Should it, unfortunately, prove too difficult to adopt a policy which will enable local bodies throughout India to introduce the teaching of ethics upon a religious basis in the schools within their charge, there is thus, ready to hand, an alternative. Mr. Gould's book draws its inspiration from all sources, and bases its teaching upon that of all the great religions impartially. So far as I can judge, there is really nothing in it to which Hindu or Mohammedan, Parsi or Buddhist could take serious exception. Not the most fanatical political opponent of all things British could pretend that its teachings are aimed at making loyal subjects rather than worthy and high-minded citizens. And in such circumstances, should the wider policy be impossible of adoption, we shall have travelled some way in the right direction if we introduce, throughout the Government schools, the practice of systematic moral training upon a secular basis, commencing upon the model now furnished. The Government of Bombay, who in this matter are taking the lead, have already officially determined upon the preparation of a similar text-book, and I understand that the work will shortly be taken in hand. I suggest that, although the greatest weight must attach to Mr. Chirol's view that an attempt of this kind, to instil ethical notions into the

Indian mind independently of religious dogma, is bound to end in failure, nevertheless if we are debarred, in respect of a portion of our schools, from instituting a regular course of religious instruction, we should make the attempt. There is a definite demand for it; and though it may be regarded as a *pis aller*, there will be no hesitation, on the part of the majority of thoughtful Indians, in accepting it as better than nothing.

In conclusion, I desire to anticipate one reply which will be made to the suggestions here thrown out. In the review of educational progress in India issued in March, 1904, to which reference has already once been made, after the observation that instruction in Government institutions is, and must continue to be, exclusively secular, the Government of India observed that the remedy for the tendencies unfavourable to discipline, which had been noticed of recent years, lay "not so much in any formal methods of teaching conduct by means of moral text-books or primers of personal ethics, as in the influence of carefully-selected and trained teachers." With the soundness of this observation everyone must agree; but I would ask anyone acquainted with India, and especially with the conditions obtaining in the subordinate educational service of most provinces, how long we should have to wait for a remedy dependent upon an improvement in the quality of teachers up to the ideal standard contemplated. The Governments in India are doing what they can, with the resources at their disposal, to raise the pay of, and render more attractive, the lower posts in the Educational Department, in order to enlist teachers of better qualifications. In the first place, however, it is to be borne in mind that, owing to the past policy, we cannot at present hope to get material which itself has had any training in moral principles; and, secondly, years must elapse before the lower grades of this service can be so improved as to attract men of the quality stipulated for in the memorandum. The question which suggests itself to those hoping for practical amelioration within a measurable period of time, is whether it is not better to put a good text-book, on whatever subject, into the hands of teachers of questionable attainments, and require them to teach their pupils what is therein written, rather than to leave matters to drift. Moral instruction requires to be systematically conveyed, just as instruction must be systematically conveyed in any other subject. We provide the teachers with text-books on all the others—surely, therefore, we may with advantage put into their hands a book of guidance in ethics. It is neither the easiest nor the least important subject to teach; and even if we could expect workmen who have never learnt how to make bricks at once to undertake the task, we should at least feel bound to furnish them with the necessary materials.

The conclusions which this paper wishes to suggest may be summed up as follows:—

1. The policy laid down in 1854 imposes no absolute bar to the introduction of moral instruction based on religion in aided schools; and it is permissible to hold that the schools supported primarily by local bodies, and administered by them, come within that category.

2. It is in primary schools that it is peculiarly desirable that the elements of moral notions should be taught; and the vast majority of primary schools would come within the scope of the suggested reform.

3. The practical difficulties in the way of introducing the change should, if necessary, be inquired into by a Commission appointed for the purpose; but these difficulties will be greatly diminished if it is once decided that uniformity of procedure and method throughout India is unnecessary and undesirable.

4. The demand for some measure which will make good the deficiency in the educational system is so urgent that, if the difficulties confronting Government are found to be insuperable as regards the introduction of moral instruction upon a religious basis, a scheme of secular moral instruction, modelled for the present upon the work of the Moral Education League, should be given a trial throughout all schools with which Government are concerned.

DISCUSSION.

The CHAIRMAN (Lord Northcote) was sure all present would feel that Mr. Hill had dealt with the great question of Indian education in as comprehensive a way as it was possible to deal with so vast a subject within the limits of time to which the paper had to be confined. Mr. Hill had touched upon some of the notorious weaknesses and defects of the present system of education in a manner which entitled him to the Society's cordial thanks. He (the Chairman) would refer particularly to one of the concluding points of the paper, which urged that text-books, such as were indicated, might with great advantage be furnished to the teachers in rural schools in India. All knew that under existing circumstances the pay and position of the

teachers in the smaller schools in India were so extremely low that it was impossible to get the best men to undertake the work. He thought it was, therefore, essential that there should be furnished to those men, who for some time to come must continue to educate native children, every help which could be given them by a good text-book, in order that they might be enabled to inculcate moral lessons. He also thought there was much to be said for the suggestion that a Commission should be appointed to inquire into the general subject of Indian education, which Commission should report to the Government in what way any schemes for its improvement might be carried out. He need hardly say that he should attach special importance to the report of such a Commission if it were very largely, or, indeed, mainly, constituted of native Indians, who would be better able to judge of the requirements of their fellow-subjects than Europeans.

Sir Theodore Morison, K.C.I.E., said, while he was in substantial agreement with the paper, there were one or two points as to which he did not agree with Mr. Hill. In the first place, in regard to both the paper and also to Mr. Chirol's book, he thought there was a danger of losing the perspective, because of the troubles directly connected with English education which were at the present moment in everybody's mind. People were rather apt to overlook the very great and beneficent revolution which English education had achieved in India. It was but a very short time ago when the morality of Indian public servants was more than open to question, but at the present time the universal evidence of all English officers was that those Indians who had received an English education were absolutely trustworthy. There was a Chief Justice in the province in which he (Sir Theodore) served, who used to say: "If you will tell me those men in the judicial service who have received an English education, I will tell you the honest and incorruptible judges." In a great many other spheres of native life the same remark applied. It was the universal testimony of Indians themselves that the mere acquisition of English education had wrought an extraordinary change in the morality of the people. In asking many Indian gentlemen to what they attributed such a great change from the mere fact of an English education, the answer had always been: "It has freed us from the thraldom of authority." Could anybody deny that that was a perfectly legitimate deduction from English literature? Was not English literature, from the time of Queen Elizabeth down to the present day, one long pæan of liberty and the exaltation of the duty of private judgment? That being so, was that going to be arrested by anything short of stopping English education altogether? That he thought was out of the question. Secondly, was it thought that the giving of religious education was going to arrest that stream of thought and new ideas which were surging through India? His own experience was that the old orthodoxies were crumbling away, and that they were perfectly powerless to resist the stream of modern thought. He had had a good deal of experience in regard to religious education in India, and if anybody imagined that the very strong public opinion which existed in Aligarh was due in any way to religious education, he felt it his duty to reply that it was not. The influence of religious education at Aligarh had been very small. What had been very powerful, and what was a great engine for good, was the tone and the traditions of the place, which he believed could only be got in a denominational institution.

Sir J. D. Rees, K.C.I.E., C.V.O., thought that one, at any rate, of the texts from which Mr. Hill had preached needed no emphasising, namely, the fact that a certain class of education—which did not need pointing to—was a powerful solvent of the Hindu—he would not say of the Mohammedan—religion. He remembered some time ago, when he was on the staff of the Governor of Madras, going to the borders of the Presidency over which the Chairman had ruled with such distinction, where there was a forest in which were some deserted idols. It was a beautiful forest, with gushing fountains, blue sky, sparkling sea—everything that was beautiful and romantic. He asked the Governor to go and see the idols and the deserted temple. On going the next day, they found the idols had been anointed with oil and flowers strewn before them. The Governor asked what it all meant; he had been told that it was a deserted temple. The tehsildar replied that he had had the idols washed and worshipped especially for the Governor's inspection! On being asked what his own view of religion was, the tehsildar replied: "Having received an education of an English character in a University, I have no religion left." He also vouchsafed the information that a Government officer had no time for religion. He (Sir John) did not put that gentleman forward as being a type of the product of English education, and it might be that Sir Theodore Morison would say that what was the matter with the tehsildar was that he had not had education enough. But there was a moral in his story. When he was at Whitechapel a few nights previously, preaching anti-Socialism and talking about India, he found the people in that district evidently thought that the products of English education who came home here and pretended to represent India really did represent the inhabitants of that vast sub-continent, and at any rate they were people who invariably had lost their own religious beliefs. That was a very important matter, and he agreed with Mr. Hill and not with Sir Theodore Morison upon that point. He remembered that when the Reformers, that peculiar product and fine flower of new education, began to get powerful in India, the greatest plank of their platform was the renunciation of Hinduism. He could

quote authorities to prove that that was their attitude in the beginning. They did not maintain that attitude, nay, they deliberately renounced it, and were now revivalists of Hinduism. Everybody would admit that those who had received an English education in India were making admirable public servants. But the theory put forward by Sir Theodore seemed to imply that the public servants in India, and in particular the judges, were not to be depended upon, and were not honest, unless they had received an English education. From that view he entirely dissented. He believed there were men who were as honest and as upright amongst the Indian and Mohammedan peoples who had not received such an education as amongst those who had. For his own part he did not believe that the morality of the one class was superior to that of the other. Sir Theodore had also said that the result of English education was to free the Indian from the thraldom of authority. He (Sir John) admitted that was the result, but he also claimed that that freedom from the thraldom of authority had been carried to a dangerous extent, and liberty had degenerated into license. He believed that the measures suggested by Mr. Hill would have an admirable effect, and that they would not arrest, as Sir Theodore said, the stream of thought which had set in a certain direction. He (Sir John) believed that the stream could not be altogether arrested, but might be diverted, and that the adoption of Mr. Hill's suggestions would control and turn it into a new channel, with very great benefit to those who underwent an English education. He could not help dotting the i's of one suggestion of the author's. Mr. Hill said that the measures he suggested could probably be carried out with greater ease on account of the admirable tolerance of the peoples of India. There were many things in which the inhabitants of India set a good example to the people of Europe, but in nothing more than toleration. An Education Bill could not be brought before the House of Commons without violent disagreement among the Churches. In India, however, there had been no difficulty arising from the fact of the Hindu and the Mohammedan being in the same school. So far from there being any intolerance, both the Hindu and the Mohammedan united in giving the highest honorific ecclesiastical title they possessed to the English missionary, who did not always imitate that tolerance. He favoured Mr. Hill's suggested Commission.

The Rev. Dr. J. E. Marks said he knew very little with regard to education in India, his life having been spent in Burma, but there was a great deal with regard to education in India which was applicable also to the Province of Burma. It had been his lot to work in that province as an educationist and as a teacher for over forty years, and he hoped yet to return there. Although he agreed generally with the paper, there was one point which he thought the author had missed, namely, that the Government, while it properly abstained from interfering with religion in Indian schools, should be careful to be perfectly impartial in its patronage of the education carried on by missionaries and private institutions. In Burma there was a well-educated population; there were no illiterate people, and the Burmese knew their religion well. Buddhism, while it made every boy a pupil and every man a teacher, was marvellously tolerant of every institution. He went to Burma in 1859, an unknown man, and poor, as a missionary always was. The Burmese built for him colleges and schools all over the country; he had never had to ask a penny from England on that account. The result was that he had taught fifteen thousand of the boys of Burma. As an instance of Burmese toleration, he might mention that the King of Burma, hearing of the schools in Lower Burma, invited him to the capital, Mandalay, and there built for him a grand school, a church, and a house for his residence, and sent nine of his sons to the school to be taught. The King, Mindorn Min, said to him: "I do not say that I wish to become a Christian, but I do acknowledge that your nation is the strongest that has ever come to Burma. You have conquered the Burmese, which no other people has ever done, but although you have conquered them, you have not made them slaves, as others would have done; you have given them equal rights with yourselves in your courts and in your markets and in your private intercourse. You tell me that the secret of your justice and of your might and of your kindness lies in your religion, and I wish my sons to learn that religion." Yet that king was the recognised Defender of the Buddhist faith. The Burmese kingdom was now at an end; and what had happened? The Chief Commissioner of Burma, Sir Ashley Eden, had tried to smash the college—St. John's College, S.P.G.—in Rangoon. That gentleman had written saying that unless it was sold to Government, Government aid would be taken from it—one-half the first year, two-thirds the second year, and everything the third year. Sir Ashley Eden wished to ruin the college "lest it should be a rival institution" to the secular college. He (the speaker) refused the terms utterly, and declared that it would never be sold to Government, but that it would continue as a Christian missionary college. That same spirit had gone on increasingly in Burma. No effort had been made to kill such colleges, but the authorities had tried to let them die. They had tried so to make a distinction between the Government secular institutions and the missionary institutions, that people should see the difference, with the result that the Christian missionary schools, which the people loved, had the greatest difficulty in maintaining themselves. The people of India were thoroughly tolerant; and if only the Government would be impartial to such Christian missionary schools, and give them fair play and the same advantages they were giving to the secular schools, he was quite sure that the difficulties which the author had so well and properly pointed out would in a great degree vanish.

Mr. M. T. Kaderbhoy desired to refer to the question of compulsory education, which, if it was to be of any use in India, must be very carefully considered in all its aspects. Compulsory education in India would present many difficulties to an Indian, who would fear the introduction of such a system, thinking it would deprive him of his own particular education, which was based on Eastern learning. If a system of compulsory education was introduced in India, it must be either completely English or completely Indian, otherwise it would turn out Indians who would neither be a credit to their own education nor to the new system of education. He sincerely trusted the Government would seriously consider whether the suggestion would be generally approved of by Indians.

Mr. R. A. Leslie Moore said he failed to see that Dr. Marks's observations with regard to Burma had anything to do with the paper, seeing that the paper was confined to India. He, however, believed the fact to be that the Government—in India, at all events—had shown fair play to missionary schools. He also thought the remarks of the last speaker were outside the paper, which dealt with the religious aspect of English education. Sir Theodore Morison had said that the high tone of the Aligarh College was not owing to religious teaching, but to the traditions of the place; but he would ask Sir Theodore: How had those traditions sprung up if they were not the outcome of religious teaching? They were probably as much due to the tenets of the Koran as modern civilisation in Europe was to Christianity. Sir Theodore Morison had also said that English education—by which he presumed Sir Theodore meant education given by the Government of India in India—had produced a very incorruptible body of Civil servants. That was in the main true, but Sir Theodore had omitted to notice that it was that same education which had produced the frightful crimes that had occurred in India during the last few years. He (Mr. Moore) was, however, thoroughly of opinion that if Mr. Hill's scheme of religious instruction could be taught when the minds of the pupils were fresh and plastic, the result would be that the rising generation would recover that self-restraint and that respect for authority which had marked the generations that had gone before, and which had resulted in a race marked for its moderation and courtesy. Stress had been laid upon the necessity for the impartiality of the Government in Indian education. Was it not possible for the Government to maintain that impartiality by fostering all kinds of religions? He thought it might be interesting if he read a resolution of the Maharaja of Mysore on that point. It was as follows: "The time to be given to religious and moral instruction will be limited to five periods a week, the first thirty minutes after roll-call being devoted thereto. There will be a moral discourse on Mondays, Wednesdays, and Fridays, and religious instruction on Tuesdays and Thursdays. The moral discourse will be common to all persuasions, and based on a text taken from some religious, moral, historical, or literary book. In addition, there will be specific religious teaching from books like the *Sanatan Dharma* advanced text-book, the Koran, and approved commentaries and essays on the Mohammedan religion and the Bible." That was an order of an Indian prince with regard to the education of the children of all his subjects, not only Hindus, but Mohammedans and Christians. Was the example too high for imitation by the Government of British India? With regard to the teachers, he was well acquainted with many of the primary schools of the Bombay Presidency. In those schools the monthly pay of the assistant teacher was often seven rupees—9*s.* 4*d.* He asked the members to imagine the guides, philosophers, and friends of the Indian school-boy on 9*s.* 4*d.* a month! He would like to make a suggestion in that connection, namely, that less should be spent on bricks and mortar in erecting schools through the costly agency of the Public Works Department, who worked well but expensively. He suggested that the buildings should be erected by the villagers themselves, with the aid of local board overseers, and that the surplus should go towards the better remuneration of the teachers.

Mr. Reginald Murray sympathised most cordially with the author's suggestions as to the question of moral teaching in India, if explained and demonstrated by capable lecturers. He felt sure that such teaching would be acceptable to all sects and would offend none. He might recall, as an example, a Hindu of high caste, a strict Brahmin, most regular in his daily religious observances, who habitually carried about with him a volume of the "Christian Year," much of which he knew by heart. The reason he gave was that the thoughts in the book were so beautifully expressed that they aided him greatly in his meditations. With regard to the supposed difficulties which occurred between religions, one had only to look at the bridge which was being made over that great chasm which had separated for so many years science and religion in this country. If a bridge could be constructed over such a broad gulf as that, surely there could be no difficulty in bridging over the small clefts which divided the religions of the world. With regard to education generally, he might refer briefly to his own experience. He had found most of the young Indians applying for clerkships fairly efficient in handwriting and simple arithmetic, but ignorant of everything else. They lived at some distance from the offices in which they were employed — an economical necessity — so that their employers could do nothing to assist them in furthering their education. He would suggest that those young men might be encouraged to continue their education by means of evening classes in the districts in which they resided. No expensive buildings would be required, and the fees of instructors would be paid partly by

the students. He thought employers might not be averse from supplementing the fees with the prospect of improving the efficiency of their staffs, the instructors being appointed by the Government and being well-paid and capable men. The great advantage of such a system would be that book-learning and theoretical knowledge would become adjuncts to practical experience—a very desirable combination.

Mr. Syed Abdul Majid, LL.D., considered that if a measure were adopted giving compulsory education to Indians in the religions of their forefathers, grave consequences would follow. In the first place, it would give rise to a priestly class, and if history taught anything, it taught that if that class was in power, the march of progress was hampered and kept back. When the Government scheme was being introduced into India, a great deal was heard about the depressed class. There were about sixty-one millions of people who had been kept down by the priests in India. Their condition could only be improved by education, but if that education was given into the hands of the priests, their condition would remain as deplorable as before. Religion, in itself good to a great extent, was not an unmixed blessing; it always created class differences. The one policy of the British Government should be, whether with Hindus, Mohammedans, or Parsis, to create one nation called the Indian nation, and that evolution could not take place unless and until all those classes received an entirely European education. People asked the question: How do you account for the unrest in India? It was not because Indians had forgotten their religion. Indians had been taught, as it were, purely on a literary basis; they had been taught Shakespeare, Milton, and Tennyson, but they had not received any technical education at all. The very end of education was to create happiness and comfort, and if the British Government really aimed at educating the people of India they should handle the question in a more serious way, and give them the education that they really required, namely, technical education. The people would then be able to earn their livelihood much better than they were at present able to do, and such a system would do away with all the prevailing unrest. He challenged any person to name a single Indian who had received a high education who was not a supporter of the British Government. The best supporters of British rule in India were highly-educated Indians. The unrest existed among those who could not get enough to live upon because the economic conditions of the country were not developed.

Sir William Lee-Warner, G.C.S.I., in proposing a vote of thanks, remarked that the treatment was as excellent as the subject. The question was one of high and immediate importance, and the issues raised by Mr. Hill were precise and thoughtful. Whether moral instruction could be torn out by the roots from various religions, and still germinate and fructify principles of life and conduct, he was himself more than doubtful. But he would not enter into a discussion at that late hour. The whole subject needed thought, and above all an expression of the opinions of leading Indians upon the issues raised. Sir Theodore Morison had hardly touched them. Dr. Marks had contributed a useful suggestion, for many thought with him that aided enterprise needed more fostering care and fairer treatment for purposes of development. Dr. Miller's recent contribution to this subject deserved the careful attention of all. Mr. Kaderbhoy and the last speaker seemed to have introduced a new subject, but perhaps their speeches were meant to enforce the need of caution, on the ground that if Government made education compulsory their motives would be misconstrued if they introduced facilities for religious teaching. Perhaps that might be the case. But compulsory education was a very long way off, and if introduced now half the existing schools would be starved to death owing to the loss of fee income. The Society owed much to Mr. Hill for his paper, and to Lord Northcote for presiding and contributing some really valuable thoughts to the discussion. He was confident that the meeting would express its hearty thanks to both the Chairman and Mr. Hill.

Sir James Wilson, K.C.S.I., in seconding the resolution, said his experience of the subject had been confined to the Province of the Punjab, but in a matter of the sort under discussion there was not, perhaps, so great a difference between the various provinces of India as there was in other matters. In the Punjab there were Hindus, Mohammedans, and Sikhs, all differing in religion and all very anxious that their children should be taught their own particular religion, but, notwithstanding that, they were extremely tolerant amongst themselves, so long as no one attempted to convert their children or relatives from one religion to another. He thought the Government was bound to take that strong feeling of the people with regard to their religion into account, but it was quite possible for the Government to be neutral and impartial without ignoring religion altogether. He had been very much struck by the phrase which Sir Theodore Morison had quoted—that one effect of our education in India had been to free the people from the thraldom of authority. That, he thought, was the great fault of the present system. It seemed to him that history showed that the majority of people, not only in India but elsewhere, were better under a certain amount of authority, and that children and young people should be taught to obey their parents and teachers, and spiritual leaders. With regard to the question of moral training, he agreed with Mr. Hill that it would be very useful indeed to have a manual of moral instruction drawn up somewhat on the lines of "Youth's Noble Path." He did not think it would be at all difficult, even where people differed so much in religions, to draw up a moral education manual which would be acceptable to all parties;

but he would go further and say that the Government ought to make the teaching of religion—a all events, in the primary schools—easy for the parents. The Government, with its district boards and municipal committees, should organise a system of religious education, subject to inspection, and so help the parents to have their children taught the religion which they wished them to be taught.

The vote of thanks was put and carried.

The CHAIRMAN said he had been very amply repaid for his trouble in attending the meeting by hearing such an excellent paper and the very interesting comments on it.

Mr. HILL, who was prevented by the late hour from replying at the meeting to the discussion, writes as follows:—I am extremely grateful for the kind reception which was given to my paper, whose unavoidable length, I fear, curtailed the discussion which might have proved of greater value than the paper itself. It is most gratifying to me to find that the views I put forward meet with such general acceptance at the hands of Sir Theodore Morison, Sir John Rees, Sir James Wilson, and of the Chairman, and only a few words seem to be called for in reply to the remarks of the first-named, and to remove what appears to be a misunderstanding on the part of Messrs. Kaderbhoy and Abdul Majid. If I understood Sir T. Morison correctly, his contentions were—first, that English education had wrought a wonderful revolution in the standard of public morality and honesty in India; secondly, that the religious instruction imparted in the Mohammedan College at Aligarh had had little or no influence upon the students; and, lastly, that it was the tone set at that institution which brought about its satisfactory results. In regard to his first point, I am content to leave the question in the position in which it was placed by Sir John Rees; only observing that my paper nowhere attempted to suggest that English education had been devoid of results, or should be superseded by a radically different system. The position, as it presents itself to me, might be illustrated thus: In our educational system we have an excellent piece of ordnance, of sound metal and, on the whole, excellent workmanship. But its sighting has been found to be defective. In cases where it hits the mark its execution is admirable; but, owing to the defect in the sight, it sometimes misses its objective. The aim of my suggestions was, not to scrap the gun, but to remedy what is so universally recognised as a defect. I do not think that Sir T. Morison's view as to the absence of influence of the religious teaching in the Aligarh College would be supported by others who have been connected with that institution; and the impression I have derived from conversation with His Highness the Aga Khan and other influential Mohammedans is directly at variance with the views enunciated by Sir Theodore. And when it is claimed that it is the "tone" of the institution which accounts for the superiority of its products, I should like to inquire what cause it is that induces that tone. Mr. Abdul Majid, following Mr. Kaderbhoy, who dealt with the urgency of an extension of education, urged strongly that religious instruction should not be made compulsory. I fear that I cannot have made sufficiently clear the policy which I ventured to advocate. That policy involves, as a condition precedent to the introduction of moral instruction, what may be called "local option"; and, further, leaves to parents the choice whether their children shall, or shall not, be compelled to attend the religious or moral lessons. I think this explanation will remove Mr. Abdul Majid's anxiety.

Mr. EDWARD GILES, C.I.E., late Director of Public Instruction, Bombay, writes:—It appears to me that it is possible to agree and to disagree with nearly all those who spoke on this subject. Mr. Hill put his case ably and moderately before the meeting in his paper, but it struck me that he argued too much on the presumption that a secular system of education had not only produced unsatisfactory results, but was mainly responsible for that condition of unrest and for the worst form of political agitation which is so much to be deplored. He appeared to ignore the fact that a development of political and social unrest has taken place of late years in all the leading countries of the world, and that it is impossible that it should not, in these days of rapid communication and constant intercourse between nations, have affected India largely. He also, I think, failed to appreciate the enormous harm which has been done in India by a vernacular press, which has for many years exceeded all the moderate limits of decent journalism, and which has not ceased to depreciate and throw dirt at the Government of the country. Such a demonstration of license, so contrary to all the customs and traditions of Oriental rule, has, in my opinion, done far more to undermine and upset the native mind than the mere absence of direct religious teaching in the schools. And the press has been assisted by political propaganda of the worst kind, deliberately preached and insinuated by certain bodies of malcontents in various centres. Not long before I left the Bombay Presidency, the Principal of the large Vernacular Training College * at Poona, a noted centre for the exercise of Mr. Tilak's energies, came to me, and with tears in his eyes deplored the fact that young men, who left his college to be teachers in primary schools, were exposed to the direct influences of Mr. Tilak and his associates, who did all in their power to lead them astray while they were young, and to induce them to use their position in a village school for the diffusion of disloyal sentiments among the village people. It is well known that in the Deccan and in the Central Provinces Mr. Tilak's lieutenants and followers are neither few in numbers nor weak

* It sends out some sixty to seventy masters annually.

in influence. Similarly, from Bengal for years emissaries of the extremist party have been active all over India, coming as far as Ahmedabad in Gujarat, and Sindh, with the express purpose of disseminating their views and of stirring up discontent. It is well known also that in many places, and certainly in the Punjab, the propagation of political theories of the worst kind has been the work of so-called religious societies. I would ask whether this development in India could ever have been prevented by the inclusion of religious instruction in the institutions for which Government is either directly or indirectly responsible? Sir Theodore Morison appeared to me unduly to depreciate the influence of religion in the case of the Aligarh College. I should prefer to think with Mr. C. W. Waddington, the able Principal of the Mayo College at Ajmir, who showed me his 150 Rajput boys of princely blood going twice a day to prayers in the temple in the grounds, and expressed the opinion that it had an excellent influence on them after the stress of work and play, and in the early morning as a commencement to the duties of the day. But this is an exceptional case, and it must be remembered that among the Hindus generally there is no direct religious teaching or preaching, even in the temples, and that the individual attends a temple for the recital of prayer and the performance of ceremony, and not to listen to the exhortations of a preacher. This fact must always be borne in mind when we are criticising the secularity of our State schools. In Poona, when I wished to provide direct religious teaching for the Hindu boys of the Jerowda Reformatory, I was informed by such an authority as Dr. Bhandarkar that it would not be possible to obtain the services of a Brahmin priest to instruct the boys in their religion, unless he was very well paid for it!

The moral text-book offers a very inadequate solution of the difficulty. In 1883, Mr. Justice Telang, one of the ablest members of the Educational Commission, directly opposed the introduction of a moral text-book, and though the Commission recommended its preparation the idea was finally abandoned. Mr. Gould's effort to prepare such a text-book may be successful. If it is, I should certainly advocate its translation into all the vernaculars and its use in all schools, not as a lesson to be learnt by heart, but for teaching to be given perhaps once or twice a week. No harm could come of such procedure, and presumably good would result, if and so long as the teaching was intelligent and did not degenerate into vain repetitions. The constant use of moral phraseology and the repetition of religious maxims may defeat its own purpose, and we may arrive at last at the state of Thackeray's hawker in the streets of Constantinople, whose cry was, "In the name of the Prophet! Figs!" The gradual improvement of the teaching, however, is, perhaps, an existing fact in India, and, if this is so, the hope for the proper application of a moral text-book may be allowed to strengthen; nor was it necessary for Mr. Leslie Moore to speak disdainfully of a teacher on seven rupees per mensem, for that is, in the Bombay Presidency, the salary of the lowest assistant in a school, who will hardly, under proper direction, be entrusted with the exposition of the moral text-book. If such can be produced, worthy of universal adoption, I agree with Mr. Hill that the experiment should be tried.

But I have far more faith in the native of India than some, apparently, of the speakers, and I think that, in the whole discussion, there was a tendency to forget that behind the noisy band of agitators and sedition-mongers there lies the enormous mass of people who are quiet, orderly and contented. I have great faith in the character and religious impressions of the people themselves, and I have still more faith in the loyal servants of the Government, whose efficiency strengthens annually, and whose devotion to duty is, according to my experience, equal to that of any Western community. For thirty-five years I was continually among the people and among their teachers, from the heads of colleges and high schools to the masters of little village schools, and I have seen how nobly they work and how zealously they do their duty. Among so vast a population there will always be some, many even, who are bad, but the vast majority are good, not through European teaching and example only, but from their own inherent and hereditary characteristics. As India advances in material prosperity, in enlightenment, and in the knowledge and appreciation of true political progress, the necessity for direct moral instruction will, I imagine, become less apparent, and the increasing power of public opinion, the development of communications, and the interweaving of interests will produce a community more and more closely knit together, and more and more susceptible to those influences which make for truth, peace, justice and right. India, under a settled and powerful rule, will work out her own salvation, or will, if that rule is relaxed, be lost in one gigantic convulsion, which will not be delayed by the application of a moral text-book.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 22nd, 1911; Professor John Millar Thomson, LL.D., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Curtis, Professor Mattoon Monroe, A.M., Ph.D., 2045, Adelbert Road, Cleveland, Ohio, U.S.A.

Farrington, Henry, M.Sc., B.Eng., Popular Mechanics Company, Chicago, Illinois, U.S.A.

Howarth, Joseph, Kirkdale, Oldfield Lane, Dunham Massey, near Altrincham, Cheshire.

Samaddar, Professor Jogindra Nath, B.A., The College, Hazaribagh, Bengal, India.

The following candidates were balloted for and duly elected members of the Society:—

Barnes, Carl L., M.D., LL.B., 1977, Ogden-avenue, Chicago, Illinois, U.S.A.

Carroll, Alexander Ernest, Assoc.M.Inst.C.E., 7, Appion-way, Dublin, Ireland.

Crump, Colonel Malcolm Hart, Room 2, Elks Building, Bowling Green, Kentucky, U.S.A.

Darling, Charles Robert, Beechurst, 186, Eglinton-road, Plumstead, Kent.

Field, George Moyle Robert, M.Inst.C.E., 203, Coleherne-court, South Kensington, S.W.

Goldschmidt, Dr. Hans, 98, Bismarckstrasse, Essen-on-the-Ruhr, Germany.

Mason, Frank, M.Inst.M., 37, Carrington-road, Endcliffe, Sheffield.

Pitkin, Rev. John, Shapwick-cum-Ashcott, near Bridgwater, Somerset.

Wale, Charles, 8, Great George-street, Westminster, S.W.

The paper read was—

THE MANUFACTURE OF PORTLAND CEMENT.

By A. C. Davis, F.C.S., Assoc.Inst.C.E.

Although I propose in this paper to confine my subject particularly to the methods of manufacture as adopted in the industry in this country, yet the progress that has been made in recent years by manufacturers of Portland cement on the Continent and in the United States of America and Canada, will call for comment where such progress differs materially from our own methods.

At the present time, however, the British cement-maker generally is as up-to-date in his methods of manufacture as any of his competitors over the world, but it has only been within the past ten years that we have awakened to the seriousness of foreign and home competition, and have aroused ourselves from the undesirable state generally arising from affluence and inactivity.

Portland cement was originally invented in England some three-quarters of a century ago, and the British makers adhered solidly to old-fashioned methods for some decades. These at last had their day. But whilst we were dormant, our foreign rivals not only copied the manufacture of this invaluable product from us, but actually improved upon it to such an extent, that their industrial conditions, as far as cement-making is concerned, have been a revelation to us. For some years, however, the British cement-maker has been actively engaged in building modern works and putting down up-to-date plant in his obsolete factories, with the result that for quality of product, combined with low cost of production, the British manufacturer has nothing to fear from oversea competitors, and British Portland cement to-day has no rival in quality the world over.

The debt which we owe to Portland cement is hardly recognised as widely as it should be. Its invention alone has rendered possible many of the extraordinary architectural, and more especially engineering, feats of the last century, its durability far exceeding iron, bricks, and building-stone. Its present excellence is the outcome of years of patient scientific investigation and study, and although the names of those inventors and perfecters who laboured principally during the first half of the nineteenth century are forgotten, or at least but dimly remembered, the result of their work has originated and assisted design to an extent as great as, or perhaps greater than, has the introduction of mild steel for constructional purposes.

The application of cement in general construction covers so wide a sphere of influence that each year finds it successfully employed for some new work, and numerous evidences of this point to the great strides which have been made during recent years in the science of the manufacture of this invaluable product.

Bridges, breakwaters, docks, canals, dams, reservoirs, cement-concrete streets and footpaths, with their remarkable neatness and evenness, together with partitions, roofing tiles, building blocks, boats, barges, and caissons, and to-day entire buildings (such as the new Royal Automobile Club and the new General Post Office) represent a few of the important works constructed with Portland cement. These illustrations mark but the beginning of the era of cement in the field of engineering and architecture.

As to the permanence of works executed in concrete, this has been very fully recognised from ancient times.

Vitruvius Pollio, a celebrated architect of the time of Augustus, Emperor of Rome, describes concrete as one of the most valuable building materials which for centuries before his time had been used for foundation walls and all structures where great strength was required.

The great dome of the Pantheon in Rome, 142 feet in diameter, was built entirely of concrete, and remains to this day an example of durability, having resisted the destructive

influences of Nature for well-nigh two thousand years.

The cementing material of past ages, however, was no doubt more akin to what we now know as hydraulic lime than the comparatively modern product, Portland cement.

As to the history of cements, the first information we can find in regard to the discovery of this product or its allied materials is in the records left by that eminent English engineer, John Smeaton, who, during the construction of the third Eddystone Lighthouse in 1757, discovered that a calcined mixture of lime and clay possesses the property of hydraulicity. It is reasonable to suppose that the material which Smeaton then prepared was what we should term an hydraulic lime.

L'ttle notice was, however, paid to Smeaton's discovery, and some fifty years later the French chemist, Vicat, followed Smeaton's observation to its natural and logical conclusion, and made another step forward in burning together finely-pulverised chalk and clay, after having mixed them into paste. His process, however, received little attention.

In the year 1824 we have the practical commencement of the manufacture of what we know to-day as "Portland" cement, when the English mason, Joseph Aspdin of Leeds, found that by mixing in certain well-defined proportions finely-pulverised chalk with the clayey mud of the River Medway, and burning the same at a high temperature, he was able to produce a hydraulic binding far exceeding in quality any product known up to that time. This material possesses the delicate grey colour of Portland *stone*, and thus received the name of "Portland" cement, which formed the subject of Aspdin's oft-quoted patent of October 21st, 1824.

It is safe to assume that the Thames Tunnel, constructed in 1828, was the first engineering work of importance in which Portland cement was used. The price at that time, by the way, was 21*s*. per cask at the works, while to-day a far superior quality product can be purchased at some 4*s*. per cask, so much have the conditions of the industry altered in the past three-quarters of a century.

Now, what is Portland cement? The term "Portland" is limited to a hydraulic cement containing a large percentage of lime, and at once distinguishes the valuable constructive material bearing that title from other cementitious substances.

As the classifications of hydraulic products vary, so do the definitions of Portland cement, and the opinions as to what shall be included in the term. To be perfectly clear, then, as to what Portland cement actually is, I may perhaps refer to the official descriptions of the product in the largest cement-consuming countries, viz.:—

The British Standard Specification defines Portland cement in the following terms: "The cement shall be prepared by intimately mixing together calcareous and argillaceous materials, burning them at a clinkering temperature, and grinding the resulting clinkers."

The Association of German Cement Manufacturers defines cement, generally, as follows: "Portland cement is an article produced from an intimate mixture of the materials containing lime and clay as principal ingredients, burnt to a clinker, and afterwards ground to the fineness of flour."

In the French Government Specification Portland cement is defined as: "The product of the grinding of clinkered rock, obtained by the burning to the point of softening of an intimate mixture of carbonate of lime and argillaceous matter, rigorously combined and chemically and physically homogeneous in all its parts."

The American Standard of Portland cement defines the term as: "The finely-pulverised product resulting from the calcination to incipient fusion of an intimate mixture of properly-proportioned argillaceous and calcareous materials, to which no addition greater than 3 per cent. has been made subsequent to calcination."

It will thus be seen that from a study of these various descriptions we really arrive at the point that Portland cement is a chemical product obtained by the preliminary mechanical combination of carbonate of lime with silica and alumina, which, after passing through the succeeding stages of manufacture, becomes a mixture of silicates and aluminates of lime.

The centres of the manufacture of Portland cement are well distributed over the country, as will be here seen from the map which has been prepared to show the location of cement factories in England.

The normal size of a factory is one having an output of some 500 to 1,000 tons of Portland cement per week, and in this country alone we have some eighty cement companies with a total output of some 3,000,000 tons of cement per annum, which is equal to 15,000,000 tons of concrete or 8,350,000 cubic yards—the contents of a wall 6 feet wide, 20 feet high and 350 miles

long, which could only be constructed at a cost of five million pounds sterling.

Portland cement can be produced from any raw materials containing constituents capable of yielding by calcination the silicates and aluminates of lime which form its chief components, and the necessary constituents of these raw materials are lime, silica, and alumina. Small additions of iron oxide are desirable for fluxing these materials.

The raw materials used for the manufacture are therefore carbonate of lime, usually in the form of chalk or limestone, and silica and alumina, usually in the combined form of shale or clay. The two materials for the necessary combination indispensable for the manufacture of cement are not always found upon the same site. For the Thames and Medway works, as an instance, a usually flinty chalk deposit is found on the site where the works are situated, and this, together with mud taken from the Rivers Thames and Medway, is used in the manufacture. On the other hand, the Cambridgeshire works are able to obtain from one deposit the necessary raw materials for the manufacture of Portland cement.

The suitability of locality depends upon the manner of the occurrence of these requisites, the location of the deposit with respect to the cement-consuming market and the fuel supplies; for since with every ton of cement manufactured there will be used half a ton of coal, the location of the factory in regard to cheap fuel supplies is quite an important factor.

If it were at all possible to find a geological formation of uniform composition containing exactly the right amount of naturally-mixed chalk and clay, Portland cement could be made from it by the cheap and simple method of merely burning lumps of the material as quarried. But since such a material has not been discovered in quantity in this country, this method of manufacture is hardly practicable, for a variation of even 1 per cent. of the proportion of carbonate of lime in the raw materials, to say nothing of the irregular composition of the other ingredients, is sufficient to destroy the reliable quality of the resultant cement.

In manufacturing Portland cement, however, carbonate of lime and clay are first efficiently and accurately amalgamated in certain fixed proportions, either by the addition of water to the raw materials, or by the fine grinding and mixing of the same in their dry state.

The composition of a prepared mixture of these raw materials should be, roughly, three parts of chalk to one of clay.

The various raw materials employed in the manufacture of Portland cement at the present day may be described as follows:—

In the Thames and Medway districts the chalk formation on the banks of these rivers is quarried, and this material is mixed with the deposits of mud found in the estuaries and creeks. These chalk deposits have a depth of 100 to 300 feet, and the excavation is done by manual labour. The greater part of the clay used by the Thames and Medway manufacturers is this alluvial mud I have referred to, which is a salt-water deposit. These two raw materials are mixed together in correct proportions by what is called the wet process of manufacture, to which I will refer later.

The chalk marls around Cambridge have been well proved to be eminently suitable for the manufacture of a first-class quality cement. The "marl" is a deposit of calcareous and argillaceous material found at the base of the local chalk. It differs from the main mass of the chalk above in the quantity of the clay it contains, as might have been expected, seeing that the chalk deposit succeeded a deposit of fine gault clay, and it is probable that during the changing geological conditions the sea would not be at once cleared of mud.

It is a curious fact, and one worthy of note, that the chalk marl of Cambridgeshire—though the relative quantities of chalk may vary from yard to yard in depth when testing on the face of the quarry—contains in the aggregate about the same proportion of calcareous and clayey material as is obtained artificially by the mixture of chalk with alluvial mud in the Medway valley. Therefore, along the outcrop of this chalk marl, cement works have of recent years proved the value of the Cambridge deposit from a cement-making point of view. The deposit is, in the most favourable conditions, found about two feet below the surface, and runs to a depth of from 30 to 60 feet.

The calcareous content in the material, being in a measure the most valuable and most important ingredient from a cement-making point of view, is shown from various analyses to average from 70 to 80 per cent. of carbonate of lime, and the remaining constituents are exactly the amounts of silica, alumina, and oxide of iron required for the manufacture.

It is only safe, however, to treat these marls under a perfect scientific cement-making process, which I will explain later; the manufacture is

therefore so arranged that the "lower chalked" marl is intimately blended by a process of dry grinding with a material containing an excess of lime carbonate in order to produce a working average of, say, 75 per cent. $CaCO_3$. The resultant mixture is then ready for proceeding with the further operation of burning.

In the cement-making districts of Rugby and Wales, we have the well-known Lias formation of limestone and shale, and this is successfully treated for the manufacture of Portland cement. The thin layers of these materials with their variation in composition must, similarly, be very accurately and efficiently dealt with. In working the Lias formation it is found that the preponderance of shale in proportion to limestone (which is generally found to contain 78 to 85 per cent. of carbonate of lime) renders the cost of working heavy, because of the removal of surplus clayey material not required in the manufacture. This Lias formation consists of layers of impure limestone of varying thickness, ranging from two inches to two feet and parted by means of shale and clay, the total thickness of shale beds considerably exceeding, as a rule, that of the limestone, which necessitates removal and tipping the waste.

On the Tyne, Wear and Tees, and in the north of England generally, Portland cement is manufactured from chalk imported from the Thames, Medway or Sussex districts, and this is mixed with a local clay found on the site of the works. From this mixture a good quality cement is manufactured.

These descriptions, then, deal with the most important deposits of cement raw materials over the country.

In the United States most of the cement produced is from the Lehigh Valley argillaceous limestone, a sample of which we have here, and which contains rather more clay than is required for a correct mixture. To this a small amount of pure limestone, usually 10 to 20 per cent., is added to bring the mixture up to the necessary percentage of calcium carbonate required in the manufacture.

In Germany the raw material consists of chalk marl, similar to the samples we have before us.

It will thus be seen that, given chalk and clay in approximate proportions of three to one, or lime with silica and alumina in any other form, it is of the first importance that these materials shall be treated with a full knowledge of the all-important chemical and mechanical operations of combining them, which alone can secure the manufacture of a reliable product.

Now I must refer to the mixing processes by which these raw materials are brought to the condition for chemical combination, and if attention is paid to these diagrammatic sketches of the processes of manufacture my explanations will be more clear to you.

The preliminary mechanical blending of the raw materials for the manufacture of Portland cement is a stage requiring the utmost technical skill, for the thoroughness of the process primarily determines the quality of the resulting cement, and if the manufacturer is to turn out a product of reliable quality the scientific supervision of this branch of the manufacture is of paramount importance.

The primary conditions of any method of Portland cement manufacture are that the raw materials shall be (1) correctly proportioned, (2) very finely comminuted, and (3) thoroughly mixed. The proportions of chalk and clay must be kept to a standard as closely as possible, and this at the present time, in the most successful cement works, is carried out under the supervision of the works' chemists. It is firstly essential that extreme care should be exercised in obtaining the correct proportions of the chalk and clay, or whatever other raw materials may be used in the process, so that the resultant mixture may be relied upon to contain the exact chemical constituents necessary for the manufacture of a thoroughly sound cement; for if the raw materials are not mixed in this proper proportion, nothing can be done later to correct it, and the result will be an inferior product. The proportioning of the ingredients is governed by continuous laboratory checking of the raw materials as they are quarried, and this testing by the works' chemists goes on night and day, or as long as the manufacture is proceeding

The question how the next preliminary condition of the manufacture can best be fulfilled —that of the reduction of the raw materials— depends chiefly upon their character, so that the details of the methods adopted by manufacturers for grinding generally vary with the raw materials used.

Upon referring to the diagrammatic sketches I have here, and by following them with my descriptions of cement manufacture, it will be seen that there are two principal methods of reducing and mixing the raw materials, namely: Firstly, the "Wet Process," applicable only to soft materials, the correct quantities of the raw ingredients being ground and mixed with the aid of a considerable amount of water; secondly,

the "Dry Process," in which the perfectly dry materials are ground together to an impalpable powder or "flour," and subsequently mixed to correct chemical proportions.

The wet process of mixing the raw materials is particularly adapted to such materials as are easily disintegrated by the addition of water. This method of mixing, as originated and developed in this country, is employed to a considerable extent by the manufacturers of cement on the Thames and Medway—the seat of the industry. By this process the chalk, as quarried, and clay are weighed into what is called a "wash-mill," where a large amount of water is added. The wash-mill is simply a brick pit, some 15 feet in diameter and 5 feet deep, in which revolves a series of harrows for breaking up and mixing the two ingredients in their wet state. It is fitted with a circular framework revolving on a central pier, to which the harrows are suspended by chains, the machine being driven by a crown wheel which drives the heavy harrows round the wash-mill and through the material at the same time, thus agitating the mass and disintegrating and mixing the raw materials so as to bring the mixture to about the consistency of cream. In this condition it is termed "slip" or "slurry."

The thick liquid material from the wash-mill is then pumped to further grinding machinery in the shape of mill-stones or tube-mills, where the operation of amalgamation of the raw materials is completed.

The tube-mill as used for wet grinding consists of a drum (about 20 feet long and 4 feet 6 inches diameter) made of steel and protected against wear and tear by renewable cast-iron plates. The drum contains a large number of flint stones, and its interior is easy of access through two or more manholes.

The raw mixture, previously reduced by the wash-mill, flows through a simple straight pipe and through the hollow journal on to the front end near the gearing into the grinding drum, which slowly revolves. After being thoroughly ground by the flint stones, the material is discharged through the hollow journal at the opposite end into a trough, which conducts the mixed materials to the drying chambers.

In the dry process method of dealing with the raw materials for cement manufacture, the calcareous and argillaceous materials, of whatever substances they may be composed, have first to be dried after passing the preliminary crushing machinery. The dryers often take the shape of extensively constructed brickwork kilns, but with the more general adoption of the dry process of manufacture little time was lost in inventing a less costly and more efficient plant which could also be worked at a much reduced labour cost. The dryers now usually employed, therefore, in the most modern plants, consist of revolving cylinders some thirty to fifty feet in length and about four feet in diameter. These rotary drying drums, as they are termed, are supported on steel tyres resting on heavy friction rolls, and the drums are rotated, when in use, at a speed approximating two revolutions per minute, and are usually set with an inclination of about one half-inch per foot.

The raw materials, after passing the crushing rolls, are introduced into the upper end of the dryers and are immediately caught by cascading channels fitted inside the drums, which lift and drop the crushed raw materials as the drum revolves, and present them to the hot gases passing through the drums in the opposite direction to the way the materials are travelling, to the lower or outlet end. The use of the waste heat from the kilns is thus employed for drying purposes, or, again, furnaces are sometimes arranged to rotary dryers for the external heating of the drum.

The raw material, after being crushed and dried, must then be reduced to an extremely fine powder or "flour," and then carefully and thoroughly mixed to the proper chemical proportions before being conveyed to the kilns for burning. The plant usually employed for dry raw material grinding is often exactly the same as that used for grinding the finished cement, which I will describe later.

This dry process of manufacture is generally employed where the raw materials cannot be satisfactorily reduced by the addition of water. It is adopted in the Rugby and Wales districts, and in the Cambridge district also.

In America and Canada the dry process is generally adopted, and similarly in Germany the dry process of manufacture is considered a less costly process than the wet method.

It will be seen, therefore, that in preparing the raw materials for the manufacture of cement, the chalk and clay must first be reduced to the utmost fineness, either by the addition of water or by dry grinding, either of which processes breaks down the cohesion between the particles and leaves the material in a very finely-divided state, the physical properties of the respective materials to be dealt with generally determining which method of reduction is to adopted.

Now, before the prepared raw materials pass to the next stage in the manufacture—that of burning—the composition of the raw material mixture is ascertained by analyses and tests, and the carbonate of lime (familiarly known by its chemical formula, $CaCO_3$) should be kept within, at most one-half per cent. of the quantity found to produce the best cement. This percentage of lime varies in different works according to the many geological formations contributing to the manufacture, but, roughly, a combination of 75 per cent. of chalk and 25 per cent. of clay, will produce a cement of good quality. If any carelessness is permitted in the mixing process, the results are likely to be disappointing, for when the proportion of clay runs too high (or the percentage of lime carbonate falls below 75) a compound is obtained which, in the burning process, will fuse at a temperature lower than that required for the production of sound clinker, thus rendering it useless; and, on the other hand, an excess of chalk (above, say, 76 per cent.) will allow a mixture to sustain the highest temperature in the kiln without risk of fusion, but the resultant clinker would be of doubtful quality because of its expansive tendencies when ground for cement.

Again, a variation in the amount of carbonate of lime, even to one-half per cent., is found to alter appreciably the tensile strength of a cement, high lime producing high strains, and low lime, low strains.

The chemically-mixed raw material prepared in ordinary course of manufacture may, therefore, analyse in this way:—

Silica	16·5	Clay
Alumina and Oxide of Iron	6·5	
Undetermined	0·5	
Carbonate of Lime	75·5	Chalk
Carbonate of Magnesia	1·0	

From such a material, if properly treated in the further stages of manufacture, a good commercial cement, testing at least 600 lbs. per square inch in seven days, should be produced. The raw materials after combination are then carefully mixed and proved before proceeding with the manufacture.

The next stage in the manufacture of Portland cement, following the scientific and mechanical preparation of the raw material, is that of burning at a high temperature, or calcining, the raw product at a point of slight vitrifaction, resulting in what is commonly called a cement "clinker."

As will be seen from my previous remarks, Portland cement consists of a chemical combination of lime, silica, and alumina, and these materials are combined together under the action of great heat, thus becoming a mixture of silicates and aluminates of lime. The resultant material is ground to a fine impalpable powder, after which the product is ready for the market.

In the raw materials it will be observed that the carbonate of lime, silica, and alumina, are in an uncombined state; in the conversion of the prepared raw materials into cement clinker by burning, the silica and alumina of the clay immediately enter into combination with the lime, thus forming calcium silicates and aluminates.

These compounds are the important constituents of a Portland cement, and give to it, when combined in their proper proportions, its hydraulic properties. None of the cements of commerce, however, are made up wholly of these three ingredients, for the raw materials from which cement is made are never quite pure. It has been found, for instance, that iron oxide behaved in burning a mixture just as alumina, and that a good cement could be made in which all the alumina was replaced by iron oxide; but the essential elements of a good cement are that it shall contain at least the necessary amount of silica and lime.

The calcining process is a purely chemical one, and it is a state of the manufacture involving great responsibility, for just as the primary blending of the chalk and clay or faulty mixing can make or mar the quality of the cement, so can the burning of the material destroy all that is valuable in the finished product. If the temperature is too high in the kiln, the resultant material loses much of its value as a cement; and, on the other hand, if the heat be not sufficient, the necessary chemical changes do not take place, and a similar unsatisfactory result is obtained.

The proper degree of burning is indicated by the formation of a dense greenish-black clinker when coming from the kilns. Light-burned clinker is brownish and soft, while over-burned clinker is fused and slag-like.

The aggregate temperature in the process of calcination shows that, for normal Portland cement burning, a heat is required in the kiln amounting to 1,400° C., or 2,500° F. This temperature is variable, according to the percentage of carbonate of lime contained in the raw materials, the higher the proportion of lime the higher the temperature which is

necessary to produce complete diffusion in combination with silica.

The kilns for burning the raw materials are always constructed for either an "intermittent" or a "continuous" process. The intermittent kilns now generally adopted are those employed in the wet process, and are of such a design that the burning necessitates a distinct loading and drawing operation, giving intermittent working and demanding the shutting down of the kiln during the drawing operation. Since this method of manufacture is one that will soon be discarded, I will not devote any of your time to an explanation of this kiln.

But in the continuous kilns, the burning of the raw material proceeds without a break, and the drawing of the clinker takes place at the same time without interruption, thus making a continuous process.

Continuous kilns are generally costly to construct and require skilled labour for their operation. These kilns are economical in fuel, and where they are used the calcining process is much more regular and the cement is of better quality.

In the category of continuous kilns we come to the process of burning by the rotary kiln which has been lately brought into use. The manufacture of cement by the rotary kiln may be said to have revolutionised the industry, and this method of burning the raw materials is perhaps the most scientific and practical invention that has been introduced into the manufacture since Portland cement was first known. Although the use of this kiln is a technical and expensive process, involving heavy capital outlay, and high cost of production and continual upkeep, yet a considerable time must elapse before any further development will arise to outclass this invention in the manufacture of Portland cement.

More than 90 per cent. of the cement manufactured in the States is produced by the rotary kiln, and in England there are numerous works in which the kiln is solely adopted. Its use in all directions is also daily increasing, and many other factories, not only in this country but in many parts of the Continent, are now installing the rotary kiln for cement burning.

Although perhaps a new method of cement manufacture, enough has been seen of the product made from the rotary kiln, both in science and practice, to declare it to be the product of the future. The rotary kiln consists of a slightly inclined steel or wrought-iron cylinder, usually from 100 to 150 feet in length, and 6 to 8 feet in diameter, and it is inclined to the horizontal at about 1 in 30. The kiln is lined with radial fire-bricks, some 9 inches in thickness, and the long cylinder is mounted on tyres running on rollers and slowly rotated by gearing.

The cement-making materials are continuously fed into the kiln through a pipe at the upper end, in the form of either liquid mud or dry powder, according to the process adopted in preparing and mixing the raw materials. Finely-ground coal is almost always used as fuel, and this is introduced into the lower or outlet end of the kiln by a jet of air issuing from a blast fan.

When the kiln is started the fine coal is ignited, and after a time a white heat is obtained in the lower end of the cylinder. The raw material is then fed into the kiln, and as it gradually descends into the zone of heat generated by the perfect combustion of the finely-ground coal fed into the cylinder from the opposite end, it parts with any carbonic gas, forms little rounded balls which reach nearly white heat in the lower third of the kiln, and finally issues at the lower end as well-burned clinker in grains about the size of a large pea. The greatest heat is naturally near the fuel-jet or outlet end of the kiln.

The operation of calcining is a continuous one, and with proper care under or over-burning may be avoided. The hot clinker from the kiln is cooled either by being elevated to cooling towers or by rotary cooling drums. The cooling drums now generally in use in this country are placed at the lower end of the kiln, and receive the hot clinker as it drops finally from the kiln and passes into the coolers. These generally consist of tubes some forty feet long and four feet in diameter, containing cascading channels for lifting and dropping the hot clinker as the coolers rotate, thus presenting it to the cold air drawn through the clinker by the fan discharging coal to the kilns. The coolers rotate at a somewhat higher speed than the furnace tube, and by the air for the latter being drawn through the red-hot clinker a fair proportion of the otherwise lost heat is retained and utilised. When the clinker issues from the coolers it is quite cold enough to handle, and to pass to the further process of grinding into powder.

But before this stage it is necessary to point out that all rotary kiln plants with ground-coal firing must include an apparatus for the drying of the coal to be used in the burning, and also a grinding plant to enable the coal to be finely pulverised before entering the kilns.

The most common design of coal drying consists of an inclined steel cylinder encased in brickwork. The hot gases from the fires of the coal-dryer coming first in contact with the cylinder at the point where the wet coal is introduced, pass along and around the tube on the way to the chimney-stack, which is located over the discharge end, whilst a separate chimney at the feed end of the rotary coal-dryer permits the steam from the moist coal to escape, and gives an outlet for any congregating gases or coal dust.

The wet coal is introduced at one end of the heated drying drum and by means of cascading channels inside, and the inclined cylinder slowly rotating the coal passes through the drum, and by the time it arrives at the outlet, the dried coal is quite suitable for the purposes of fine grinding for use in the rotary kiln.

From the dryer the coal falls into a conveyor, and is carried automatically to the coal-grinding mill, which contains machinery for reducing the slack coal to an impalpable flour. For the process of coal-grinding the usual ball and tube-mills or Griffin mills are required, and this plant is therefore similar to the clinker-grinding plant, particulars of which I will give you later. The finely-ground coal is then taken to the kiln-house, where it enters the coal-hoppers situate in front of each rotary kiln, and from these hoppers an automatic feed conveys the powdered coal to a point where it is met by the heated air-blast from the fan to the kiln. When reaching the heat of the kiln the powdered coal immediately bursts into flame, and the intense heat in the kiln is thus kept continuously regular.

The percentage of fuel used in burning a ton of cement by the rotary kiln is from 25 to 35, although this percentage varies considerably according to the quality of coal used and the fineness of grinding, and the facility with which the raw materials are burned.

A satisfactory coal for the rotary kiln is generally obtained from the various bituminous coals found in this country, but it is necessary to see that the percentage of ash in the coal does not exceed 10, and that the coal also has a value of some 7,000 calories per kilo, which is equal to 12,600 British thermal units per pound of coal.

We now come to the succeeding and final stage in the process, the grinding into an extremely fine powder of the clinker which comes from the kilns; and this process has exercised quite a large proportion of ingenuity during the past few years. So much attention has of late been devoted to the manufacture that, as regards the mixing of the raw materials in their due proportions and the proper calcination of the mixture so obtained, one brand of cement may be said to be very much like another, provided the works are suitably designed and the various details of the manufacture are carried out with care.

The question then arises—What constitutes a high-class cement? To this question the answer is, that the true test of quality is not to be found in the brand but in the fineness to which the cement is ground—always provided, of course, that the materials are carefully selected and the various stages of manufacture are properly carried out.

It is not intended, however, that I should deal with the scientific qualities of cement by grinding to various degrees of fineness. I propose now merely to deal with the machinery generally employed in the process of clinker reduction. It must be explained here, however, that in clinker-grinding not only is it necessary that a certain degree of fineness be attained to make a satisfactory quality of cement, but that also as large a proportion of "flour" as possible shall be contained in the finished product. By "flour" I mean that the cementitious property of the material is believed to reside principally in the extremely fine particles of cement, as apart from the "residue," which consists of practically inert material. These are terms which, as you know, are used in the testing of cement for fineness.

The first stage in the reduction of the clinker is generally carried out by an ordinary stone-breaker or crusher, or rolls, which reduce any large lumps to the size of about three-quarter-inch cubes down to coarse dust, and after this operation the clinker is conveyed to the fine-grinding machinery.

In modern works the preliminary grinding of cement clinker is carried out by the ball-mill, and from this mill the coarsely-ground material is conducted to a tube-mill which finishes the fine grinding previous to storing the cement. The ball-mill consists of a cylindrical grinding drum, mounted on a steel shaft running through it, and provided with a tightly closed sheet-iron casing. The grinding-drum is composed of overlapping steel grinding-plates, in one half of which holes are bored for the ground material to find its way through to the fine sieves externally surrounding the drum, and through which the somewhat coarsely-ground cement passes and is conveyed to the tube-mills for

finer grinding. The crushing action of the ball-mill is caused by the revolving of the drum, which contains a number of steel balls of various sizes between which the clinker is crushed and pulverised. This description will be clear to you when I am able to put some illustrations upon the screen.

For the finishing process—the fine-grinding proper—the tube-mill is employed, which grinds by means of the round flint stones contained within it. The tube-mill consists of a wrought-iron revolving cylinder with hollowed pivots at both the feed and delivery bearings, and is about one-half full of rounded flint stones. The coarsely-ground cement is fed from the ball-mill into one end of the tube-mill, and the rotary action of this mill, similarly to that of the ball-mill, finely pulverises the cement as it passes through the falling flint stones to the delivery end.

The finished cement is ground sufficiently fine to pass through a 76 × 76 mesh sieve with about 1 per cent. residue, and although finer grinding is rarely demanded, it can be readily accomplished by the manufacturer, if necessary; but this means a reduced output from the plant.

From the grinding mills the cement is conveyed into the stores, and after it has cooled down the material is ready for loading out at the factory.

As to the storage of Portland cement, it is generally considered that the longer the cement is kept in stock the more reliable it is to be found in use; but the modern product of to-day's manufacture requires neither storage nor aeration to provide and ensure the success of its quality.

With the product manufactured many years ago it may have been necessary to aerate cement for some considerable time before introducing it into the work, but with the cements manufactured to-day this is quite unnecessary. The aeration of cements is a safeguarding process adopted by engineers with important work, and was perhaps advisable to eliminate any "free lime" that might be contained in the material, as an underburnt or carelessly manufactured cement contained a considerable quantity. Cement such as this would, when mixed with water, set quickly, and sooner or later the particles of "free lime" absorb moisture and change from what is termed "quick lime" (CaO) to a hydrate of lime ($CaHO_2$), and the expansion which accompanies this change produces a disastrous effect in the hardened cement.

The old idea was, therefore, that if the cement were exposed to the atmosphere for some time before being used, any free lime which it might contain would absorb moisture from the atmosphere and would not then be liable to cause injury to the concrete after setting. But a cement made from accurately-mixed raw materials, well burnt and finely ground, as all good cements should be, will not require any aerating process, and as soon as the cement is manufactured it should withstand the recognised tests for quality immediately it is ground.

It is desirable, however, that the material should be cooled down before loading into bags, and therefore the manufacturer generally arranges that he has sufficient quantity of material in stock to provide that engineers are supplied with a perfectly cool cement for their work.

DISCUSSION.

The Chairman (Professor J. M. Thomson), in opening the discussion, confessed that the paper had taken rather a different line from that which he had expected. He had hoped to hear a little information on the chemistry of cement, particularly with regard to the rather mystical change which took place in its hardening. The present theory was still what it always was, that cement was a mixture of tri-calcic silicate and tri-calcic aluminate; but what happened to those constituents when water was added to them, and they subsequently hardened, was a question that men of science would like a little information about.

Mr. D. B. Butler said the author, in referring to the Newcastle works, had stated that chalk was carried to the northern port by colliers which brought coal to London. That statement was not as accurate as it might be, because the majority of the chalk which was carried north was conveyed in specially-designed barges, which were towed, and not in colliers. The impression made upon him by the author's remarks was that he rather decried English manufacturers for using the wet process as much as they did, because the Germans and the Americans used the dry process. Anyone who had to use a flinty chalk, such as was obtained in most instances in the Medway, would experience difficulty in using the dry process. The wet process with the wash-mill was by far the simplest method of treating such chalk, because the flints were in that way washed out almost automatically, whereas in a dry process the grinding of chalk with flint in it would introduce trouble.

Mr. J. F. Waycott said that although the author had referred to the processes adopted in America, Germany, the United Kingdom, and other countries, in the manufacture of cement, he had entirely ignored the cement produced from the Tournai Basin in Belgium. The author had stated

that good Portland cement was an intimate mixture of carbonate of lime, silica and alumina, and that, as a natural combination of those materials could not be found, it was necessary to adjust the compositions. Did the author know that in the basin of the Tournai in Belgium there was a natural rock combining most accurately practically all the constituents that were required for the manufacture of a perfect cement? Was he prepared to say that a rock which contained the requisite proportions of materials suitable for the manufacture of cement was not a Portland cement, but that Portland cement could only be made by the admixture of two materials such as chalk and clay, as was stated in the British Standard Specification? Personally, he contended that if a natural rock combined chemically all the desired constituents it should be considered a Portland cement. He was satisfied that geological formations could be found in this country corresponding to the Tournai rock which would produce a good useful cement, and he hoped English cement manufacturers would turn their attention to that subject.

Mr. Walter F. Reid, F.I.C., thought the last speaker was under a misapprehension with regard to the British Standard Specification for cement. That specification stated that the material must be an intimate mixture, but it did not say it must be an artificial mixture. If the materials could be found mixed in Nature it was an admixture. Similar deposits to those in Tournai were to be found in this country, and they had been used very largely for the making of cement; and from tests he had made of English and Belgian cements he had found that the former was not only equal, but a great deal superior, to much of the latter. The material in the Cambridge district was composed of a similar natural mixture, and the author had very clearly explained how uniformity was obtained from the natural layers in which the composition was not uniform by taking materials from different parts of the quarry and mixing them under the supervision of the chemist, so that the ultimate result was absolutely uniform. He was instrumental many years ago in starting a cement factory in the Rugby district, and no engineer worthy of the name now rejected a Rugby cement if it otherwise came up to the standard. When the first Rugby cement factory was started he analysed the whole of the layers, and found there were considerable differences in them, and ever since it had been necessary to mix the different layers of limestone in certain definite proportions. The layers were also full of fossils, and these were very often fossilised in the form of pyrites, which were sometimes very troublesome. They gave a great deal of sulphur in the cement, which formed a sulphate in setting; but the material was dug out so carefully that the Rugby cement was now second to none in the country. It was quite true that this country had learned a lot from Germany since Germany, in the first instance, learned the lesson from England. There were many instances in which England taught Germany her first lesson, and when that country had learned to spell she had written out whole treatises for the English to learn from afterwards. Of this the aniline dye industry and the cement industry were striking examples. It was amusing to look back on the form of testing employed in the old days, when in every cement factory there was a sampler, who took a certain quantity of slurry as it came from the wash-mills, put it into a little vat, stirred it up, and twice a day would make little cakes of it in a small drying-oven, which were then burned in a sample kiln, and subsequently powdered and tested. The samplers rather ridiculed the idea when he began to test cement by the carbonate of lime method; but when he showed them his results twenty-four hours before they could obtain any results at all, they saw there was something in his method, and the calcimeter had now been adopted as the controlling apparatus for the whole of the cement industry. The rotary kiln was adopted owing to the enormous economy in fuel combined with economy of labour that resulted from its use. It was worked out in the first instance in the United States because labour was very dear in that country, and the Americans made very large quantities of cement, but it was really an English invention. Ransome put up the first rotary kiln in this country. He did not know where the author had obtained his information with regard to the cement used in the Thames Tunnel; but personally he was always under the impression that it was what was called Roman cement, *i.e.*, burnt argillaceous nodules of London clay. When visiting the tunnel many years ago he noticed that considerable leakage was taking place, which was put down to the decomposition of the Roman cement. An engineer who was with him said that if Portland cement had been used it would not have happened. As a matter of fact, Roman cement was not so good. The statement made by Mr. Davis that clay was dredged up from the bottom of the river was not the case. The mud in the Thames valley that was used for the purposes of cement had been deposited in mud flats, which formed the blue mud used in cement-making. If the mud was taken out of the bed of the river itself he believed that a considerable amount of sand would be found in it which would render it unfit for the purpose of cement-making. Dredgers were used because it was found that it was an economical process to dredge the mud up out of the clay-pits instead of having to take the water out and dig it by hand. The author had also made the very general statement that limestone was used in the United States for making cement. As a matter of fact, a great variety of materials was used in that country. Personally, he had examined at least half-a-dozen, and they were not all limestone; some of them were real chalk, like English chalk. The statement made that only marl was used in Germany was not correct either. There was a big district in Germany, in

the neighbourhood of Oppeln in Silesia, where marl was used, but the great factories in the north of Germany used clay and chalk just as the English makers did. The accuracy with which the manufacture was carried on, as explained by the author, was really marvellous compared with the old manufacture. Manufacturers now worked to within one-half per cent., whereas a 4 or 5 per cent. variation was quite usual in old days. Personally, he thought it was unnecessary to aerate cement at the present time; but in earlier days, when the main-drainage scheme of London was started, Mr. John Grant, the assistant engineer of the Board of Works, specified that all the cement should be aerated. The fineness then specified was something extremely coarse compared with what was now required in a standard article. There was no doubt whatever that the extremely fine grinding now adopted had given an enormous impetus to the use of cement. The finer cement could be ground, the more cement would be sold. Cement could now be used for a hundred purposes to every one to which it was put when it was first adopted. In the beginning it was a hydraulic mortar, and nobody would rely on it for the main bulk of the structure. Bazalgette, the constructor of the Embankment, looked upon the use of cement as a hazardous experiment; but nowadays piles and pit-props, and all sorts of things were being constructed with it. It was a matter of very considerable importance, because wood was getting scarce, and the use of concrete in that direction should be considerably extended.

Mr. S. G. Robinson said there was an excellent reason for the almost exclusive use of the wet process on the Thames and the Medway, because it was found that not only could hard materials be ground more cheaply by using the tube method, but the intimate mixture of the raw material was much more easily obtained when slurry was used than could be secured with a dry powder.

Mr. A. C. Davis, in reply to the Chairman's question, said that the chemistry or crystallisation of the setting of cement was a feature of the manufacture that was extremely obscure. During the past six months he had inspected many factories in the United States, and on asking an eminent expert what his opinion was on the crystallisation, technology, or chemistry of the setting of cement, he received the reply that it was a subject upon which he knew nothing. No one could give any information upon it. The setting of Portland cement was no more understood than the setting of plaster of Paris. It was known that there was a mixture of silicates, aluminates and lime, but what happened when water was added to those crystals and the cement set was at the present time purely a matter of conjecture. The statements he had made with regard to coal vessels carrying chalk from the Thames and Medway district to the northern cement-makers, to which Mr. Butler had referred, applied only to the original arrangements made by the manufacturers in the north. Mr. Butler was quite correct in stating that at the present time special barges carried the chalk from the south to the north. The wet process was more particularly adopted on the Thames and Medway on account of the flints which were contained in the chalk, and those flints could only be taken out by mixing the chalk and clay with an excess of water so that the flints were precipitated. He did not include the Belgian cement in his paper, because the bulk of the material produced in Belgium was termed a "natural" cement, which was produced by merely quarrying the raw materials and burning them as they were quarried. He joined issue with Mr. Waycott's statement that a material existed in Belgium which, when quarried, put into the kiln and burnt, would make either a Portland cement or a cement as satisfactory as any artificial process of mixing. His experience of the deposits in Tournai was that the materials varied considerably in the percentage of lime they contained. He went over one factory in Tournai recently in which the percentage of lime varied from 72 to 82 per cent. As he had pointed out in his paper, it was essential to keep the chemical combination of the raw materials perfectly accurate or within a half or one quarter per cent. of the necessary standard to produce a good cement. Any material which varied from 2 to 10 per cent. in calcium carbonate could not be relied upon to produce a thoroughly good cement, unless the raw materials were mixed together, and a standard of composition was obtained. He did not think it was a fact that a geological formation was available in Belgium which had a perfectly uniform composition. His experience of Belgium was that no such deposit existed. If Mr. Waycott could prove that such a deposit did exist, and that a material could be obtained in Belgium that remained constant up to one-half per cent. in its calcium carbonate value, that material would produce as good a Portland cement as any that could be made by artificial means; but he had investigated the Tournai district, and was not prepared to believe that such a deposit existed. Mr. Reid had commented on the statement made in the paper that limestone was chiefly used in America. As a matter of fact, in the centre of the industry, in the Lehigh Valley district, where the bulk of the cement in the States was produced, a hard limestone was employed in its manufacture; but in America, as in every other country, cement was made from various materials. There was no doubt that marl was used in Germany, but a number of other materials were also employed. The shortness of the time at his disposal prevented him from referring to the subject in greater detail. He was glad Mr. Reid agreed that the aeration of cement was hardly necessary under the scientific process of manufacture at present adopted, and it was interesting to hear how the science of the manufacture of the product

had improved during the past decade. Mr. Robinson had stated that a better mixture could be obtained by a wet process than by a dry, but personally he was doubtful on that point. He thought that no better mixture of the raw materials could be obtained than by mixing them when they were perfectly dry; and it would be seen in the near future whether Mr. Robinson's forecast, that the wet method would supersede the dry, was a true forecast or not. At any rate, it was impossible to get away from the fact that the better part of the cement made in Germany, and practically the whole of the cement made in the United States and Canada, was produced by the dry process.

On the motion of the CHAIRMAN, a hearty vote of thanks was accorded to Mr. Davis for his interesting paper, and the meeting terminated.

THE RUBBER INDUSTRY IN PORTUGUESE EAST AFRICA.

While the natural resources of the province of Mozambique are but slightly developed, rubber has been exploited commercially for over half a century, and the possibilities of its development into a great source of revenue have become probabilities during the last few months. From Lourenço Marques, at the extreme south, to Ibo, at the northern extremity of Portuguese East Africa, landolphia of various species grows in profusion. This plant is extensively exploited from Inhambane, Beira, Quelimane, Moma, Angoche, and Ibo, the last three through the town and island of Mozambique. South of the Zambezi the landolphia is a vine, sometimes of great length, and, when permitted, it attains the thickness of a man's arm. This vine, Landolphia Kirkii, according to the American Consul at Lourenço Marques, is considered rubber-bearing when it reaches half an inch in diameter, and is tapped by a series of long cuts. The flow is more abundant at the end of the rainy season, and, owing to the great difficulty of getting at the vines, whose habitat is naturally the forests, they are tapped but once a year, and then bled for all there is in them. This rapidly reduces the output of a forest, and, where supervision of the natives is impossible, the percentage of vines utterly destroyed yearly is very great. Where the rubber is collected by organised companies, steps are being taken to restock the depleted forests, which is not difficult. The landolphia grows well from a slip, and, before the rubber-gathering season opens, men are sent through the forests and plant two slips to every tree that has no vine at its roots. This method of saving a forest, however, only benefits permanent holders or the State, as it takes landolphia from five to ten years to reach a stage in which it is fit for tapping. Outside the territory covered by the Mozambique and Buzi companies, the collection of rubber, whether south or north of the Zambezi, is entirely in the hands of natives who collect and sell it to the Indians at the coast. At Inhambane the rubber seems to be collected with much care, and compares well with what is known as Beira rubber, except that it is not brought in in balls but in split lumps, the latex having been wound on a small stick, which is then cut out. North of the Zambezi, beginning at the Ligonha River, stretches the region whence comes what is known on the market as Mozambique rooty rubber. The best of this is that coming from the Matadane range, which lies between Moma and the Cocola River on the south, and Talalane and the Larde River on the north. Inferior qualities are gathered farther north, and their principal final exit is at Mozambique, the capital of the district. All Mozambique rooty rubber—and it must be remembered that the name applies only to rubber gathered north of the Zambezi—is marketed in a crude state, containing bark and rubber in almost equal quantities. This is due to the fact that the natives prefer to rip up the roots of the landolphia and beat out the latex contained in them. With a view to stopping this practice, the government established an export duty on root rubber. Owing to the fact that most rooty Mozambique rubber comes from unpacified regions, to which white people have not had access, little was known as to the species of landolphia prevalent in the district, and it was generally accepted that the species was the same as that worked by tapping south of the Zambezi. Recently, however, the American Consul succeeded in crossing the Matadane country, and much was learnt as to the rubber of the region which was not known before. In the first place, while the plant bearing the rubber is a landolphia, it is very different from the species known south of the Zambezi, and is essentially a root producer. The plant is not inevitably destroyed by pulling up the serviceable roots. The Matadane landolphia has an extensive root system, running near the surface, out of proportion to the plant itself. These roots send up shoots somewhat resembling the suckers of wild cherry. A small shoot about the size of a lead pencil often leads to a root two or three times as thick. The latex, which is rich in quantity and of very good quality, is found in the bark of the roots. The method of securing the rubber is crude, but it is the most sensible that could be applied by the natives under the circumstances. After ripping up a bundle of roots, the native beats off the bark, which is then put over a small fire and brought to a boil three times. The latex appears as a fine web through the bark. The mass of bark and rubber is taken out after each boiling and kneaded to separate the bark from the rubber. The final result is a small black ball, with a high percentage of bark particles still left in the rubber. In tearing up the rubber plant, the natives say that if only a small part of the root is left it soon springs up again. This is a most important point, as far as the ultimate wealth of the region is concerned, and evidence supports the statement, as several tests were made at villages where piles of rubber-plant refuse were seen before every hut, by sending out natives for fresh roots. The installation of

simple machinery for cleaning out the bark and eliminating the damaging boiling process will bring Matadane rubber into favour in the market. While no rubber from the Landolphia Kirkii was seen by the Consul, it must not be assumed, he states, that this species does not grow north of the Zambezi. A plant closely resembling it, but whose latex seemed a little weak, was noticed in profusion in the Matadane country, where the natives took little or no notice of it. There is little doubt, however, that this vine, or something very similar, is exploited as far north as Ibo. Besides the landolphia, an indigenous rubber-bearing tree, Mascarenhasia Elastica, has been discovered. It yields rubber of good quality, but it is difficult to tap on account of the fluted formation of the trunk; and, as it requires fifteen years to mature, it would be of little value as a plantation tree. The only plantation tree which has been largely exploited in the province of Mozambique is the ceara, of which over 10,000 exist, mostly in small plantations. Up to the end of 1909, these trees had proved a failure and were mostly abandoned; but the visit of an expert on rubber in March, 1910, has brought back confidence in the ceara tree, and preparations are under way for extensive and systematic planting. The ceara does well throughout a vast extent of the province, and reaches the tapping stage at the end of three years.

THE CHINESE LACQUER INDUSTRY.

The earliest record of lacquer is said to date from the Sung dynasty, although it probably existed long before that date, but in a more crude form. It was introduced into Japan in the third century from Korea, at the time of the conquest of that country. The seventeenth century marked great progress in the industry in Japan, and the gold lacquer became very popular, but from that time its popularity decreased, and the demand did not revive until the last few years. In China the manufacture of the lacquer ware, known to the Chinese as the "No. 1 Foochow lacquer," can hardly be called an art: it is rather a craft, the result of infinite labour and patience, since the laying on of the coat or colour requires no more skill than the simplest form of painting. The superiority of the No. 1 Foochow lacquer over all other forms is due to its durability and beauty; it takes more time to prepare (in some cases several years), and possesses a finish and depth of colour unlike any other products of the same nature. The extreme care taken to refine the pure lacquer, the number of coats given, and the great quantity of gold and silver leaf usually used in the last coat are the cause of this. Concerning the gold and silver leaf used, the former imparts to the lacquer a dull gold colour, in whose depth a fine gold powder may be discerned, and the latter gives a silver green effect. Sometimes a little colouring matter is added, but the result is supposed to be better without it. The lac, as is well known, is not a manufactured product, but the sap of the *Rhus Vernicifera*, or Ch'ishu of the Chinese. The tree is tapped at night during the summer season, and the lac sold to the consumer as a dried cake, or in a semi-fluid state. It is first placed in a rectangular pan, where it is continually stirred with a spatula for about two days, then pressed by twisting the lac through a sack made of fine grass cloth, and lined with a thick layer of cotton. The refined lac is put into the pan again for a day, and the same process is repeated. So prepared, the lac will answer for the first coats given to the articles, but for the final or colour coat the lac used undergoes this process four times. According to the American Vice-Consul at Foochow, the invention of the No. 1 lacquer is said to belong to the Shen-Shao-An family, in whose hands the manufacture still is. To this same family is also accredited the invention of silk lacquer. The term lacquer ware applies only to the thing which has undergone certain preparations before receiving several coats of lac. Ordinary woodwork covered with Ningpo varnish, or even with lac, is not included. The proper lacquer ware may be chiefly divided into two kinds, the ordinary and the silk. The ordinary lacquer is applicable to almost every kind of furniture and to ornamental articles for the houses, but is commonly applied to woodwork. Only very old wood, usually cedar, which will neither warp nor crack, is used for this purpose. Articles and ornaments of the most delicate carving are treated in this fashion. To prepare the woodwork, such as furniture, for lacquer, a lacquerer scrapes the wood one or two inches wide along any crack or joint or opening that may exist. It is then filled up with lac and two or three coats of linen cloth, which will not only cover the depth, but also serve to keep the parts together. After a fortnight or longer, when the lac on the linen is perfectly dry, the woodwork is covered with a thin coat of black lac, mixed with a little "ching-chu," a refined red clay. Ten days later a process of general polishing is applied to the article with fine pumice stone of various shapes and sizes. About every ten days a new thin coat of the lac mixture is put on. The article is always polished before receiving a new coat. After the ninth or tenth coat of this black lac mixture, the article is thoroughly polished so as to receive the colour coat. For the preparation of the final coat, a small portion of lacquer that has undergone the refining process four times is mixed by a pallet knife on a stone surface with the gold or gold and silver leaf. When thoroughly mixed, it is placed in the centre of a thin sheet of cotton paper. The paper is then rolled together, with the lacquer inside, the ends being twisted in opposite directions, until the lac oozes through. This is repeated three times. The silk lacquer is generally applied to small articles, either for practical use or for ornamental purposes, such as vases, card-cases, and images. The art is so far advanced, that images of almost every description can be made under this system with accuracy and clearness. The process commences by pasting a

coat of native printing paper, with rice glue mixed with ching-chu powder, on a well-modelled clay image, care being taken to cut the paper into proper sizes to suit the different parts when it is pasted, and to paste it so neatly that every wrinkle of the face, or fold of the material, should there be any, will remain clear cut. After the pasting the figure is thoroughly washed with this thin mixture, and left to dry for two or three days. On the top of the paper is then pasted the silk with a plaster of black lac and pulverised ching-chu, with still greater care as to the overlaps and folds than is required in the paper coating. Ten days later another coating of silk is added after the necessary polishing has been applied. For small articles only two coats of silk are necessary, but in the case of larger ones one or two more coats may be added. Before receiving the colour coat, the image is placed in water for such a length of time that the clay inside will dissolve and can be taken out through a hole left at the bottom of the figure for that purpose. After the removal of the clay the opening is sealed, and a fortnight later the hollow and exceedingly light article is ready to receive its decoration. On silk as well as on woodwork, the colour coat is applied but once. The lac, though black itself, can be made into almost every other colour existing, and of various shades, by mixing it with other ingredients. The most costly colours are those which contain the greatest quantity of gold dust, and the colours in most common use are bronze or ochre green of various shades, and purple or dark maroon gold. The term gold lacquer is easily misinterpreted to mean lacquer ware sprinkled with gold dust, or fragment of gold foil, or inlaid with gold thread, etc. In gold lacquer the gold or silver has been pulverised so fine that it appears no more as sprinkled dust, but its richness is blended with the other colouring matter and the refined lac, giving a lustrous and lovely tint of a uniform shade. A genuine No. 1 Foochow lacquer will stand any climate and any amount of washing, even with boiling water. In the common form of lacquer unrefined lac is used for the primary coating, and that for the colour coat has not been refined more than twice. Instead of ching-chu, which is comparatively expensive, the powder of broken bricks and tiles is freely used.

HOME INDUSTRIES.

Bad Yarn.—It is a feature of the present position of the Lancashire cotton trade that spinners who spin the better qualities of cotton—which does not necessarily mean the finer qualities—have felt the depression less than others. The present season's crop of American cotton is worse for spinning than usual, and it is said that many of the stocks that are now depressing the spinning trade are inferior to the normal production of the spinners who hold them. In the opinion of the *Cotton Factory Times*, the attempts to use such stocks are prejudicing the operative workers, and it seems that "numbers of instances can be found where the average earning of the weaving shed is less than it was when the uniform cost was 10 per cent. lower than it is to-day," although operatives in other sheds, where the quality of yarn is being maintained, are earning fair wages. The *Cotton Factory Times* hints that unless there is less of this inferior yarn, weavers will rebel against "the restraint of mill and joint rules which under normal conditions would be regarded as convenient and reasonable methods for adjusting disputes." It is deserving of note that many cotton operatives are emigrating. Bolton is a centre of both the spinning and the weaving trade, and it is said "as many as fifty per week of all descriptions of workers are leaving for Canada and other colonies." It cannot be lack of work that is inducing emigration, for one of the causes for the accumulation of yarn, and the consequent proposals for short time in the spinning industry, is the lack of weavers to work looms.

The Coal Mines Bill.—This Bill has been read in the House of Commons a second time after only two hours' debate, and notwithstanding the great complexity of the measure. That legislation is necessary for the better avoidance of accidents in mines is hardly open to doubt. From the beginning of mining statistics until five or six years ago, as was pointed out in these Notes recently, the percentage of fatal accidents amongst miners in Great Britain steadily fell; afterwards it was practically stationary for some years, but last year the total casualty list reached 1,620 lives, which is the largest number of deaths by accident since yearly statistics began. The total was of course greatly swollen by the disasters at Whitehaven, and Hulton Colliery, which had much to do with bringing home to Parliament the necessity for additional and more stringent regulations. The Bill now introduced by Mr. Churchill covers very wide ground, and it deals with the health and safety of upwards of a million persons, of whom 848,000 are employed underground. Most of the proposals are based on the recommendations of the Royal Commission, while others have been suggested by the mining experts of the Home Office, and others again by inquiries into the causes of the recent accidents. Everything except check-weighing and the eight-hour day is covered by the Bill, and the two exceptions have been dealt with in recent legislation. The provision making it compulsory for miners to wash may seem fantastic, but the main provisions of the Bill appear to be approved alike by the representatives of the owners and men. The Bill amends and consolidates the law relating to coal mines, including a certain number of enactments which will now be repealed, from the Coal Mines Regulation Act of 1887 down to the short Act for the better provision for rescue apparatus passed last year, and adds to the contents of these, while it consolidates a large number of fresh provisions for the prevention of danger, accident, and disease. Accidents in the shaft through over-

winding and breakages of rope, in the haulage way, through tubs leaving the track, or from falls, deaths from diseases, such as fibroid phthisis, induced in dusty atmospheres, are covered by the Bill. It also prohibits working in sections where the presence of gas rises above 2½ per cent.; the duties of foremen and deputies are more carefully safeguarded; provisions are laid down more stringently than ever as to safety-lamps; an attempt is made to grapple with the dust problem; and there are for the first time regulations for the provision of separate travelling roads in all new mines, and their construction in old ones where the authorities deem it necessary. Among the valuable provisions of the Bill are those for the erection of rescue stations and the right of search for matches. It may be regretted that the Bill contains no provision to prevent women pulling tubs or kans about pit banks, or for prohibiting the employment of girls on pit banks; the pit pony, too, is forgotten. It is also to be regretted that there has been no adequate debate on the Bill, either on introduction or second reading, but ample time is promised for deliberation in the subsequent stages. The Bill is not to come before the Grand Committee until after Easter, and in the interval there are to be conferences between the owners and the men, so that as far as possible the provisions of the Bill may take final shape as the result of mutual agreement.

Aid to Cotton Growing.—Early last year it was proposed that the operatives employed in cotton mills should make a contribution of one penny per month for a period of fifteen months to the funds of the British Cotton-Growing Association, for the purpose of helping in the completion of the capital of £500,000 required by the Association for the carrying out of the efforts to enlarge the area of our cotton supply. The annual report of the Amalgamated Association of Operative Cotton-Spinners just issued refers to the matter as follows:—"The proposal was made consequent upon an undertaking by the Employers' Federation to get their members to contribute an additional £72,000 to the cotton-growing funds. The penny per month was estimated to aggregate to about £30,000, which was considered to be a fair proportion to come from the operatives in addition to their previous subscriptions. In common with other operatives' associations, the proposal was taken up by our Amalgamation, and our members have willingly paid their quota when the collections have been taken. The amount realised from these monthly collections up to the present is short of £12,000. It is hoped the collections will be continued until the whole of the £30,000 is raised, whether it takes fifteen months or longer. As time goes on, the work being done by the British Cotton-Growing Association is shown to be more and more necessary, and the need for its further extension becomes increasingly apparent. Until the sources from which our cotton supply is drawn are numerous enough and extensive enough to enable the trade to cease to be almost entirely dependent upon any single country, as it is at present, we shall continue to have these periods of scarcity, with the attendant speculation and cornering which work so detrimentally to the interests of all engaged in the industrial departments of the trade."

The Potteries Dispute.—There is trouble among employers and employed in the Potteries. The operatives desire the abolition of the apprentice system, so far as it permits the apprenticeship of persons over twenty-one years of age. It is alleged that there are hundreds of the older men who are compelled practically to enter into private contracts with their employers to do piecework at a lower rate than standard. These men are, it is said, termed apprentices, and it has been known to happen that a young man has been working as a full journeyman while his father was an apprentice. Then the men are asking for the abolition of the "good-from-oven" rule, which requires that any article made by an operative shall be delivered in good condition to the employer, after it has been through the baking ovens, before the potter can be credited with it in his wages. The contention of the workmen is that if an article which is properly made is spoiled in the oven they shall still be paid for it. Beyond these proposals the men demand a general advance in wages. In the general earthenware trade they are asking for a 10 per cent. advance. The sanitary trade pressers, who had a 15 per cent. reduction two years ago, are asking for a 7½ per cent. advance. The teapot-makers want an advance of something like 25 per cent., claiming to justify it by changed conditions in their industry. The National Amalgamated Society of Male and Female Pottery Workers has about 4,500 members; the other two, the oven-men and kiln-men, and the packers, are understood to have only about 500 between them. Altogether the three unions have only about 5,000 members, and a rough calculation gives the number of operatives in the pottery district as something between fifty-five and fifty-eight thousand. The workers in the higher class of ware, who are half of the total number of operatives, are practically unaffected by the present dispute, but the processes of pottery manufacture are so highly specialised that they are largely dependent upon each other, so that a strike would concern not only those operatives who give in their notice, but many others who work alongside them.

A State Agricultural Bank.—Details as to the Government's scheme for a State Agricultural Bank are beginning to leak out. It is understood that a leading feature will be that the bank shall lend money to farmers at one half per cent. over Bank rate on condition of being allowed to audit the borrowers' accounts. But it is objected that this condition as to audit will prevent many farmers from applying for loans. Solvent men will not care to submit their affairs to State

inspection, and the much more numerous class of insolvents will know that application for assistance would be fruitless. Reference may be made in this connection to the experience of Belgium. In order to help the larger farmers, the Government in 1884 passed a law which led to the creation of a number of institutions known as *Comptoirs agricoles*, or agricultural banks. Each of these institutions consists of three, four, or five persons, who negotiate loans to farmers. They provide no capital themselves, but borrow all they require from the National Savings Bank, giving to that institution their personal guarantee for the repayment of the money, and receiving in return one-fifth of the interest charged to the borrower. At the end of 1907 there were eleven *Comptoirs agricoles*, with 2,755 loans actually running, the total amount of which came to £425,925. For very small farmers and peasant cultivators there are the Raffeisen banks. In 1907, 3,626 loans were granted, nearly one-half of them for sums less than £10. These loans are used for the purchase of cows, for the purchase, construction, or repair of houses, for trading capital, for setting young couples up in their homes, for the purchase of land, for the *paiement de soulte*, or the division of a property—that is to say, the sum payable in cash by any heir who has received more than his fair share of landed property on the division of an estate—for the purchase of a horse, for the repayment of debts contracted at usurious interest, and for various other objects. The regular rate of interest charged to borrowers is 4 per cent., while 3 per cent. is allowed on money left on deposit. The difference, less a small deduction for expenses of management, goes to a reserve fund. Although these banks have no capital, and although the reserve fund is not very great, there has never been a single case in Belgium of the failure of such a bank. With the growth of peasant proprietorship in this country the need for some such banks is becoming pressing.

GENERAL NOTES.

The Exhibition at Rome.—The exhibition at Rome, unlike most previous exhibitions in other places, is not confined to a restricted area, but extends from one extremity of the city to the other. It illustrates the three periods in the life of Rome, namely, ancient, Papal and modern times. The first section extends from the Capitol to the Appian Way, so that the visitor, after passing the Forum, the Coliseum, and other monuments of the past, reaches the Thermæ of Diocletian where the archæological exhibition is held. The history of Rome under the Popes and during the Renaissance periods is written everywhere; the churches, palaces, fountains, etc., all bear witness to the grandeur of that period which inspired such men as Michael Angelo to conceive such monuments as the cathedral of St. Peter's. The exhibition of Italian Art during the Middle Ages and Renaissance is held in the Castle St. Angelo, once palace, prison, and fortress; here the apartments of the Popes, as they were during the fifteenth and sixteenth centuries, are seen sumptuously furnished, with priceless furniture and collections of works of art. On the boundary of the modern city and extending beyond the Villa Borghese, and surrounded by the buildings constructed by the various nations who are taking part in the exhibition, is the beautiful gallery built to contain the works of living Italian painters and sculptors. This building is intended to remain afterwards as a permanent gallery of modern art. Crossing the Tiber by the fine new bridge, we reach the group of buildings in which are held the Artistic and Ethnological Exhibitions, and the Exhibition of Music and Dramatic Art. Reproductions of many of the most notable buildings in the various regions of Italy illustrate the different styles of architecture. Here the various dialects, folk-songs, etc., may be heard, and the characteristic dances of the country and the dresses and customs of the people observed. Festivals, competitions of every kind, and aviation meetings are being organised; whilst upwards of fifty congresses on a great variety of subjects will be held in a building specially constructed for the purpose near the Castle St. Angelo.

Cotton-growing in the West Indies.—It is disappointing to find that from various causes the cotton industry in the Leeward Islands received a check last year. In his report on the Blue Book of the Leeward Islands just issued, Mr. H. E. W. Grant, the Colonial Secretary, directs attention to this check, which he attributes partly to low prices and partly to bad weather and heat. Blister mite was very prevalent and adversely affected the crop, whilst the unwise habit of leaving old cotton bushes on the land greatly aggravates the evil. Fortunately the islands have hitherto escaped serious visitation from the cotton worm. In the Virgin Islands there remain large numbers of cotton plants of an inferior type, and the Government is doing what it can to persuade the planters not to use the local seed for planting but to import it. In Antigua the acreage under cotton has been decreased owing to losses sustained from the attacks of the "Flower-bud maggot," and in St. Kitts only 1,100 acres were planted owing probably to the fall in prices in the previous year. From Nevis and Montserrat the returns are more satisfactory, but the exports of cotton from the Leeward Islands are never likely to be large.

Stock Breeding in Siberia.—The most important industry in the Transbaikal Province is stock breeding. Cattle, horses, and sheep predominate, although a limited number of camels, deer, goats, and swine are bred. The horses average between twelve and thirteen hands high, and can draw a load of over one thousand pounds; and if driven in a troika (three horses harnessed abreast) they can cover thirty to forty miles a day. Journeys

of thousands of miles, at an average rate of forty miles a day, have been made by riding these animals. The horses are kept in the open throughout the year, and in winter they find their food under the snow. Some improvement has been made in breeding these horses, and only recently Arab blood was introduced. The cattle are of Mongolian origin, and are inferior and very small. They live in the same manner as the horses, and it is remarkable how they can withstand the severe climate and lack of food.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock :—

March 29.—George B. Heming, "Art Education in the Jewelry, Goldsmithing and Allied Trades." Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., will preside.

April 5.—Henry L. Heathcote, B.Sc., "Wheels, Ancient and Modern, and their Manufacture."

Indian Section.

Thursday afternoons, at 4.30 o'clock :—

April 27.—Sir Thomas Henry Holland, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord Avebury, D.C.L., LL.D., F.R.S., will preside.

May 25.—W. R. H. Merk, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock :—

April 4.—Captain R. Muirhead Collins, R.N., C.M.G., Official Secretary in Great Britain for the Commonwealth of Australia, "The Commonwealth of Australia." The Right Hon. Lord Denman, K.C.V.O., Governor-General Designate of Australia, will preside.

May 9.—F. Williams Taylor, "Canada and Canadian Banking."

Cantor Lectures.

Monday Evenings, at 8 o'clock :—

Professor J. A. Fleming, M.A., D.Sc., F.R.S., "Applications of Electric Heating." Four Lectures.

Syllabus.

Lecture IV.—March 27.—"The Domestic Applications of Electric Heating." Electric Water Heating—Its Cost and Economy—Air Heating by Electric Radiators and Convectors — Electric Cooking—Various Systems and Types of Utensil critically discussed—The Advantages and Drawbacks in Comparison with other Methods of Culinary Heating.

Alfred E. H. Tutton, M.A., D.Sc., F.R.S., "Rock Crystal : its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

Dates to be hereafter announced :—

Frank M. Andrews, "Architecture in America."

Professor Raoul Pictet, "Les Basses Températures."

Sir William Abney, K.C.B., D.C.L., D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

Hal Williams, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

Noel Heaton, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

MEETINGS FOR THE ENSUING WEEK.

Monday, March 27...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Professor J. A. Fleming, "Applications of Electric Heating." (Lecture IV.)

Geographical, Burlington-gardens, W., 8.30 p.m. Mr. H. J. Mackinder, "The New Geography: its Aims and Methods."

Actuaries, Staples Inn Hall, Holborn, W.C., 5 p.m. Mr. G. W. Richmond, "State Insurance against Invalidity and Old Age—the Actuarial Basis of the Austrian Method."

Tuesday, March 28...Association for Befriending Boys, at the Royal Society of Arts, John-street, Adelphi, W.C., 4 p.m. Annual General Meeting.

Cold Storage and Ice Association, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. M. Aurel Stein, "Explorations of Ancient Desert Sites in Central Asia." (Lecture II.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. Philip Dawson's paper "The Electrification of a Portion of the Suburban System of the London, Brighton and South Coast Railway." 2. Mr. J. W. Smith, "The Improvement of Highways to Meet Modern Conditions of Traffic." 3. Mr. H. P. Maybury, "Recent Development in Road-Traffic, Road-Construction and Mainten nce."

Photographic, 35, Russell-square, W.C., 8 p.m. Messrs. J. S. Dow and V. H. Mackinney, "Surface Brightness, its Measurement and its Application to Photography."

Wednesday, March 29...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. George B. Heming, "Art Education in the Jewelry, Goldsmithing, and Allied Trades."

United Service Institution, Whitehall, S.W., 3 p.m. Lieut.-General Sir R. S. S. Baden-Powell, "Boy Scouts."

Thursday, March 30...Antiquaries, Burlington House, W. 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. A. Bone, "Surface Combustion and its Industrial Applications." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. H. E. Corke, "100 English Wild Flowers, with Autochromes."

Friday, March 31...Society of Authors, at the Royal Society of Arts, John-street, Adelphi, W.C., 3.30 p.m.

Aeronautical, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Annual Meeting.

Royal Institution, Albemarle-street, W., 9 p.m. Professor H. S. Hele-Shaw, "Travelling at High Speeds on the Surface of the Earth and Above it."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. J. Swinburne, "The Uses of Chemistry in Engineering." (Lecture II.)

Saturday, April 1...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Radiant Energy and Matter." (Lecture V.)

Journal of the Royal Society of Arts.

No. 3,045. VOL. LIX.

FRIDAY, MARCH 31, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

TUESDAY, APRIL 4th, 4.30 p.m. (Colonial Section.) Captain R. MUIRHEAD COLLINS, R.N., C.M.G., Official Secretary in Great Britain for the Commonwealth of Australia, "The Commonwealth of Australia." The Right Hon. Lord DENMAN, K.C.V.O., Governor-General Designate of Australia, will preside.

WEDNESDAY, APRIL 5th, 8 p.m. (Ordinary Meeting.) HENRY L. HEATHCOTE, B.Sc., "Wheels, Ancient and Modern, and their Manufacture." The Hon. RICHARD CLERE PARSONS, M.A., Vice-President of the Society, will preside.

CANTOR LECTURE.

On Monday Evening, March 27th, Professor J. A. FLEMING, M.A., D.Sc., F.R.S., delivered the fourth and final lecture of his course on "Applications of Electric Heating."

On the motion of the Chairman, a vote of thanks was accorded to Professor Fleming for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

CONVERSAZIONE.

The Society's Conversazione will be held this year at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday, May 30th, from 9 p.m. to 12.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

SIXTEENTH ORDINARY MEETING.

Wednesday, March 29th, 1911; Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society :—

Browell, Colonel Edward Thomas (late R.A.), Merrow House, near Guildford, Surrey.

Cotman, Henry William, The Quadrant, St. Ives, Hunts, and the Arts Club, 40, Dover-street, W.

Evans, J. Howell, M.A., M.B., M.Ch. (Oxon.), F.R.C.S., 25, Berkeley-square, W.

Graham, W. L., 33, Bowerdean-street, Fulham, S.W., and Bon Accord Sheet Metal Works, Townmead-road, Fulham, S.W.

Hudson, Lieut.-Colonel Sir William Brereton, K.C.I.E., Fairholme, West Kensington, W.

Khan, Khur Shaid Ali, c/o Messrs. Henry Adams and Son, 60, Queen Victoria-street, E.C.

Provis, Charles Herbert, Highfield, Mutley-road, Plymouth.

The following candidates were balloted for and duly elected members of the Society :—

Eccles, Ernest Edward, M.I.E.E., Foyers, Lochness, Scotland.

Rahder, Christiaan Lydius, LL.D., Sourabaya, Java, Netherlands East Indies.

Ritchie, W. W., District Postmaster, Chengtu, West China.

Sang, Alfred, 96 Boulevard de Versailles, St. Cloud, Seine-et-Oise, France.

Stewart, Professor Louis Beaufort, University of Toronto, Toronto, Canada.

The CHAIRMAN said that in the Book of Nehemiah iii., 8, it was recorded that among those who volunteered to assist the Prophet in the restoration of the walls of Jerusalem were Uzziel of the Goldsmiths' Guild, and Hananiah of the Apothecaries' Association; and this fact, recalled to mind by him when receiving the invitation to take the chair there that evening, was the determining cause of his accepting it, quite unworthy as he felt he was to preside over a meeting of the Royal Society of Arts on so important an occasion. He had argued that as the goldsmiths' art and the

art of the apothecary were the oldest arts in the world, and among the earliest named in the oldest Sacred Books of the human race, there was after all, something of propriety, if only of a whimsical sort, in his sitting in the chair on the evening Mr. Heming stood at the reading-desk. But the predetermining cause of his so doing was his deep interest in the subject of Mr. Heming's paper, and his keen appreciation of Mr. Heming's work in artistic plate and jewelry; and furthermore of his patriotic and successful labours, so sympathetically and laudably recognised by the Goldsmiths' Company, in organising, within and by the trade itself, a system of sound and thorough-going education alike in the artistry and the technique of their deviceful and exquisite, and noble and famous, and most ancient art. The recognised successor of the late Robert Philips of Cockspur-street, as an exponent of the traditionary styles of English goldsmithing and jewelry, Mr. G. B. Heming needed no introduction to the members of the Royal Society of Arts, but in consideration of the subject of his paper, he (the Chairman) desired at once to emphasise how apt an illustration Mr. Heming was in himself of the immeasurable value of heredity in the maintenance of high excellencies in the practice of artistic industries, or the applied arts generally, and especially of the sumptuary arts.

To begin with, his very name bewrayed him a Dane, and of a family the Hundred Rolls showed to have already by the thirteenth century become established in Yorkshire, Lincolnshire, Norfolk, Cambridgeshire, Northamptonshire, Suffolk, and Essex. The Wars of the Roses broke up the continuity of family life throughout England; but some of these families recovered their position, and resumed their historical continuity in the Parish Registries, under the Tudors; from which date the name of Heming became familiar in London from Bethnal Green way and Highgate to Charing Cross.

Thomas Heming, Goldsmith to George II. and George III., was well known to every lover of English plate for his fine silverwork, bearing dates from 1745 to 1780; and from him his business has descended, from father to son, to the lecturer of that evening. This heredity was the secret of the Hindu's excellency in the industrial arts; and when you praised a Hindu goldsmith, or wood or stone carver, or weaver, or potter for his work, he would reply that he was but handing down the ever-accumulating merit of his forefathers—through nearly 3,000 years past—to his children, and children's children; and he prayed it might so accumulate through them for yet 3,000 years to come. Such facts should not be overlooked when considering the pressing problem of technical education in every department of industrial activity and enterprise throughout the United Kingdom. He had stood too long between Mr. Heming and his audience, and without further parley would now ask Mr. Heming kindly to proceed with his paper.

The paper read was—

ART EDUCATION IN THE JEWELRY, GOLDSMITHING, AND ALLIED TRADES.

By George B. Heming.

The statement has often been made, and is constantly repeated, that the English are an inartistic nation. If, for the sake of argument, we admit this rather sweeping assertion, it is obvious that the duty of protecting and encouraging good art is incumbent upon us all; but if we were the most artistically-minded people on the face of the earth, it would none the less be our duty to defend our art from the morbid tendencies, the careless design, the crude execution, the purposeless and unmeaning absurdities which can so easily undermine the beauty and mar the expression of works of art, whether they find their theme in music, in painting, sculpture, or architecture. In this paper, however, which it is my privilege to read before a Society that has consistently been on the side of good art, my remarks must be confined to art in its relation to those trades that have always prided themselves upon the production of beautiful objects.

Trades like those of the goldsmith and the silversmith demand, on the part of the persons engaged in them, a certain knowledge of drawing and modelling, in addition to dexterity in the manipulation of the materials in which they work. The introduction of machinery has increased the production of gold and silver articles, but it has naturally affected the position of the working goldsmiths and silversmiths, and in many cases their crafts have disappeared, or have become subdivided into many branches, and come at last to be considered as separate trades. In that fine old Anglo-Saxon word, "craft," meaning grasp, power, ability, particularly skill or cunning in artistry of hand, we touch the crucial point of our subject. With the advent of the machine we almost bid farewell to the craftsman—the man who fashioned a thing carefully and lovingly with his own hands from beginning to end, who put into it—who, indeed, could not help putting into it—something of his own personality, and who gave it a unity of adornment both simple and natural. "Fine art," said Ruskin, "must always be produced by the subtlest of all machines, which is the human hand; no machine yet contrived will ever equal the delicate machinery of the human fingers." "Time was," wrote William Morris, "when everyone that made anything

made a work of art besides a useful piece of goods, and it gave him pleasure to do it." Under the present conditions, each item is machined out in facsimile of its predecessor, and the pleasure of the workman only comes with the daily closing hour and his pay-day at the end of the week. How can such methods result in anything but the deterioration of artistic work of any kind, and the degradation of the artistic workman? In olden times, what was sought in any craft was that each article produced should possess two qualities—first, a design combining suitability to the purpose the article was intended to subserve with elegance of proportion; secondly, soundness of construction. From this standard the demon of the machine pulled us down, and things were probably at their worst about the middle of the nineteenth century, when all the decorative art of this country reached an unprecedented state of decadence and disrepute. It was Ruskin who first preached the gospel that our daily work should be more than a mere struggle for our daily bread. "Whatever you are to make your bread by," he wrote, "so far as you have time and power, make yourself first a noble and accomplished artist, and understand at least what noble and accomplished art is; you will then be able to apply your knowledge to any service." To us, living under an economic stress even greater than was the case when Ruskin wrote those words, such utterances may sound to some present as those of a voice crying in the wilderness; but I will venture to say that, despite the economic and social problems which we have to confront—the problem of producing quantity without a dead level of sameness, and often of unutterable ugliness—the antagonism between art and the machine is not irreconcilable, nor so hopeless as it appears, and that the day of the revival of the British craftsman is not far distant, and, indeed, is near at hand.

Bearing on this question, I will condense a few admirable remarks from an address delivered by Mr. Luther Hooper on Handicraft at Haslemere:—

"Handicraft is not the mere skill of hand acquired by constantly practising one particular movement or set of movements; in fact, the same uniform and uninteresting qualities which we deprecate in machine-work might be produced by hand, when by mechanical practice and repetition the hand had been degraded to the level of a machine. Work deserving the name of handicraft must be produced by the skilful hand under *the direct control of the thinking power of the worker*—under the direct control of his brain; and the excellence of his work would depend on the artistic power and judgment brought to bear upon it." He believed in the use of machines and labour-saving appliances, provided that the work done by their means could not be better done by hand; but we must see that the machine-made article is as good for utilitarian purpose as the hand-made one. "Up to a certain point the machine was a good, useful, and economical servant, but its perfection was a dead level of uniformity, unpleasing and dull, and its imitations of ornamental or other art were vulgar and pretentious failures—in short, it could not give that impress of thought and mind to its work which renders the simplest specimen of true handicraft more or less satisfactory and interesting. The advantage of handicraft was that it imparted a personal quality to all work produced, and it was that expression of the artist's self which made it interesting."

For the last twenty-five years we have been placidly watching the advance of our French and German competitors in all industrial and commercial matters, forgetful of its true significance and of the national interests at stake. Germany's stupendous economic success is largely due to her national system of specialised education, and her State support of scientific, learned, artistic, and economic activities in every part of the Empire. France also, progressing by fits and starts, but with a vivacity that compensates for the more stolid advance of the Teuton, is in many ways artistically far ahead of us, doubtless aided by the Latin temperament of her people. It behoves us to awake from our lethargy of self-complacence, and to move at least abreast with France and Germany. If our jewelry trade, and the trades dealing with the precious metals—of which, you will bear in mind, I am particularly speaking—are to be maintained against the inroads of foreign competition, and saved from obliteration, we must not lose a moment in our endeavour to improve the technical and artistic education of the young "apprentice" and "improver" in these trades, encouraging him by every means in our power, and, if necessary, founding travelling scholarships to enable him to broaden his knowledge and enlarge his ideas by visits to France, Italy, and Germany. As a people, we desire—or ought to desire—not only material prosperity; we look forward beyond that to a future of the highest artistic achievement; and I see no reason why the two ends we would set before us should be regarded as incompatible. The attainment of these ends should at least be particularly dear to us all. We undoubtedly possess many of the essentials of success in such a competition. Why, then, should our ambitions be low? A trade such

as ours—which, it must be remembered, offers exceptional opportunities for the expression of artistic values, and has attracted by its possibilities many eminent artist-designers and workers of exquisite ability and manipulative cunning, whose names are familiar to you—should be always boldly progressive and sagaciously self-confident in its attempt to raise its standard. That our neighbours across the Channel have realised this is one of the secrets of their splendid successes in jewelry and goldsmithing. A charge is often brought against us that we produce no great artists, but my belief is that we have as many artists in our trade as the French, but unappreciated, unregarded, and, therefore, undiscovered. I wish, however, not to deal in vague generalities; my idea is to treat this subject as far as possible from a practical point of view, with the endeavour to create the artist-craftsman, as contrasted with the idealist, whose art I fully appreciate, but who, for the present, at any rate, aims too high for this commercial age. For it must be borne in mind that we are faced with two considerations—one the demand for artistic ornament, the other the gratification of vanity; and in some instances, of course, the cost of the materials employed introduces a third. For years we have been content to import our designs; we have grown so accustomed to this free trade in art that we have overlooked our own native designers and the possibility of their higher education. Happily, there are not wanting indications of a much more hopeful state of things in the next few years, although we have a difficult task before us.

Before proceeding to describe what is being done here in London towards the solution of the difficulty, and to suggest what may yet be done for the education of the practical apprentice, I may, perhaps, with advantage outline some of the methods that are being pursued abroad for the training of the art student in jewelry, goldsmithing, and kindred work; and you will observe that not only is he trained, but he is encouraged in every imaginable way to excel. The School of Industrial Arts, Geneva, founded in 1876, administered by the city and the Swiss Government, will provide us with an object-lesson. The aim of this school is to qualify boys and girls for positions in all artistic crafts and trades; pupils are admitted at the age of fifteen, and are taken through a course extending over four or five years, according to the particular calling for which they are preparing. The school for teaching decorative art directs especial attention to theoretical work; the school of industrial art devotes itself exclusively to the practical side, but does not allow pupils to neglect those studies in design, modelling, and composition which are indispensable for the successful practical pursuit of any artistic craft. If an aptitude for the fine arts is shown, it is encouraged, and a pupil of talent will be assisted in his living expenses, so that he shall not be hindered on the road to success by extraneous worries. The students are practically apprentices, paying *no* premium, receiving *no* remuneration, and turning out excellent work under the direction of experts. All materials—such as marble, silver, gold—are supplied free; the articles produced become the property of the school, and their sale is a source of revenue. The conditions differ entirely from those which obtain in our English schools of art. There is no preponderance of immature learners acting as a drag on the class-work, no attendance merely to pass the time; the single endeavour is to teach and to learn some art-trade in the most perfect manner. Complete and saleable work is insisted upon in every department; nothing sketchy or unfinished is allowed to pass; every trained student can command his price in the market, and on leaving the school can immediately earn a fair salary.

This school cost the city of Geneva £40,000 for building and equipment, and the expense of maintenance is £5,000 per annum, half of which is provided by the State and half by the city; it is free to all, even to students from foreign countries. The principle of free education has long prevailed in Geneva, and has contributed largely to the industrial prosperity of the Swiss Republic. In order to qualify for entry, a pupil must have passed the primary schools. When he has selected a craft—enamelling, for example—he must study several subjects which will bear upon it from an artistic point of view. Thus, at the finish of his time, he is something more than an enameller; he is an artist, and is looked upon by employers as infinitely better than one who has been merely apprenticed in a workshop. Diplomas and certificates of capacity are given to students who pass the necessary tests.

Thus is Switzerland, one of the smallest of nations, holding its own through the turmoil in which art is at present involved, asserting its tastes, expressing its individuality, setting a great and salutary example to Europe, giving new life to art and a new tone to that life throughout the world. When the work of the individual

citizen is so important, each person so thoroughly trained helps in the general progression of the world, and adds his stone to the immortal monument of history.

In Paris, again, systematic training of the young, on sound methods, was adopted more than thirty years ago as a feature of the artistic trades. The goldsmiths and silversmiths there regarded education as an urgent personal matter, and started schools with a common view of raising the standard of work and the status of the workman; the latter, as a rule, naturally being a corollary of the former. They had a membership list of 700, divided into sections, for their different work. The members went to the classes to see that the boys studied in a right spirit. During a stay in Paris, in 1908, I visited some of the schools, and found fifty or sixty boys in each class, all of them earnest and keen to learn their business. They were taken at intervals, in small companies of three or four, to examine the works of art in the museums, under the supervision of the committee. Having witnessed how any sign of artistic ability is encouraged in the French boy, I cannot help comparing him with the type of English youngsters whom one frequently sees in our various museums, wandering aimlessly through the different galleries, taking no interest whatever in the beautiful objects that surround them. In the French provincial townships, also, schools of commerce and industry have been in existence since 1892, organised for the instruction of workmen who have to take their places in various departments of trade, and assisted by the State. The committees which advise the schools are almost exclusively composed of manufacturers and traders, and, as a consequence, the students are supervised by men who are exceptionally qualified to see that the instruction is of such a nature as to have a practical and beneficial bearing upon the particular industries of the locality. The French Society for the Encouragement of Goldsmiths' Work—gem-work and the designing of personal ornament—originated in 1865, when a Monsieur Baugrand offered a sum of 500 francs as an award to the apprentice who should be adjudged most meritorious both on account of work and conduct. In 1874 another patriotic Frenchman set apart sufficient capital to enable a certain sum to be devoted annually to the encouragement of the best qualities in the *personnel* of this branch of industry; the result was the formation of a permanent society with the title I have mentioned. An interesting side-light is thrown upon the secondary but very important question of how careful training may improve character and manners. "The members of our trade," said a former president of this Society of Goldsmiths, "should clearly understand that our interests lie in the good conduct of our workshops as much as in the perfection of the work which is sent out from them. For this reason we should encourage our workmen to set a good example to the young people under them; we should seek to develop in our apprentices, character, desire for professional knowledge, and general aptitude for their work. The pursuit of such aims will certainly be of benefit to us all." Two kinds of prizes are given—one for excellence of work, the other as a recognition of moral qualities. This may come as a surprise to those who share the popular idea of France as a decadent nation. Awards are instituted for artists and manufacturers who, by their creative genius, or by their distinction in the teaching of their work-people, have assisted the progress of the industry; competitions, with additional prizes, are held for designers; and since 1887 a medal has been offered annually to the Guild of Engravers for workers in all kinds of metals. In 1890 an annual travelling scholarship of the value of 400 francs was founded, with the object of assisting employees to improve their position by the study of foreign languages, and of affording skilled craftsmen an opportunity of investigating processes of manufacture in other countries. Details of many other competitions, arising naturally and easily from the main original scheme, I need not give here; enough to say that from such nurseries of art and industry it is no wonder if a breed of skilled workmen and conscientious artisans is arising which must of necessity add to the wealth and prosperity of the respective countries; nor is it a matter for surprise that at the present moment, in the higher branches of jewelry, the foreigner monopolises 60 per cent. of our workshops—is better both in design and execution than our own home people, and more often than not displaces the Englishman when especially clever and fine work is in view, and this, in spite of the fact that a good English workman is second to none—save on the artistic side—in practical work.

All this energy, all this admirably systematised teaching, all this careful "education" of the boy—the possible artist—in the work which he prefers, whatever it be, tends, you will perceive, to the rehabilitation of the craftsman; and the question is probably already

uppermost in your minds: What are we doing in England, in the face of so discriminating a treatment of the problem in countries which the average Briton is too prone to look upon with a genial contempt? What are we doing here—in England? It is certain that there were periods in which the English goldsmith and silversmith showed great originality and taste, and in the olden times he occasionally produced a really great work of art. London, in the twelfth and thirteenth centuries, had its many guilds, that of the goldsmiths among others; but the City guilds suffered a serious eclipse during many centuries as far as the fostering of fine achievement in their respective trades was concerned; and what I wish is that they would now take up a similar work to that accomplished by the trades and municipal bodies in France and Switzerland, which I have already mentioned, so that our British work in designing and creating objects of applied art should not lag behind that of other countries. This question was partly dealt with, with a note of hope, in the *Journal* of your Society for last September, in an unsigned article, from which I will quote a paragraph:—

"Some designers would tell us that there is no longer a living to be made out of design. Some manufacturers would say, with equal sincerity, that there is no employing a student who has been educated at a school of art; they find they must train their men themselves. Whatever the cause, there seems no doubt that at the present time comparatively little attention is being paid by the schools to design for manufacture. Until some years ago the artistic crafts had been neglected; now, they are not only considered, but they take the first place. It is a pity, not, indeed, that students should design for the crafts, but that a greater number of both teachers and taught do not realise how necessary it is that design for manufacture should be our first consideration. It is wrong to ignore the artistic possibilities of the more ordinary objects. It would surely be a higher aim to try to make manufacture artistic, as far as may be, than it is to turn one's back on it or stand aloof in proud superiority."

That last sentence embodies the scheme on which I wish to engage your attention during the remaining portion of my paper, and as briefly as possible I will set before you what has already been done in the matter as far as our own city is concerned.

It was considered desirable to invite the co-operation of the leading members of our trade with the workers, in order to obtain opinions and experiences relating to the problems we had to face, and almost exactly three years ago, on March 10th, 1908, a meeting of manufacturing goldsmiths, jewelers, and silversmiths was held at Goldsmiths' Hall. Its object was outlined in the notice which we issued, from which I quote:—"To discuss the system of technical education as now applied to our trades, and to consider a scheme for imparting the necessary knowledge of drawing and designing to our apprentices and improvers, in view of the ever-growing demand by the public for more artistic goods, and the Continental competition to supply the same. The necessary instruction, it is felt, can only be successful by making *compulsory* the attendance of youths in their masters' time, and by recognising this as part and parcel of their daily work." The proposal submitted by the conveners of this meeting was to the effect that the classes suggested should be held from 5 to 7 p.m., at the present City and West-End technical schools, once or twice a week, for drawing and designing in all its branches, under efficient masters, thus enabling the manufacturers in our trades to make compulsory the attendance of their respective "apprentices" and "improvers." My use of the word "compulsory" must not be misunderstood; by it I do not of course mean that boys and young men should be forced to do this work against their will, or that individual liberty should be interfered with, but that such training should be, as I have just said, a part and parcel of the daily duties. At this meeting a preliminary committee was formed, which delivered its report and expounded its suggestions at a second meeting held on May 28th following. It decided that a society should be constituted combining the whole of the allied trades, wholesale and retail, with the title of "The Goldsmiths', Silversmiths', and Jewellers' Art Council," its objects being, firstly, to advance the practical and historical knowledge of art and design, as applied to these industries; secondly, to promote and carry out any kindred object for the well-being and advancement of the trade in general. The suggested course of action was eminently practical; it included classes, confined entirely to members of the trade, to be held at the Northampton Institute and the Central School of Arts and Crafts on four days a week, Mondays, Tuesdays, Wednesdays, and Thursdays, from 5 to 7 p.m., so that youths could attend on whichever evening might be most convenient to their employers. At these classes instruction should be given in freehand drawing, geometry, modelling, drawing from the antique, the cast,

plants, and still life, with short lectures on the history and development of art; finally, designing and painting should enter into the curriculum, in addition to the ordinary course of technical education and practical work in the evening classes. The committee considered that the system of technical education up to that time prevailing was not a success; boys were expected to re-learn work that should have become familiar in their own workshops, and were also given work beyond their capabilities; the study of art and its history was non-existent. It was recommended that the executive committee to be elected should be allowed the privilege of assisting the authorities in the proper directing of these classes, and also in the selection of suitable teachers.

With that second meeting, the indifference that had fallen on our trade began to be shaken off; those who had never given the subject an hour's thought fell into line, and realised that the education of future generations depends upon the energy of the present—realised, too, that this scheme held remarkable possibilities, apart from mere accuracy and improvement of handiwork—that it would encourage a spirit of ambition in the younger members, and a determination to make their way in the world. From this meeting, at which Lord Henry Bentinck, Dr. Mullineux Walmsley, and many other gentlemen spoke in support of our scheme, we date the formation of our Art Council. On June 25th a deputation was received by the Education Committee of the London County Council, and discussed the various questions involved, such as, for instance, the augmentation of the already existent evening classes, the attendance of learners during business hours, the formation of an Advisory Committee to assist in the management of the schools, and more especially in the selection of teachers, and so forth. By the end of that year, 1908, we were in fair working order; "The Goldsmiths', Silversmiths', and Jewellers' Art Council" was beginning to be felt as an influence, and there was some prospect, if things went well, of ultimately displacing the slipshod methods which were a disgrace to any nation priding itself upon the slightest acquaintance with the meaning of the word "artistic," and of setting in their stead a thoroughly organised system of training, which in the course of time should bear a rich harvest.

Meanwhile, pending the conclusion of the negotiations, we were eager to make a start on the good work. It will be remembered that the year 1908 was the year of the Franco-British Exhibition, with its wonderful display of modern French jewelry and goldsmithing—a display which roused the deepest interest in the minds of all who saw it, whether they regarded it merely as an exhibition of beautiful work, arranged to give pleasure to the eye of the beholder, or as something more significant. The Worshipful Company of Goldsmiths generously placed at our disposal funds with which to purchase five hundred tickets of admission for craftsmen in the trade, and to contribute to the travelling expenses of the holders, in order that they might study the collections in the Palaces of Applied Art and other buildings similarly useful. In this connection, I offered prizes for essays, by workmen over and under twenty-one years of age, on "The Benefit of Art Education as Applied to the Goldsmiths', Silversmiths', and Jewellers' Industries, and as Exemplified by the Exhibit of Plate and Jewelry at the Franco-British Exhibition." A considerable number of excellent essays were sent in, and the prizes were distributed at Goldsmiths' Hall on December 8th. I may digress here for a moment to quote from the admirable address delivered by Mr. Henry Wilson, at the Royal College of Art, on that occasion. After referring to the time when the English goldsmith was famed throughout the Continent, and when his handiwork and services were sought for as are those of France to-day, Mr. Wilson proceeded:—

"The technical skill and artistry of the Anglo-Saxon jeweler were only equalled, hardly surpassed, by the finest works of the Greeks and Etruscans, while Celtic work, or the gold-work of Ireland, which some suppose to have been produced by British refugees, has never been surpassed. Where are they now? The best English jewelry is produced either in Paris or by foreign workmen in England, which is as much as to say that the Parisian gibe, 'There is no English jewelry,' is true. I was discussing the matter of English goldsmiths' design with a very great Continental artist, who said:—'You have the fox which isn't like a fox, the horse-shoe and the riding-whip and the hunting-cap, the knot and the bow of ribbon, and the crescent, and you don't seem to be able to think of anything else. Your wildest flight of fancy never goes beyond festoons, or wreaths, or a menagerie of diamond animals.' Of course I did not like this. I knew it was so true. Yet how are we to avoid it? How are we to emulate the artistic achievements of the Continent and regain our lost artistic eminence? There are some who say:—'By educating our young workmen in the same way as those of France and Germany are educated.' We are assured that if we adopt similar methods, we shall have similar results. I think not. All

the foreign methods in the world would never make an English boy anything but English. It is not the method which makes the man, but the man the method. French and German methods are right because they are the outcome and the development of the respective needs of those countries. What saves others will not save us, for no two individuals are exactly alike."

To avoid any possibility of misunderstanding, I may perhaps mention that it is no part of our programme to adopt slavishly Continental methods, or to impose designs of foreign origin, beautiful though they may be, upon the attention of the English pupils; to direct them, rather, to consider wherein beauty consists, and to encourage their individual expression of it, is our hope, and the aim from which we endeavour not to diverge. These classes, then, are at the present moment in working order; that they are needed is evident from the fact that, at the census of 1901, the number of persons stated to be following the occupation of goldsmith, silversmith, and jeweller in the County of London was 7,390, of whom 657 were employers. The course of instruction which *we* should like pursued in the classes I may here outline roughly. In the first year, simple designs of lines, plain surfaces, round objects; designs after embossed work and plaster casts; plain use of the brush in wash-drawing. Second year: geometrical designs, perspective, drawings of ornamental plants, and ideas taken from the styles of the Middle Ages and the Renaissance of the seventeenth and eighteenth centuries. Third year: compositions after the antique and modern styles; embossed work, modelling, compositions after Nature, and the conventional treatment of flowers. Fourth year: designs and compositions after various periods, and the gradual composition of ornamental designs suitable for the needs of the crafts. Fifth year: advanced modelling, studies from life, thorough studies of the different styles; visits to the museums, with discussions and studies of classic and modern goldsmiths' work. Each and all of these studies can be modified to suit particular students, and blackboard lessons, lectures on the principles of design and on historic design should be a part of the method for advanced students. The whole scheme, in fact, while keeping strictly to its primary aims, is not rigid; it is flexible enough to allow for individual tastes and peculiarities, for only by such judicious flexibility, I am convinced, can the finest results be obtained.

"Trade without trade education," said Mr. Henry Wilson, in his draft report on one of our new schools, "is one, if not the chief, cause of unemployment. . . . No trade is justified unless it lift the worker and widen his horizon, unless it educate him. . . . You cannot expect beauty in the workshop if there be none in the school. You cannot produce fine work with faulty tools, nor good workmen from damaged material. . . . The connection between manual skill and intellectual ability is invariable. This means that for the majority of mankind the workshop is the best of schools, and that the best school is that most resembling the workshop, and that each system is at its highest when it is the means of the completed culture of the greatest number. It is not the amount of knowledge, but the quality of culture which counts."

These concluding words, which I should like to impress upon all who have to do with the training of the young, bring to my mind an accessory subject which appeals to me very strongly—the pitiable lack of ordinary education in the vast majority of those who apply for positions in our shops or workshops to-day. The boy looks smart, perhaps, but he does not know enough of the rudiments of politeness to remove his cap when he enters the sanctum of his prospective employer. The man seems promising, but he cannot write a decent letter, and his spelling of simple words would move one to laughter, were it not so pathetic in its significance of his limited outlook and cramped brain. I have in my own experience encountered numbers of such boys and men, and doubtless every person in this audience who has had occasion to employ labour can reinforce my complaint. Last December the London County Council took a step that may lead to encouraging results in this respect; it decided to establish, as part of its elementary school system, a series of higher schools to be termed "Central Schools," which should aim to give their pupils a definite bias towards some kind of industrial or commercial career; these pupils will enter at about the age of eleven or twelve years. At that age the character is not fully or rigidly formed; the receptivity of the brain and mind is not yet declining, and there is some hope that the combination of an industrial tendency with the normal process of education may make for the inculcation of manners, of a proper respect for seniors, and of a behaviour which shall be decent and dignified and orderly without being stiff or smug, or merely "put on" for the occasion. In this, I maintain, our schools

are doing a beneficial work. Unless he conforms to the discipline required of him, the learner finds himself at a standstill; but, as a matter of fact, he generally does so conform, and there is no reason to suspect that he finds it irksome. He enters into a new world—the world of art; and, as art progresses, life should become more beautiful. Our schools, in addition to cultivating this taste for beauty, and diffusing sound knowledge of its rules, are turning out highly competent workmen who are now in the trade. We are working, as it were, with saplings, which we trust will gather strength from the roots we so recently planted, and we look forward to see the mature, giant oaks which shall give strength and unity to the steady progress of art in objects of both use and ornament. "Inform a pupil's mind," said Ruskin, "refine his habits, and you reform and refine his designs." The epigram might almost be reversed — refine his designs, cause him to look on beautiful things, and you refine his mind.

In concluding, I must touch briefly upon the question of the teacher and his methods. Drawing, of course, is the basis from which the edifice is to be reared; art training should begin with the first lesson in drawing. It is a fact that often the first efforts of young pupils are better than the first attempts of those who begin later; they are less self-conscious, less contaminated by the influences of surrounding ugliness. To postpone the development of this power of expression is to cause it to wither; but the utmost care is necessary in the teacher. In fact, we may say that the more elementary the student, the higher the skill required in those who are to direct the first faltering steps. The teacher should not make too much of his own individual ideas; he must remember that his duty is not to force the pupil into his own already formed mould, into his own fixed style of work, but to find out that pupil's possibilities, and to encourage any efforts after originality, however tentative they may at first glance seem. It is the expression of the artist's self in a work that gives it interest, and training must be directed toward that end. I believe, with Mr. Catterson-Smith, that while the advantages of teaching simple drawing are obvious, there is a grave danger in the present system of what is called "teaching design." His experience was that children commonly possess an inherent *gift* of designing in much finer form than the ability to design can be acquired by teaching, and he suggested that drawing from Nature should take the place of the copying of stereotyped designs, which tends to damp down any originality in design with which the learner may be naturally endowed. If instruction in drawing were organised in our elementary schools on a large scale and on a serious footing, every child could be judged as to his or her fitness for further artistic education previously to entering any trade wherein art dominates the output; in fact, such training would often be a most useful factor in determining the child's true vocation. This additional teaching of drawing is quite in harmony with modern tendencies. It supplements the equipment of the mind with some general notions of art—vague, perhaps, at first, but later on to be crystallised into definite and defensible principles; it encourages in due time—always presuming that we speak of an intelligent student — the study of the history of epochs and of styles; it enables him to gaze upon fine works of art, whether they be paintings or sculptures, jewels or engravings, chased silver or enamelled gold, with the seeing eye, enables him to thrill in response to the touch of the long-dead artist, to know what a man meant, and how he felt when he laboured for long, splendid hours to bring to birth a thing of beauty and enduring joy. "Encourage the student," wrote Ruskin, "in sketching accurately and continually from Nature anything that comes in his way. . . . You have often to obtain beauty and display invention without direct representation of Nature, yet the principle is perfectly simple. If the designer of cups and vases and the like exercises himself continually in the imitation of natural form, he may pass down into all kinds of geometrical or formal design with safety and noble results."

Too much emphasis, therefore, cannot be given to the importance of a judicious selection of teachers. Each trade ought to be completely and exhaustively looked after by experts in that particular branch of education. It ought to be, so to say, artistically self-supporting. The self-importance of the average present-day teacher is to a certain extent a hindrance to the student. If a teacher would begin by putting himself at the level of the pupil, endeavouring to ascertain what is in the pupil's mind, here and there making a suggestion which might seem of no use to a listener, but which by its tactfulness might inspire one still better from the pupil, and thus breed in him self-confidence and a harmless conceit, he would not only be aiding the young mind in its development, but recompensing himself; for he would perceive

a little of the magnificence of the fresh, untrammelled brain grasping eagerly at what is essential to it. As a consultative committee of the trade, we are endeavouring to evolve the type of teacher required.

You will have it in mind to say, perhaps, in reply to my enthusiasm with regard to the introduction of artistic methods and designs into the articles of use and ornament which it is the especial province of the goldsmiths' and silversmiths' trades to produce, that all this is of little practical value unless the public will show some artistic predilections as well—that, putting it baldly, we cannot make pretty things simply to be looked at. I am happy to be able to anticipate any such hypothetical comments by stating that, along with the return of the craftsman, there are plentiful signs that the public is showing a remarkable revived interest in articles of beauty. "Art in England has never been dead," said Mr. A. Gilbert, R.A., "but only hibernating; its revival has come about chiefly through the great educational advance in the country, and the possibilities of study that have come with it." It is indeed time that something happened. What are we to think of the state of the goldsmith's art, formerly so dignified, so pure, so securely set on its pinnacle of fame throughout Europe, when imitations and the cheapest of gilt, worthless things degrade it every day in all our shop windows? How is the fine craft of the silversmith fallen when we descend to the kitchen and scullery for designs; when drapers, stationers, and chemists sell by the hundred-thousand trumpery articles and gewgaws of every description, stamped out of silver thinner than paper—silver that you can dent easily with the pressure of a finger-nail! Again, how great an anomaly is it to value a man's work by its weight in ounces, disregarding its loveliness, its evidence of careful, sensitive craft-labour! Truly, a few years ago it seemed as though the art of the worker in precious metals had sunk beyond redemption. Fortunately, as I observed, there is now a rapidly increasing proportion of the public, educated in matters artistic, capable of appreciating really good work, and insistent upon getting it, and willing to pay a fair price for it. My fear is that the scheme of educating the workmen will only partially succeed unless the men through whom the creations are to reach the larger public are equally tutored in art—I mean the retailers, who alone come into close touch with the purchasers. Even this difficulty will, I believe, be gradually surmounted, since any scheme which affects the manufacturing section of the trade must react upon the retailers.

Finally, permit me to affirm that this enterprise on behalf of which I speak, the interests of which I have so nearly at heart, is of a kind which, if wisely directed, will mark an epoch in the annals of commerce and of my own trade in particular, and will mark, too, a notable advanced stage in the evolution of the British applied arts especially. What final form the scheme will take cannot as yet be foreseen, but it is impossible to mistake the significance of the work, and of the persistence with which it is being carried on. By scholarships, and by annual professional competitions in design and artistic work of all kinds, we seek to encourage the development of a true taste for the beautiful; and I wish especially to emphasise the fact, already referred to at some length, that art is a most potent refining influence on the whole life of men and nations. We must follow out our mission—for such we feel it to be—perseveringly, undeterred by temporary checks or fleeting failures; we must mark the way, set high examples, remind ourselves that a country is great because of the greatness of its individuals, its industries, and its commerce; and that a nation is artistic because its individual men and women have listened to the divine call of beauty, and have attempted to pass on to the world its haunting, unforgettable tones.

In our way, we have made a beginning. It may seem small at times, but great progress has already been made, and it may turn out to be the lever to move the overwhelming weight of dullness and apathy that has rested upon an ancient and artistic craft for now nearly three generations. If those present, many of whom have enriched art, will now discuss the question freely, it will be a powerful encouragement to the movement.

Permit me to thank you, as a Society, most warmly for allowing me to read this paper upon a problem, the solution of which must interest every true lover of art—a problem which, when solved, will bring back the halcyon days William Morris must have borne in mind when he wrote: "Art is the expression of the workman's joy in his labour."

DISCUSSION.

The CHAIRMAN, in opening the discussion, said the favour with which his audience had received every paragraph of Mr. Heming's lecture, and the applause with which at the close they had emphasised their approval of it, made it really

superfluous for him to say more than how heartily he had shared their pleasure in it, and with what clearness and strength of conviction he sympathised with the views and opinions expressed by Mr. Heming on the past history, the present position, and the hopeful future of technical education in the artistic crafts of the United Kingdom. It was indeed a great privilege for us all, and a great encouragement for those of us who might be occupied as the business of our lives in these manufactures—using that word in its original sense as the antithesis of "machinations"—to have heard from so distinguished a practical authority as Mr. G. B. Heming, and out of his own mouth, how unhesitating was his confidence in the British workman, in every department of craftsmanship, if he were but adequately educated for his handiwork, and properly paid for it—an honest living wage; and how successful he had been in initiating something like a revival of the old system of apprenticeship for the education of workmen in his (Mr. Heming's) own trade of jewelry and goldsmithing; and to have been enabled, furthermore, to judge for themselves, from all they had heard there that evening, that Mr. Heming's prognostications of the prosperity awaiting our British industrial arts or artistic industries were as well founded and sagacious as they were enthusiastic and inspiriting.

He was particularly pleased in having found Mr. Heming so strongly insisting that students of art, devoting themselves to the practice of the industrial arts, should have previously had some experience of the trade in which they proposed to earn their livelihood; that is, of the character and working up of the materials, stone, clay, wood, wool, cotton, linen, silk, copper, brass, silver, gold, and gems, etc., used in the manufacture of sumptuary goods for household and personal use and ornament. In this way only should we ever get British art-workers of the type of the perfected hereditary handicraftsmen of the Indian democratic trades-union villages and caste guilds; the real makers, and the maintainers, through every economic and political catastrophe, however revolutionary, of the true greatness of India—India of the Hindus. The description given of the craftsmen of Anterior Asia in Ecclesiasticus xxxviii. exactly applied to them, and was, moreover, so profitable for our own instruction, correction, reproof, and stimulation, that he would quote it at some length. After saying how the ploughman gloried in his goad, and set his heart upon turning a straight furrow, and was wakeful to give his heifers their fodder, it continued:—"So is every artificer . . . . They that cut gravings of signets. And his diligence is to make great variety. He will set his heart to preserve a good likeness in his portraiture; and will be wakeful to finish his work betimes. So is the smith by the anvil . . . . He will set his heart upon perfecting his work . . . . and his eyes are upon the pattern of the vessel . . . . and he will be wakeful to adorn them perfectly. So is the potter . . . . and all his handiwork is by number . . . . And he will be wakeful to make clean his furnace. All these put their trust in their hands, and each becometh wise in his own work. Without these shall not a city be inhabited. And men shall not sojourn nor walk up and down therein . . . . But they will maintain the fabric of the world (or 'age'). AND IN THE HANDIWORK OF THEIR CRAFT IS THEIR PRAYER." This was a photographic picture of the landscape, life, and labour of the Indian Hindu villages, and of the all-pervading and sustaining, and all-comforting and sanctifying religious spirit that animated them; and their joy in their gods was their strength. We might have our Territorials, "all the King's soldiers, and all the King's men," and all were needed, to their full "establishment," but the "Trained-bands" required for the enduring conservation and defence of the United Kingdom, were our technically and artistically trained British workmen; and in their making or marring was directly involved the making or the marring of the entire British Empire.

But what he most sympathised with in Mr. Heming's paper was the depth and steadfastness and devoutness of the feeling that emphasised it throughout—as it ever had all his work, whether as a jeweler and goldsmith, or as an educational reformer on behalf of his trade. In this respect he recalled to his mind the saintly John Hungerford Pollen, of whom he (the Chairman), when occupying the chair at his paper on "Renaissance Woodwork in England" (on January 5th, 1898), said:—"Mr. John Hungerford Pollen always reminds me of Theophilus the Monk, who in his book on the 'Industrial Arts' recommends the study of them as a recompense of heavenly price; and asks those who found pleasure and profit in his books to pray for the pity on him of Almighty God, Who knew that he had written the things (recipes, etc.) to be found therein, not for the praise of men, but for the greater glory of Him in whose divine counsels and genius every artist was a participator." The latter thought was expressed in the Book of Wisdom ix. 8-10. Again we read in Exodus xxxi. 2-6 of the master craftsmen, Bezaleel and Aholiab:—"And I have filled them with the Spirit of God, in wisdom, and in understanding, and in knowledge, to devise cunning works in gold, and in silver, and in brass, and in cutting of silver for setting, and in carving of wood in all manner of workmanship."

Both art and religion had each its own special content; but the truth was that all art which rested on earnest and efficacious feeling inevitably became inspired by, and in turn inspired, religious emotion, and reached its highest heights of achievement only in the deliberate expression and exposition of religious feeling—and if "the beauty of holiness" and the holiness of beauty were not absolutely one, they were at least inseparable from each other—twin streams flowing from the same fountain-head, and to the one self-same infinite and mystic sea of tranced immortalities.

Mr. S. LOWEN (Secretary of the Goldsmiths' Trades Union) paid a high tribute to the labours of the author during the last few years in bringing about a betterment in the industry. He thought, however, that Mr. Heming took a rather pessimistic view of the ignorance of the British workman and the number of foreigners in British workshops; indeed, he believed there were not more than 30 per cent. of foreigners in the diamond and gold industry at the present moment. With regard to the question of artistic work, there was a tendency of many employers nowadays, when a workman had put all his soul into an article, to dismiss him for being too long over it. Only the previous evening he had had a case before him of an enthusiastic workman—quite an artist—who was really a versatile man in his ability, but who was dismissed for being too long completing his work. The employer was, perhaps, not so much to blame as the shopkeeper. Mr. Heming had referred to the question of educating the workman, but in his (the speaker's) opinion it was the shopkeeper who needed education, from the artistic point of view. The average salesman had no eye to taste, and could not point to any of the beauties of a particular article which he might be selling, and all the credit which he (the speaker) could give that individual was the credit for not trying so to do! With reference to designs, the system in London did not obtain in Paris. The Masters' Association in Paris were not cutters of prices. He instanced a case where an employer informed him some time ago that he had left a very high-class design, which involved considerable labour, with a West-End firm. Manufacturers called and gave different estimates, with the result that the lowest estimate obtained the work. Now, that was neither fair to the workman, to the industry, nor to the public. Mr. Heming's efforts, however, during the last few years had given such a fillip to education that the trade would never again retrograde. The Franco-British Exhibition gave great encouragement to everybody in the industry, and he thought the author took heart when he saw the splendidly improved work there. He suggested to the Committee of the Art Council, with reference to their competitions, that too much attention should not be paid to the amount of work a man could do in a given time. That, he was of opinion, was a great drawback to the competition, and he hoped for an alteration in that respect in the future.

Mr. JOHN WILLIAMS thanked the author for his paper, especially for the very hopeful tone he had taken throughout with regard to the trades and the education connected with them. The account Mr. Heming gave of the schools in Geneva and Paris was most valuable, but it must be remembered that in comparing the work of those schools with the schools in this country, the school in Geneva had been in operation for thirty-five years, and the French school for forty-six years. It was only within the last few years this country had possessed such an institution as the Goldsmiths', Silversmiths', and Jewellers' Art Council, and therefore it was at least thirty years behind both Switzerland and France. There were two points which, in his opinion, stood out above any others in Mr. Heming's paper. The first was as to the necessity for compulsory education of apprentices and learners. It seemed that in the schools mentioned in the paper, compulsory attendance was always the rule. That applied also to most of the German schools. Secondly, there was the absolute necessity for the employers and workers to take a greater share in the future in the matter of art education amongst the younger members of the trade. On both those points he maintained that England was not on the same level as the Continental schools. In England, up till the last year or so, the voluntary attendance of boys and young men at evening classes—after they had left work—was not to be depended upon. Anyone who had experience of the matter would know that the attendance was affected by extra pressure of work before Christmas, the slackness after that time, and bad weather. It certainly was asking a great deal of a boy who had been in a shop all day to attend evening classes. But, in spite of those obstacles, many boys attended, and really did good work. Those difficulties, however, did not apply to the classes which had been established by the Goldsmiths' and Silversmiths' Art Council, as the boys were allowed to attend to their lessons in their employers' time, and therefore much more regular attendance and systematic work resulted. Even under the classes as they existed at present, however, the attendance did not allow of efficient teaching in many of the subjects. Mr. Heming spoke of classes of fifty or sixty in Paris schools. Even with the help of the Goldsmiths' and Silversmiths' Art Council, classes of that kind could not be arranged in this country. What was obtained was one class of boys in their first year, and another class in their fifth or sixth year, and classes composed of boys who came from different kinds of shops. On the other hand, the Continental schools, by having a larger number of pupils in their classes, could better organise the work, and give the subjects greater division and attention. The author had given a very good account of the grade of teacher that he wished evolved. He (the speaker) did not think that "evolved" was really the right word. He was sure that there were already in existence teachers who were not only sympathetic, but anxious to do the best they could for the students—men and women who came to them for advice and assistance; and if the Goldsmiths' and Silversmiths' Art Council would encourage them, they would rise to far greater heights than they had in the past. The co-operation of the Council and educationalists, he felt sure, would result in a system of education which would in time equal that of the Continental schools.

Dr. W. Garnett (Educational Adviser to the London County Council) said he was no artist and no craftsman, and was not qualified to address the audience on any subject bearing upon art, but he would be greatly helped in his work if some gentleman could give him some suggestions, firstly, on the extent to which machinery and the study of machinery should be introduced into schools of arts and crafts in connection with the training of the designer, and, secondly, on the extent to which such machinery, if at all, should be introduced in connection with the training of the craftsman. By machinery he did not mean simply machine-tools, which were mere adjuncts to handwork, but machinery of more or less automatic character. He had recently seen a manifesto from an Association of Art Masters, in which it was said that the schools had not been enabled sufficiently to come into touch with manufacturers in connection with the design and production of machine-made artistic goods, and they urged that some steps should be taken in that direction. Communications in the public press, and elsewhere, had also appeared, urging the same point, namely, that the machine had come to stay, and that unless the artist was to be dominated by the machine, he must become its master, and that it was important the schools should become thoroughly conversant with machine production in order that their designs might be adapted thereto. Hitherto he had been unable to get any but simple suggestions with regard to the particular kinds of machinery that should be introduced. For instance, he had been told that a hand-loom was most important in connection with the design of textiles, and that spinning machinery for metals was equally important in craft schools in which metal work was being carried out; but beyond those two comparatively simple suggestions he had been unable to learn what sort of machinery was required. He was strongly convinced that the designer should know all that was to be known respecting the limitations of his design which were necessary for its adaptation to the machinery by which it was to be produced, but that did not necessarily mean that the machinery itself was to be introduced into the schools. It seemed to him that, at any rate in the training of the designer, what was most wanted was that such co-operation between the manufacturer and the schools should be obtained as would enable the young students to be taken in small groups over the works to see the machinery actually producing, and to learn as much about it as was necessary to guide them in connection with their designs. He had generally recognised the principle that in the training of the craftsman, whether in engineering, building, or art, the main essential was to produce a good hand-worker, and that afterwards he would quickly learn the use of labour-saving machinery when he got the opportunity.

Mr. Alan S. Cole, C.B., agreed entirely with the reader of the paper in what he had done and was doing in connecting together trade and educational interests. It was most important that such a connection should exist. Although the author had not referred to them—perhaps intentionally—there were in Birmingham and Sheffield just as fine schools of art in their way as any on the Continent. With regard to the training of people in art crafts, and the application of design to particular materials of all sorts, as far as the schools of art in this country were concerned, the Government by its grants and regulations—some of which, however, were very harassing—had for the last fifteen years encouraged them as far as possible to take up the direct instruction of design in connection with various materials, but the outcome of the movement was not appreciated by the public. If any one went, say to South Kensington, and saw one of the National Competitions, he would find some extraordinarily fine work, but the public did not care one jot or tittle about it. The Government was a great deal to blame in the matter; it gave most meagre accommodation to the exhibition, and as time went on the exhibition would probably be set aside altogether. He thought it was a crying shame that the Government, who professed to encourage design and art in all its forms, should extinguish practically that most important annual exhibition, of which the public could know hardly anything at all.

Mr. J. S. Bell said he desired to refer to the question of patronage. Those connected with the trades mentioned in the paper had made great efforts to produce the highest class of workmanship possible, and any who visited the West-End shops would be surprised if they were, so to speak, to get behind the counter, to see the art treasures there collected. There were some magnificent collections in the British Museum and elsewhere, but he could assure the audience that the same could be found at any of the West-End establishments. The author had referred to the Art Council, but such a scheme was nothing new; there had been art schools and art training during all his experience of the trade, which extended over thirty-five years. What he did deplore was the change of ideas. The aristocracy of this country were so enamoured of their motor-cars and such like, that they gave no thought to art. The idea at the present time seemed to be that anything in art must be old and antique, and then it was looked upon as a sort of idol, but to anyone who knew anything about the manufacture of such articles it was a mere whim or fancy. Such things, he maintained, could be produced at the present time if only the public would give the necessary encouragement and appreciate high-class work. If they did give that encouragement it would give a great incentive towards art training.

Mr. Henry Wilson said he felt the subject raised by Dr. Garnett was of great interest, but great

reflection was necessary before one could give utterance to any opinions that were likely to be of value. The first thing he would do would be to repeat the remark made by Dr. Garnett, that the man must dominate the machine, because that was only common-sense. He would quote for example the die. The die, by which the most perfect piece of work of art the world had ever seen —the Greek medallion—was created, was nothing more nor less than a machine. There was no reason why works of art of a very noble and beautiful character could not be repeated *ad infinitum*, because everything depended, not upon the machine, not upon the use of the machine, but upon the design of the machine; that was to say, it was the man behind the machine who always had to be considered. It did not matter from whatever point of view the question of art was regarded, it was not the tool or the machine or the education or the training—it was the man. Therefore, with regard to the points raised by Dr. Garnett, he felt there was so much to be said that a conference of educationalists and artists and workmen of all kinds should be held in order that the matter might be thoroughly thrashed out. In his opinion, there was not at the present time any education of any kind, artistic or otherwise, which was properly organised; the whole system of education was in a haphazard state, and for no earthly reason. There was splendid raw material at hand, and why should not the best be made of that raw material? He fully believed, and he had had some considerable experience, that there was nothing in the world to equal the young English boy, who had an almost divine appreciation of beauty, and a sensitiveness to form and line which would not be found in any other part of the world. It certainly would not be found in France, where there was an amazing and wonderful intellectuality, but that which made the English boy's charm was not present; it was steel put against fine gold. That fact, however, did not blind him to the extraordinary defects in this country's scheme of education. With regard to the question of spinning, he could not help feeling that there was a great future for the use of spinning in the production of simple, beautiful things for everyday use. He did not think spinning ought to be used in what one might call monumental works; for instance, cups of any sort, or chalices, the whole of which work ought to be done, from the base to the summit, absolutely by hand; but for things of everyday use he did not see why there should not be a group of artists, who might be called spinning artists, who would evolve out of their experience a whole series of beautiful and lovely contours, such as could be seen on a Greek vase. The Greek artist was a consummate contour artist because he had a consummate knowledge of the human figure. He would like to suggest that there should be some attempt made by the trade to develop spinning works of contour. He could not sit down without publicly thanking Sir George Birdwood for that wonderful book of his "The Industrial Arts of India." He (the speaker) owed more to that book than to any other that had been written on the subject of art, and he never looked at it without feeling his gratitude welling up from within him. He used to wonder how Sir George had written such a book, but he was quite certain now that he had not written it—the Spirit of India had taken hold of Sir George Birdwood and had inspired him.

A vote of thanks was accorded to the author for his interesting paper.

Mr. Heming, in reply, said he felt more than gratified by the reception of his paper, and also by the large company present, representing as they did a great section of the silversmiths, jewelers, and goldsmiths of London. He could only hope that the remarks he had made would strike home, and that the Art Council, which was now in its third year, would be supported to a larger extent. He trusted that the Goldsmiths' Company, which was supposed to represent the trade, would come to the rescue and not only morally but financially support the Council. He was pleased to hear from Mr. Lowen that he was wrong about the percentage of foreigners in the trade. With regard to Dr. Garnett's remarks about machinery, he (the author) was absolutely opposed to its introduction. If once it was introduced, hand-workmanship would never be reverted to. The whole object of his Society had been to raise the standard of work by doing away with machines, and to produce work such as the old masters in the earlier centuries did. He wanted the public to appreciate such work, and if they did, it could be produced.

ARTS AND CRAFTS.

Some Pottery for the Turin Exhibition.—It was allowed on all sides that the pottery exhibits from this country were amongst the most interesting features of last year's Brussels Exhibition. It was not merely that a good number of manufacturers showed, but that their wares were marked by a great advance in a number of directions. There has, therefore, been a strong feeling that we must at all costs send a fine collection of pottery to Turin to follow up the good impression that has been created. A distinct portion of the British building at the forthcoming exhibition has been set aside for ceramics, and a number of the principal firms are contributing towards what will be, it is hoped, an epoch-making exhibition of British pottery. The largest exhibit will be that of the Pilkington Tile and Pottery Company, who have taken a double space, and intend to show a large octagonal case full of painted lustre, from which will radiate eight ordinary exhibition cases, one or two of which will be given up to lustre, whilst others will illustrate a variety of different glazes and methods, arranged according to colour.

The vases to be exhibited at Turin were shown at Clifton Junction for three days before they were sent off, and they formed a remarkably fine collection. It was, of course, in the painted lustre for the centre case that the interest of the little exhibition culminated. Mr. William Burton, the managing director of the company, and his brother, Mr. Joseph Burton, have been working for some years to produce new effects on old lines—not by haphazard methods, but by the most careful following out of scientific principles. The results of their labours, so far as they have gone, have been shown at previous exhibitions, but the examples going to Turin mark a very great step forward. In the first place, their range of colours has been materially increased. They have been producing painted lustre work on a variety of coloured backgrounds for some time past, and the available grounds now include, besides more ordinary colours, a very rich deep blue, as well as a tint closely resembling a powder blue and a kind of powder green. Some very beautiful effects are obtained by so scheming the colours that the background tint is often deeper, and sometimes quite different on the lower part of the vase. People who know the difficulties incident to the firing of lustre, and of special pottery glazes, will appreciate the mastery over the means of production which the power to do this kind of thing at will involves. The newest and most striking colour-scheme is given by a small group of vases in which the prevailing tint is a kind of peach blow, which varies from green through a delicate pinkish shade, to a beautiful fiery sunset colour. The highest point to which pictorial representation can go without overstepping the mark is well illustrated in a large vase, very simple and severe in form, on which is painted a procession of sailing ships. The green and orange, and the endless gradations of colour between the two, succeed in producing a peculiarly tender colour arrangement suggestive of something between sunset and moonlight—and one feels that all the essentials of artistic effect are there without any sacrifice of the reticence and the breadth which the material demands.

A few of the bowls are slightly modelled both inside and out by hand, and by this means they gain a certain personal quality at the same time as they afford a more varied surface for the display of the lustre. The slightly raised slip patterns which occur on a few of the pots also help to display the beauties both of the lustre and of the glaze to full advantage. The designs with which the vases are decorated vary from flatly treated figure and animal forms to ornament pure and simple. Some of them are sufficiently modern in character to belong completely to the twentieth century, whilst others, and by no means the least successful of them, are reminiscent of old work. This is specially the case with some of the ornamental allover patterns, where the colour-scheme of the painting recalls instinctively old Oriental ceramics. It is by no means the least of the makers' achievements that they have succeeded in producing something which, while it recalls the various lustre wares of the past, sometimes in colour, sometimes in treatment, sometimes in design, is distinctly and distinctively of our own time. One feels that, had there been no Persian, no Hispano-moresque, no Italian lustre ware, these vases would never have seen the light, but while the makers have learnt all they can from the old master potters, their work is pre-eminently their own. It is only reasonable, when one comes to think about it, that as men of old time have had their share in the evolution of the modern man, so the art of the past should play its part in helping to produce the art of to-day. It is to his grasp of this fact, not usually appreciated at the present time, almost as much as to his scientific knowledge and ability, that Mr. Burton's remarkable success is due. Some of the plain lustre pots are beautiful in colour, and the smoke-like effects in particular are wonderfully pleasing. The remaining exhibits consist largely of crystalline and other transmutation glazes, and of eggshell, fruit skin, and other glazes which give a matt surface. The fiery crystalline glaze is peculiarly fine, whilst the more subtle colour produced by the break of some of the more delicate coloured glazes is hardly less beautiful. The most interesting of the matt glazes are the blues and greens. The old bright blue has now given place to a full blue with a greenish tinge which brings it more towards a peacock, and the effect of this on a large pot, where one part looks bluish and another greenish, is very attractive. Again, some of the greens slightly speckled with brown have a very delightful quality. A show like this should produce a great deal of comment at Turin, and will certainly more than hold its own against all competitors.

Slovak Embroidery.—We have been rather overdone of recent years in England with exhibitions of the peasant art of various countries and peoples, but the little show of Slovak art at the Doré Gallery is well worth a visit. The pottery, though characteristic enough, is rough ware covered with tin enamel, which calls for little comment, but the embroidery is really remarkable. The handiwork of a Slav people settled in Central Europe, it offers, both in technique and in design, an interesting example of work which, though neither wholly Eastern nor Western, has a good many characteristics both of the East and of the West, and it merits study by all those who are interested in the connection between Eastern and Western art, or who think they know something about the design and workmanship of the embroidery of the Near East. There is a certain amount of Slovak embroidery scattered about the museums of central Europe, but as it is generally labelled Hungarian (since the majority of the Slovaks live in Hungary) it is generally taken to be the work of Magyars, and probably few of those who were interested in the show of needlework at the Hungarian Exhibition at Earl's

Court some years ago realised how much of the best embroidery was Slovak. At Bond-street some of the most interesting work might almost pass for Persian from its method and its colouring, whilst other pieces are quite unmistakably European. One form of needlework which the Slovaks have carried to great perfection is a sort of pierced work (such as used in early Victorian days to be called Madeira work) executed usually in yellow on white, or in blue on black, with sometimes the addition of further ornament in gold and silver thread. Most of the silk embroidery is characterised by its vivid colouring which, for all its brightness seems never, at least in the older work, to strike a false note. The gold work is remarkable partly because a good deal of it is stitched in fine gold thread which is carried through the material, instead of being couched upon it, and partly for the characteristic patterns worked over stiff cardboard. The chasuble embroidered by a Slovak peasant woman from her own (evidently traditional) design, is a very interesting example of how well good peasant work can be adapted to ecclesiastical uses — but one could wish that the figure-panel in the centre had been omitted; it is out of harmony with its surroundings, and not the best type of figure embroidery.

HOME INDUSTRIES.

The Coal Mines Bill.—It was said here last week that it was to be regretted that the second reading of this Bill was not preceded by the usual full discussion. It is a Bill of great complexity, dealing with matters of great moment to a large section of the industrial community, and whilst on the whole the measure appears to commend itself to those most concerned, and best able to judge of its merits and defects, some serious criticism has to be answered. The mining danger which attracts the greatest amount of public attention is explosions, and here it is alleged the Bill is defective, is indeed said to be distinctly retrograde. The section in the Bill dealing with the use of safety-lamps says:—"No light or lamp other than a locked safety-lamp shall be allowed or used (*a*) in any seam where the air current in the main return airway is found normally to contain more than half per cent. of inflammable gas." Sub-sections of this section provide for the use of safety-lamps in parts of a mine, but do not affect the general question. Now it is said, among others by Mr. George H. Winstanley, who speaks with authority, that such a determining factor as that named—more than half per cent. of inflammable gas in the main return airway — would exempt from the general use of safety-lamps a large number of collieries where safety-lamps are, and for years have been, used. The best ventilation is generally to be found in the mines which are the most dangerous as regards the freedom with which fire-damp is given off, and these are the mines in which, as a result of that good ventilation, there is rarely "more than half per cent. of inflammable gas" in the main return airway. To quote Mr. Winstanley:—"There are many collieries in Lancashire in which the ventilating volume amounts to from ten thousand to twenty-five thousand tons of air per twenty-four hours. On the other hand, in those mines which claim to be free, or relatively free, from fire-damp, the ventilation is often poor, and whilst it would be quite easy to keep below the determining limit in the main return airway, there may be dangerous proportions of gas in other parts of the mine." That section of the Bill dealing with the compulsory adoption of safety-lamps seems to be in need of stiffening, and doubtless this will be emphasised in the discussions at the conferences between the owners and the men, and in Grand Committee.

Anglo-Egyptian Trade.—There is a good deal in what Mr. Thomas Roberts, a British commercial agent in Egypt, says about the possibility of expansion of British trade with Egypt, if only British merchants and manufacturers would pay more attention to native requirements by getting more in touch with the natives. The principal means by which the British trading position in Egypt can be improved seem to be three: (1) That English commercial travellers should be able to speak French; (2) that catalogues should be printed in French as well as English; (3) that there should be an exhibition of British industries supported by the Board of Trade. An effort is now being made to arrange for such an exhibition to be held in Cairo. Whether it will be successful depends upon the willingness, or otherwise, of the British Government to give it the necessary support. Mr. Roberts, who speaks from a long experience of Egyptian requirements, says there is a preference for the following articles of English make:—Cheap crockery, sanitary ware, boots, underclothing, cloths, ready-made suits, linoleum, furniture, clocks, carpets, silvered glass, fishing tackle, guns, jewellery (cheap), confectionery, flour, pickles, biscuits, soaps, paints, oils, whiskies, pitch, paper, rope, hats, buttons, pins, fencing, tinplates, lace curtains, salt fish, matches, bedsteads, bicycles, motor-cars, saddlery, pianos, gramophones, threads, travelling bags, sporting requisites, worsteds, lead piping, cast-iron pipes, railway, tram, and ambulance fittings, etc. Generally these articles are required in cheap qualities.

The Boot and Shoe Trade.—Before the present United States tariff came into effect the annual exports of boots and shoes from the Leicester district to the United States were quite nominal, but for last year they amounted in value to £17,000. The American Consul for the district reports that they are invoiced as "high-class walking boots and shoes." Shipments of these goods have been made to Cincinnati, Boston (two firms), New York (five different firms), Philadelphia (two firms), San Francisco, Pittsburg, Columbus, Ohio (four firms), Chicago, Cleveland, Kansas City

(six firms), and Portland, Oregon. A good proportion of the boots and shoes exported to the United States and Canada are shipped at the Manchester Docks, the goods being forwarded by rail direct from the manufacturing centres to alongside the steamers, thus reducing the cost of transit and handling of the goods to a minimum. Through railway rates are quoted from Nottingham, Leicester, Kettering, Northampton, and other manufacturing centres, not only to the Manchester Docks, but also through to the Western States. The saving in delivering from the works to f.o.b. Manchester, compared with Liverpool, varies from 2*s.* 6*d.* to about 4*s.* per ton.

Short Time in the Cotton Industry.—As was anticipated in these Notes, the percentage of spinners required to bring about short time, that is to say, 90 per cent., has not been obtained. Many members of the Federation believed the proposal to be inopportune. The *Cotton Factory Times* admits that "the immediate necessity for going on short time is hardly as pressing as it has been on some other occasions," but thinks that "a compulsory Saturday stoppage all round would bring about regularity of employment on the remaining days." If that were so there would be much to be said for the stoppage, but would it be so? The number of spindles would probably increase if high profits were made. In 1903 and 1904 there was short time. In 1903 it lasted fourteen weeks, and affected both American and Egyptian cotton; in 1904 the American mills were on short time for thirty-six weeks, and the Egyptian mills for four weeks. This was quickly followed by an unexampled increase of spindles, which supports the conclusion that there was a connection between the expansion and the large amount of short time that preceded it. As it was then so it might be again.

NOTES ON BOOKS.

DICTIONARY OF ENGLISH AND SPANISH TECHNICAL AND COMMERCIAL TERMS. By William Jackson. London: E. & F. N. Spon. 2*s.* 6*d.* net.

This little book has been designed as a dictionary in two parts—English-Spanish and Spanish-English—of technical and commercial terms used principally in the iron, steel, hardware, and engineering trades. As the author remarks, the rapid development in these branches has brought into use many technical words and terms which are not given in the ordinary dictionaries, and are very hard to find. It is, of course, extremely difficult to draw up an exhaustive list of expressions used in any trade, and in a book of this sort one must look for a few omissions, but these appear to be somewhat numerous. A casual glance, *e.g.*, fails to find the words "braze," "brazier," "mud-guard," and "span"; but in spite of this the book supplies a very decided want, and should prove useful to many engaged in the trades concerned.

MEETINGS OF THE SOCIETY.

ORDINARY MEETING.

Wednesday evening, at 8 o'clock:—

APRIL 5.—HENRY L. HEATHCOTE, B.Sc., "Wheels, Ancient and Modern, and their Manufacture." The Hon. RICHARD CLERE PARSONS, M.A., Vice-President of the Society, will preside.

Dates to be hereafter announced:—

FRANK M. ANDREWS, "Architecture in America."

Professor RAOUL PICTET, "Les Basses Températures."

Sir WILLIAM ABNEY, K.C.B., D.C.L., D.Sc., F.R.S., "The Quantitative Measurement of Colour-Blindness."

HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

NOEL HEATON, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

A. W. GATTIE, "London Transport."

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

APRIL 27.—Sir THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord AVEBURY, D.C.L., LL.D., F.R.S., will preside.

MAY 25.—W. R. H. MERK, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

APRIL 4.—Captain R. MUIRHEAD COLLINS, R.N., C.M.G., Official Secretary in Great Britain for the Commonwealth of Australia, "The Commonwealth of Australia." The Right Hon. Lord DENMAN, K.C.V.O., Governor-General Designate of Australia, will preside.

MAY 9.—F. WILLIAMS TAYLOR, "Canada and Canadian Banking."

CANTOR LECTURES.

Monday Evenings, at 8 o'clock:—

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 3...Victoria Institute, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Rev. Canon Girdlestone, "Indications of a Scheme in the Universe."

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Professor J. H. Priestley, "Electricity as a Factor in Crop Production."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Mr. W. R. Baldwin-Wiseman, "The Administrative Aspect of Water Conservancy."

Chemical Industry (London Section), Burlington House, W., 8 p.m. Mr. C. Heycock, "Measurement of High Temperatures."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. D. Dinwiddy, "Annual Licence Values."

Engineers, Cleveland Institute of, Corporation-road, Middlesbrough, 7.30 p.m.

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Professor Selwyn Image, "Architecture in Paintings."

TUESDAY, APRIL 4...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Captain R. Muirhead Collins, "The Commonwealth of Australia."

Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Dr. D. S. Margoliouth, "The Universal Races Congress."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. M. Aurel Stein, "Explorations of Ancient Desert Sites in Central Asia." (Lecture III.)

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Mr. J. W. Smith, "The Improvement of Highways to Meet Modern Conditions of Traffic"; 2. Mr. H. P. Maybury, "Recent Development in Road Traffic, Road-Construction and Maintenance."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. S. Gardner, "A Visit to Some Irish Antiquities."

Zoological, Regent's-park, N.W., 8.30 p.m. 1. Dr. R. T. Leiper, "Demonstration of Nematode Parasites obtained from Animals in the Gardens." 2. Mr. F. E. Beddard, "Contributions to the Anatomy and Systematic Arrangement of the Cestoidea.—I. On some Mammalian Tapeworms." 3. Mr. J. A. Morch, "On the Natural History of Whalebone Whales."

WEDNESDAY, APRIL 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Henry L. Heathcote, "Wheels, Ancient and Modern, and their Manufacture."

Geological, Burlington House, W., 8 p.m.

Public Analysts, Chemical Society's Rooms, Burlington House, W., 8 p.m. 1. Messrs. G. E. Scott-Smith and John Evans, "The Analytical and Microscopical Examination of Compound Liquorice Powder." 2. Messrs. Raymond Ross and Joseph Race, (*a*) "Note on Almond and Apricot Kernel Oils"; (*b*) "Constants of Chicken and Turkey Fats." 3. Mr. John Golding, (*a*) "Note on Gerber's 'Sensal' Milk Test"; (*b*) "Note on Abnormal Cotton Cakes." 4. Messrs. J. H. Coste and L. Myddelton Nash, "A Further Contribution to the Question of Turpentine Substitutes."

United Service Institution, Whitehall, S.W., 3 p.m. Mr. A. Colquhoun, "The Strategical Problems in the Pacific."

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Exhibition of the Embalmed Head of Oliver Cromwell, with a Short Description and History of the Object.

Naval Architects, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C. Annual Conference, 11.30 a.m. 1. Address by the Chairman. 2. Professor J. J. Welch, "The Problem of Size in Battleships." 3. The Hon. C. A. Parsons and Mr. R. J. Walker, "Twelve Months' Experience with Geared Turbines in the Cargo Steamer 'Vespasian.'" 4. Mr. G. S. Baker, "The National Experimental Tank and its Equipment."

THURSDAY, APRIL 6...Naval Architects, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 11.30 a.m. 1. Mr. J. T. Milton, "Diesel Engines for Sea-Going Vessels." 2. Mr. F. H. Alexander, "The Influence of Longitudinal Distribution of Weight on the Bending Moments of Ships among Waves." 3. Mr. J. Montgomerie, "Considerations Affecting Local Strength Calculations of Ships."—7.30 p.m. 1. Dr. R. E. Froude, "The Acceleration in Front of a Propeller." 2. Engineer-Lieutenant A. Turner, "An Investigation into the Stresses in a Screw Propeller Blade."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Miss S. M. Baker, "On the Brown Seaweeds of the Salt Marsh." 2. Papers on "The Genus *Salicornia*," by Dr. C. E. Moss (History, Synonymy, and Phylogeny), Mr. E. J. Salisbury (Characters of the Species), and Dr. Ethel de Fraine (Anatomy).

Child Study, 90, Buckingham Palace-road, S.W., 7.30 p.m. Dr. A. R. Abelson, "The Measurement of the Intelligence: with special reference to Mentally Defective Children."

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. F. Tutin and H. W. B. Clewer, "The Constituents of Rhubarb." 2. Messrs. A. W. Crossley and C. H. Hampshire, "6-nitro-3:4:3':4'-tetramethyldiphenyl." 3. Messrs. J. J. Dobbie, J. J. Fox, and A. J. H. Gange, "Diphenylene, a new Aromatic Hydrocarbon. Part I." 4. Messrs. T. P. Hilditch and A. E. Dunstan, "The Correlation of Viscosity with other Physical Properties. Part I. —The Ethenoid and Ethinoid Unsaturation." 5. Mr. E. P. Perman, "Chemical Action induced by Cathode Rays and Canal Rays."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. A. Bone, "Surface Combustion and its Industrial Applications." (Lecture II.)

Architects, Society of, 28, Bedford-square, W.C., 8 p.m. Mr. Percy Macquoid, "English Furniture."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. J. E. Taylor, "Wireless Telegraphy Working in Relation to Interferences and Perturbations."

Philatelic, 4, Southampton-row, W.C., 6 p.m. Display of Portuguese Reprints, presented by H.M. the King of Portugal.

Roentgen Society, 19, Hanover-square, W., 8.15 p.m.

Concrete Institute, Denison House, Vauxhall Bridge-road, S.W., 8 p.m. Mr. C. P. Taylor, "The Reinforced-Concrete Pier at Swanscombe."

FRIDAY, APRIL 7...Naval Architects, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 11.30 a.m. 1. Dr. H. Frahm, "Results of Trials of the Anti-Rolling Tanks at Sea." 2. Dr. H. S. Hele-Shaw and Mr. F. Leigh Martineau, "Steering-Gear Experiments on the Turbine Yacht 'Albion.'" 3. Mr. S. B. Ralston, "Description of a Stability and Trim Calculator." 4. Mr. C. E. Inglis, "General Propositions and Diagrams relating to the Balancing of the Four-Cylinder Marine Engine."—7.30 p.m. 1. Professor E. G. Coker, "The Determination, by Photo-elastic Methods, of the Distribution of Stress in Ships' Plating." 2. Mr. M. Ballard, "Some Notes on a New Design of Merchant Vessel."

Civil Engineers, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. E. E. Farrant, "Retaining Walls."

Royal Institution, Albemarle-street, W., 9 p.m. Professor Sir J. J. Thomson, "A New Method of Chemical Analysis."

Geologists' Association, University College, W.C., 8 p.m. 1. Illustrated lecture on "The Scenery of Gloucestershire." 2. Mr. L. Richardson, "On the Sections of Forest Marble and Great Oolite on the Midland and South-Western Junction Railway between Cirencester and Chedworth, Gloucestershire."

Medical Officers of Health, 1, Upper Montague-street, W.C., 5 p.m. Dr. F. Foord Caiger, "Cubicle Isolation."

British Foundrymen's Association (London Branch), Cannon-street Hotel, E.C., 8 p.m. Mr. P. Longmuir, "Brasses and Bronzes."

Malacological, Burlington House, W., 8 p.m. 1. Mr. G. A. Smith, "A List of Marine Shells occurring at Christmas Island, Indian Ocean, with Description of New Species." 2. Lieut.-Colonel H. H. Godwin-Austin, "Description of *Oxytes Beddomei*, n. sp. from Burma." 3. Major A. J. Peile, "Note on the Habits of *Eurychlamys platychlamys*."

SATURDAY, APRIL 8...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Radiant Energy and Matter." (Lecture VI.)

Journal of the Royal Society of Arts.

No. 3,046. VOL. LIX.

FRIDAY, APRIL 7, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

CONVERSAZIONE.

The Society's Conversazione will be held this year at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday, May 30th, from 9 p.m. to 12.

PROCEEDINGS OF THE SOCIETY.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 5th, 1911; The Hon. RICHARD CLERE PARSONS, M.A., M.Inst.C.E., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society :—

Cope, Thomas, 27, Rosenthal-road, Catford, S.E.

Das, J. N., F.R.G.S., M.R.A.S., Khalispur H. E. School, Khulna, Bengal, India.

Gibson, Captain R. R., Immigration Office, Essequibo, British Guiana.

Giveen, Richard Lockwood, Colet-court, Hammersmith-road, W.

The following candidates were balloted for and duly elected members of the Society :—

Curtis, Professor Mattoon Monroe, A.M., Ph.D., 2045, Adelbert Road, Cleveland, Ohio, U.S.A.

Farrington, Henry, M.Sc., B.Eng., Popular Mechanics Company, Chicago, Illinois, U.S.A.

Howarth, Joseph, Kirkdale, Oldfield Lane, Dunham Massey, near Altrincham, Cheshire.

Samaddar, Professor Jogindra Nath, B.A., The College, Hazaribagh, Bengal, India.

The CHAIRMAN remarked that very few words were necessary from him in introducing the reader of the paper, Mr. Henry Heathcote, who was well known to many members as having devoted much attention to perfecting wire wheels. As everyone, every day of their lives, made use of wheels, all were very intimately interested in the question of their perfection. He anticipated a paper of very great interest to all.

The paper read was—

WHEELS, ANCIENT AND MODERN, AND THEIR MANUFACTURE.

By HENRY L. HEATHCOTE, B.Sc.

SCOPE OF THE PAPER.

The object of this paper is to present an account of some of the most ancient and most modern wheels, to describe their form, the materials used in their construction, and, as far as possible, the methods employed in their manufacture.

To prevent the account becoming too sketchy, it will be limited almost exclusively to vehicle wheels, and no attempt will be made to follow the application of wheels in the many arts which employ them.

The important advances which were made by the ancients when they began to employ wheels and rotating members in their mechanical contrivances, and the manifold latter-day developments and arts in which they are indispensable, form a chapter so vast that I have not attempted even the briefest summary.

Wheels for facilitating transit are therefore my theme, and no apology need be proffered for an account of what was one of the primitive inventions of mankind, and is of prominent importance to this day. There is a humanitarian as well as a scientific interest in this study of wheels. Throughout the ages, the use of wheels has played a crucial and ever-active part in the development of the means of intercommunication, now become so rapid and frequent as to form the ineradicable and predominating feature of our time. We know now how closely rapid intercommunication and civilisation are bound up together. Bearing this in mind, one need feel no compunction in drawing inferences as to the degree of civilisation of the ancient peoples from their wheels. The ancient Egyptians employed wheel vehicles for many purposes, and particularly for war, but the Israelites they held in

bondage had no chariots at that time. This stood them in good stead when crossing the Red Sea; the Israelites crossed safely on foot, but, according to Holy Writ, the wheels of the Egyptian chariots became (taking the marginal reading) bound so "that they drave heavily." This, which happened about 1490 B.C., is the earliest record I have found of wheel trouble, but for which the Israelites might never have reached the Promised Land.

Origin and Evolution of the Wheel.

The actual origin and inventor of the wheel are lost in the mists of antiquity. The use of it appears to have originated in the East and spread westwards. Doubtless the nomadic tribes would be among the first to discover the advantages of wheels. This may account for their widespread use at a very early date. The oldest Indian literature mentions wheels, showing their use as parts of vehicles as far back as 1700 B.C. This is about the date of the first reference to wheels in Holy Writ.

Those who seem most competent to judge, agree that the wheel took its origin from the cylindrical tree-trunks which were placed as rollers under a load. Probably the first vehicle was the sledge, the rollers being used when heavy masses had to be drawn. Rollers being in demand, and heavy ones being difficult to handle, it is likely that long ones were cut up to make small ones. The desirability of fixing these would soon become felt. Precisely how this was done we do not know, but conjecture suggests that the middle may have been grooved out to permit of a staple or pegs on the sledge engaging with the groove and preventing it running along or sideways. This groove may have come to extend the whole width of the sledge. A natural sequence would be to build this form up out of three parts —two disc-wheels and one axle, the axle being prevented by pegs from rolling away underneath the cart. Solid wheels were used by the less civilised nations of Asia Minor, and on the farm-carts of classic times. Virgil refers to solid wheels built up of three planks held together by an iron hoop, and this form is said to be still in use in Southern Italy and to make a loud creaking noise as it turns. Some of the old Chinese pictures show solid wheels with holes cut out, possibly for lightness, but more probably to admit a pole for skidding the wheel on a decline. This is an ancient method of braking, from which has arisen the phrase, "to put one's spoke into another man's wheel."

As late as thirty years ago bullock-carts were in use in Lisbon with only two such pegs to keep the axle in position. The body of the cart could be lifted right off the wheels, and even now solid wheels and axle are hewn in one piece out of tree-trunks and used for carts in the northern provinces of India. Solid wheels with iron axles are also used.

Splitting must have been a serious cause of trouble in ancient disc-wheels. Some that are still extant, dating from 1550 B.C., show bad splits and leathern thongs binding the parts together. Segments of tree-trunks would necessarily have a limited diameter, and though the large ones would prove better runners on rough roads they would be more likely to split. This may have led to planks being nailed together, some crosswise, and the survival of the fittest would account for their persistence. From this to radial planks cut parallel to the grain is not a long step, and from radial planks to spokes is a natural sequence.

The Wheel and Religion.

In India the wheel entered largely into the native rites of worship. Some of the religious writings contain an account of a mystic wheel, with a nave and tyre and a thousand spokes. The connection between the wheel and religion has been investigated by W. Simpson. The wheel was symbolic of the apparent rotation of the sun and stars, the worship of which led to the use of praying-wheels, circumambulation, processions, and other "circular" rites.

At this time, to speak of a man as being "like a wheel" was as complimentary as it now is uncomplimentary to call anyone a *roué*. It is interesting to note, in passing, that this degeneration probably arises out of the connection between vice and the use of the wheel as an instrument of torture.

It appears that India was not the only place where the wheel was held in veneration. M. Gadioz has discovered that there was a deity whose most prominent symbol was the wheel. Most of the figures of this god of the wheel are found upon French soil. The oldest represent Saturn holding up an eight-spoked wheel in the left hand; many show a six-spoked wheel. These date back to Teutonic times. Later the Gaulish Wheel-God became Romanised, and the figures take the form of a Roman holding a ten-spoked wheel. Altars have been found with an eight-spoked wheel carved on them. The Gauls of antiquity wore small wheels as amulets, some of which are to be seen in the British Museum, and are of bronze and about the size of a penny.

Other wheel amulets were of gold, silver, lead, and even terra-cotta. From the number that have been found in rivers and at fords it has been inferred that they were offerings to pacify the River-God and procure a safe crossing. Most of these have four spokes and a heavy rim.

The form of punishment known as breaking on the wheel is a survival of sacrificing to the Sun-God or Wheel-God, just as hanging is a survival of sacrificing to the Wind-God, and the nstitution of this horrible custom in France is doubtless connected with their greater familiarity with the Wheel-God. In 1534 this was the treatment reserved for highway robbers:—The condemned was first placed on a sort of St. Andrew's Cross with his limbs hanging between the four pieces of wood. The executioner then broke his arms, fore-arms, thighs, legs, and chest. The victim was then attached to the rim of a small coach-wheel suspended in the air by a thick post, the broken arms and legs were tied together behind his back and the wheel rotated.

Chariot Wheels.

We will now consider some of the early wheels a little more closely. The use of these for chariots led to a very advanced development even at a very early date.

The invention of chariots is ascribed by some to Erichthonius, son of Hephaestus and King of Athens, who flourished about 1460 B.C.; by others to the priest Trochilus or his son, Triptolemus. Homer described Telemachus as travelling from Pylos to Sparta in a chariot provided for him by Nestor:—

> The rage of thirst and hunger now suppress'd,
> The monarch turns him to his royal guest;
> And for the promis'd journey bids prepare,
> The smooth-haired horses, and the rapid car.

Probably, however, chariots had long before this been in use among the Egyptians. In Holy Writ we find two references to Egyptian chariots in use about 1715–1705 B.C. Chariots were, with very few exceptions, two-wheeled vehicles.

Design of Early Wheels.

Egyptian Wheels.—The Egyptian chariots, as shown by their sculptures, were easily carried by one man, and were, therefore, quite light. It is worth noticing, too, that the wheels were placed as far back as possible. In this position part of the load is borne by the horses. Since the chariot was so light this design could scarcely have been chosen to save them; the object must have been to lessen the load on the wheels and to reduce the shock transmitted to the rider.

The first slide shows a wheel found in the tomb of the Egyptian Tuiyu (1583 B.C.), now in the Cairo Museum. Round the rim is placed a leather tyre, so that the mighty dead should be protected against the shocks of the road when travelling during his second time on earth.

The Egyptian war chariots generally have six spokes, a few have eight, and others twelve; their private cars had only four. The spokes were usually round. The felloes were strengthened at the joints with bronze or brass bands, and the rim was a metal hoop. An Egyptian wheel has been found having a wooden tyre in six butt-ended segments, and a felloe in six segments lapped at their ends. The rim segments have four slots near the felloe, and bands of raw hide are passed through these slots to bind the rim and felloe segments together. The spokes are round and tapering near the nave, and square and tapering near the rim. They are provided with dowels at each end and a slot near the nave end, probably for a metal band. The diameter of this wheel is 3 feet 1 inch. In Egyptian wheels the axle-trees do not rotate, and the wheels are kept on by small linch-pins.

One of the Egyptian paintings in the British Museum shows a wheel with a nave in one piece and sockets for the six round spokes. At the end of each spoke is a T-piece, which forms a socket both for the spokes and for the segments of the tyre. There is also an Egyptian wheel in the British Museum. This is of wood, disc-shaped, flat on both sides and probably off a cart or truck used about 1550 B.C. It is still in excellent preservation and is about 2 feet in diameter, about 7 inches thick, with a cylindrical hole at the centre about 7 inches in diameter. It appears to have been cut from a solid tree-trunk.

Assyrian Wheels.—The Assyrian sculptures show three forms of wheel:—(1) Four-spoked, with heavy rims and tyres for heavy carriages. Some of the hand-carts shown in the sculptures have four very broad spokes, which look like boards. (2) Eight-spoked, with three concentric rings in the rim, the outermost being the tyre proper, and spokes fitting into sockets at the nave. These were for chariots. (3) Wheels with nail tyres. This slide shows the chariot of an Assyrian king, Assurbanipal (date 668–626 B.C.). Judging from the height of the horses and size of the men, these wheels must be from 5 to 6 feet in diameter. Note the tapering spokes, heavy-studded tyre, and four gaiters to keep the tyre on the rim. Occasionally we come across Assyrian wheels with twelve spokes. This slide shows a warrior's chariot with captives

in front. The wheel is not more than 3 feet 6 inches to 4 feet in diameter.

The next slide shows the hunting chariot of the Assyrian king, Assurnasirpal. These wheels are much smaller than the last, probably not more than 2 feet in diameter. You will note how very massive the tyre parts are in these wheels. The six spokes are comparatively slender. This suggests that they were either made of metal or that they presented their edges towards the outside. The tyres are generally built up of four, five, or six segments, the joints being sometimes at the spokes and sometimes between.

Persian Wheels.—The Persian relievos also show an advanced development. This slide shows a wheel with twelve ornamental spokes fitting into a rim carrying a studded tyre. These studs were doubtless intended to keep the metal tyre on the wooden felloe, but their number suggests strongly that, even in those very early times, they appreciated the need for some non-skid device.

Among the discoveries in South Germany are some iron tyres, all that remains of the chariot buried with some dead warrior. These tyres are about 40 inches in diameter, and are covered with radial spikes on the inside. On the outside are still left the overlapping scale-like heads of nails, just like the Assyrian and Persian tyres we have seen on the screen.

Cyrus, King of Persia about 560 B.C., made several improvements in chariots and chariot-wheels. We are told that he noticed how easily the wheels broke and built them stronger. He lengthened the axle to give chariots more rigidity, and at each axle end of the war-chariots he fixed a horizontal scythe, and underneath the chariot other scythes with their points turned towards earth.

Grecian Wheels.—The Greeks preferred wheels with four spokes. Some Greek vases (800–500 B.C.) show racing-chariots with wheels having four flat spokes. This slide is from a terra-cotta relief, and shows Paris abducting Helen. You will note how very crude this wheel is compared with the approximately contemporaneous Assyrian and Persian examples. The flat side of some Grecian spokes is wider at the nave than at the rim and parallel to the axle. Strengthening pieces appear always to be used at the junction of the rim and spokes, and the tyres are in segments—generally four or more—of flexible wood kept in place by an outer iron tyre. This slide shows a racing-chariot with eight spokes. Like the former, this Grecian wheel is quite small, probably not more than 20 inches in diameter. The slide shows the reins tied round the body of the charioteer, which, as you may remember, was their custom. The metæ are the conical posts which marked the turning-point; the spina is the low wall (or spine) running down the middle of the racecourse and round which the competitors had to drive. One vase (about 700 B.C.) shows a racing-chariot with two spokes, and two bars at right angles to these from one side of the rim to the other, but not passing through the nave. These wheels were made to rotate on the axle. The nave had an external ring of iron into which the spokes fitted, and a flat ring supported by a linch-pin prevented the wheel from coming off. Their diameter was for the most part under 30 inches, and the two wheels were nearly 7 feet apart.

Materials Used in Ancient Wheels.

The early Egyptian carriage-wheels were made of wood, and some of these are still in existence. Their sculptures show their methods of bending the felloes and rims, spoke-making and wheel-building. The spokes were shaved to make them round and smooth. The Egyptians knew how to produce iron as far back as 3733 B.C., but it was among the Assyrians that this metal was most freely used for the production of tools, weapons, and ornaments, and the Egyptians probably learned many of the uses of iron from them. We have already seen how the Assyrians applied their skill in metal-working to wheel-making, and doubtless their progress in this direction is closely connected with their military success.

According to Holy Writ, the wheels of Solomon's laver carriages (about 1000 B.C.) were bronze. We read :—"Their axle-trees and their naves and their felloes and their spokes were all molten." At the time of Judah (about 1440 B.C.) we read of the dwellers in the valleys of Palestine having chariots of iron. This probably refers to forged iron; cast-iron was probably not known till after the time of Homer (about 900 B.C.). The first Grecian wheels were made of oak. This slide shows the wheel of a funeral-car, which appears to be made entirely of wood, except for the tyre. The later Grecian wheels were made entirely of bronze. The next slide shows a bronze two-horse chariot. Homer speaks with enthusiasm of copper tyres (Iliad 5, 722 *et seq.*) :—

> Quickly Hebe fixed on the chariot the rounded wheels of copper, eight spoked, around an iron axle; their felloes were indeed of gold, imperishable, but around tyres of copper were firmly fitted, a wonder to behold.

Whether this was a detachable spare wheel that the Goddess of Youth was fitting to the chariot we are not told, but it is interesting to note how gold felloes pale into insignificance beside copper tyres that did not easily come off.

There are some antique bronze chariot-wheels still in existence at Toulouse. These are 54 centimetres in diameter, and have naves 40 centimetres long and 7 centimetres in diameter. The spokes are five in number, and there are deep recesses in the felloes to take the tyres. The rivets used for fastening on the wooden tyres can still be seen in the felloes.

Of early British wheels I have no examples to show. Cæsar, you may remember, found our ancestors possessed of war-chariots which they managed with great skill, implying a long previous acquaintance with the use and manufacture of wheels.

Ancient Wheels—General Considerations.

Before leaving these ancient wheels it is, perhaps, worth pausing a moment to consider their main features from one or two present-day points of view—*e.g.*, strength, serviceability, and appearance. In those times torque would only be applied to a wheel in its plane when occasion arose to put the shoulder to the wheel. They were not built to transmit torque, so when the Egyptian wheels sank in the sand of the Red Sea they gave trouble. The same must have happened in many other cases. Every time a car or chariot curved to the right or left a thrust on the rim would be developed perpendicular to the plane of the wheel, its magnitude depending on the weight, speed, and flexibility of the car, the radius of the curve and the character of the ground. The tendency of this would be to break the spokes near the nave. In overcoming this there are two paths open to the designer, one is to dish the wheel, the other to strengthen the rim—the former is the modern way, the latter was the method adopted by the ancients. The Greeks, as we have already noticed, provided strength to resist side-thrusts by sometimes employing spokes wider near the nave and with their flat side parallel to the axle. This was also the method employed for building one of the London Omnibus Company's wheels which came under my notice a few years ago.

With regard to serviceability, it is probable that these ancient wheels would work loose where the spokes enter the felloe and nave. This would lead to loud creaking and groaning, and probably partly explains why we read of the mother of Sisera listening for the noise of his chariot-wheels and not for the sound of his horses' hoofs. No doubt the sockets employed in the more recent of the ancient wheels served to strengthen the joints and minimise the noise.

With regard to appearance, even in very early times they preferred wheels with more spokes (eight and twelve) for war and state purposes. Where the wealth of Solomon made it possible, bronze wheels were preferred, and among the æsthetic Greeks the all-bronze wheel found considerable favour.

The foregoing account, incomplete though it is, will be sufficient to show that there was considerable variation in the design and materials employed by the ancients in wheel-making. Even the wheels of the same country differed considerably among themselves. As early as 500 B.C., wheels had reached a very advanced stage of development even in Europe, due partly to their use in war, partly to the sports of the Stadium, and partly to the rough roads and tracks they had to traverse.

Modern Wheels.

The Suspension Wheel.—We will now pass on to the next stage in wheel development, which dates from the use of bicycles. During this gap of about 2,500 years the only changes of any importance were the dishing of wheels to resist lateral stresses due to ruts and rounding corners, and arranging the spokes on two cones instead of one. This last was done as early as 1828, and is still used at Woolwich Arsenal in building ambulance-waggon wheels. Strange though it may appear, wheels were not used generally for facilitating transit in Britain till comparatively recent times. The very first carriage was made for Queen Elizabeth in 1568; the first that plied for hire in London were in 1625, and the first stage-coaches were in 1659. Broadly speaking, all the early wheels were compression wheels with radial spokes. The introduction of the suspension wheel for bicycles marked a great advance in the shock-absorbing powers of wheels. The first bicycle wheels were compression wheels, and had wooden spokes and rim with an iron tyre. The wheels were just ordinary light carriage wheels. The curved member connecting the back axle to the top of the front wheel is not altogether unlike that used in the chariots we have been looking at. Later bicycle wheels had radial-wire spokes which, being in tension, kept the rim in position. In the older wheels the rim was normally in tension, and the spokes and hub in compression. In a suspension wheel the spokes

and hub are in extension, while the rim is in compression. It is a common, though not unnatural error to suppose that the spokes of a modern bicycle wheel are sometimes in compression. As a matter of fact, they are always in tension, even those between the hub and the ground, when a heavy rider is in the saddle.

A suspension wheel has very little in common with a suspension bridge. If a number of contiguous canal bridges were built in a circle right round the earth, and the earth cored out, the resulting structure would much resemble a large wooden wheel, in which the compression due to the shrunk-on rim was replaced by that due to gravity. A like series of suspension bridges would, however, be quite unlike a wire wheel. In the latter there are no members whatever in compression between the rim and the hub, and its structure is more nearly related to that of a trellis which can be prevented from falling in in one direction by compression at right angles.

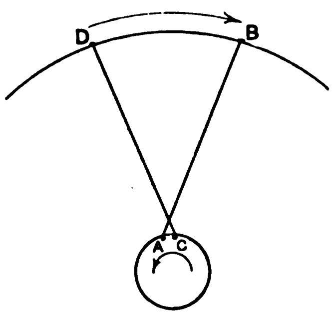

FIG. 1.

Fig. 1 represents one element of a wire wheel. If tension be applied to the spokes, the rim and hub would move towards one another were it not for the effect of the other segments; the resistance to the compression forces in the rim, and to the bursting stress in the hub shell prevents this movement. When compression is applied between the bottom of the rim and the hub-centre of such a wheel, the tension of each spoke will, if the rim is inflexible, decrease proportionately to the cosine of the angle between the spoke, or, rather, the projection of the spoke in the plane of the wheel, and the direction of compression. When the cosine becomes negative, as when the spoke is above its horizontal position, the decrease becomes, of course, an increase, having its maximum for spokes on the upper part of the wheel pointing in the direction of the compression. Obviously the spoke tension should never fall to zero nor rise above the elastic limit, and these limits help to regulate the choice of the initial spoke tension.

The Tangent-Spoke Wheel.—The tangent-spoke wheel, in which the spokes are tangent to a circle having its centre at the axle and are not normal to the rim, probably owes its origin to the curved arms used in driving pulleys and fly-wheels for transmitting considerable torque. This slide shows a bicycle of the transition stage—most of its spokes are radial—or nearly so; the rest are tangent to a circle of large diameter. The next slide shows an early tangent-spoke bicycle wheel, in which all the spokes are tangent to the same circle. Both ancient and modern *radial* spoke wheels are capable of transmitting a certain amount of torque, but the amount is limited, and depends not only on the bending strength of the spoke, but on the rigidity of its attachment to both rim and hub. Since no material has an infinite elasticity, it follows that however thick the spokes may be there must be a certain amount of twist of the hub (in the plane of the wheel) relatively to the rim, or no drive can be transmitted. When the torque is considerable—as in a motor-car rear wheel—the actual twist sooner or later rises above that corresponding to the elastic limit at some or all of the spoke attachments, and this leads to gradual loss of rigidity and to creaking, and, in some cases, even to charring owing to rubbing. In a radial-spoke bicycle wheel subjected to a torque in its plane, the hub must rotate relatively to the rim until the spokes are tangent to a small circle. If the average tension on the N spokes is t, when transmitting the torque T the tangent circle will have a radius—

$$r = \frac{T}{Nt} \text{ approx.}$$

Applying this to a bicycle wheel with fifty spokes, and assuming the pull in the chain to be 300 lbs. (which is about that due to a vigorous jerk), the chain ring to be 3 inches diameter and the hub flange 1¾ inches diameter, if the average final spoke tension be 80 lbs., it is easy to show that the hub will twist $7{\cdot}35^{\circ}$ relatively to the rim.

In a tangent-spoke wheel the hub must also turn relatively to the rim, but the angular movement is far less. In this case torque has the effect of increasing the tension on half the spokes and decreasing it on the other half. Reverting to Fig. 1, if the initial tension on $A\ B$ and $C\ D$ be t and the added and subtracted tension be p, the torque due to—

$A\ B$ will be $(t + p)\ r$, and to
$C\ D$ will be $(t - p)\ r$.

The difference of these is the resultant torque due to this element—

$$\therefore \text{ Total torque} = \frac{N}{2} \times (tr + pr - tr + pr)$$

$$\therefore T = N\, p\, r.$$

Which is independent of the initial tension t provided $(t - p)$ is a positive quantity.

If the tangent circle be of the same diameter as the flange in the previous case, it is easy to show that, for fifteen-gauge spokes elasticity 10,000 tons per square inch, the twist of the hub for the same push as before will be $0 \cdot 11°$, or about one-seventieth that with radial spokes. This greater rigidity in torque transmission places the tangent-spoke suspension wheel far ahead of both radial compression and radial tension wheels. It has long been universally used for bicycles and motor-bicycles, and is now enjoying unrivalled popularity in its application to motor-cars.

The radial wheel has to be subjected to great radial tension or compression in order to impart the necessary torque rigidity. In the tangent wheel the necessary torque rigidity can be attained without imparting excessive radial rigidity. As a result of this the tangent suspension wheel can be made capable of absorbing shock. A comparison of a suspension wheel with a section of a tyre will bring this out more clearly.

Suspension Wheel and Tyre Segment Compared.

The deformation of a tyre by load is resisted because the radially-acting air pressure puts the tube and cover in considerable tension. The rim of a suspension wheel is the reciprocal of this, being in compression due to the radial components of the spoke tension. The rim flattens like a tyre under load or shock, the radial tension in the one case acts like the air pressure in the other; the greater the tension the less the rim flattens, and the less the tension the "softer" is the wheel.

Wheel-building is the counterpart of tyre-inflating, and the art produces its best when sufficient tension to produce torque rigidity is combined with conditions that develop in the wheel a maximum cushioning effect. Such a wheel, by co-operating in the duties of the tyre, lengthens its life and lessens its liability to wear, cuts, and punctures. To obtain maximum cushioning from a wheel of this type, moderate spoke tension needs to be combined with a flexible and resilient rim and thin spokes. This in its turn implies not only careful choice of materials, but appropriate design to neutralise the reduction of resistance to torque perpendicular to the plane of the wheel entailed by lightening the rim. Both the wheels of antiquity, modern artillery wheels, and wheels for motor-cars, owe much of their lateral strength to the high moment of inertia of their heavy wooden felloes, the disadvantage of which is their inflexibility and consequent inability to absorb shock. The Rudge-Whitworth wire wheel for motor-cars (Fig. 2) is the first wheel in which these requirements were adequately met. This is done by making the outside spokes, that are much dished, enter the rim near its edges and not at its centre, as was formerly considered correct. In this way members are provided to oppose the twisting of the rim due to sideways shearing of the tyre when rounding corners.

It is only fair to add that this method of spoking has the effect of localising the bending stresses, due to the pull of the tyre bead, in the edge of the rim. This is met by strengthening the rim bead, which at the same time strengthens the whole wheel very considerably.

There is another point of similarity between the wire wheel and a tyre segment. If the radial compression on tyre walls gradually decreases owing to air escaping from the stressed condition, the flexed part of the tyre will be increased, and a point arrives at which this has to be neutralised by inflating. Similarly, if the spoke tension of the wire wheel should fall the flattening of the rim would increase, and might even reduce the spoke tension to zero.

Fortunately, solids are more easy to manage than gases, and by employing spokes of high elastic limit, and by cold working the metal of the hub shell round the spoke heads, and of the rim round the nipple holes by hammering and bulging (coupled, of course, with proper design and materials), the vibration elastic limit above which permanent escape and loss of tension would occur, is made so high that after a slight initial bedding the ordinary stresses are insufficient to "soften" the wheel. In any event, the spoke tension can be adjusted readily. It is not to be supposed that even a wheel of this advanced type is capable of absorbing as much shock as a tyre. The air pressure in the inner tube of a motor tyre ranges usually from about 60 to 90 lbs. per square inch, but the corresponding normal pressure on a Rudge-Whitworth wire wheel rim ranges from about 150 to 200 lbs. per square inch. This, combined with the fact that the rim is not nearly so flexible as a tyre cover, accounts for its inferiority to the tyre as a shock absorber, though the much larger diameter of the wheel operates in the other direction. Large

diameter wheels—like large section covers—are, *ceteris paribus*, better shock absorbers than small ones. The superiority of this type of wire wheel as a shock absorber, compared with compression wheels with radial wood spokes, is a matter of actual experience as well as of conjecture, and is noticed in their more constant contact with the ground under similar conditions of use.

spokes transmitted the drive. In the present Rudge-Whitworth wire wheels, to prevent the stresses rising too high when rounding corners or when skidding, the wheels are dished and the outside spokes are relieved of the whole or greater part of their share in transmitting drive. This is done in some types by making the hub of much larger diameter at the end near the car than at the other end. As a result of this the

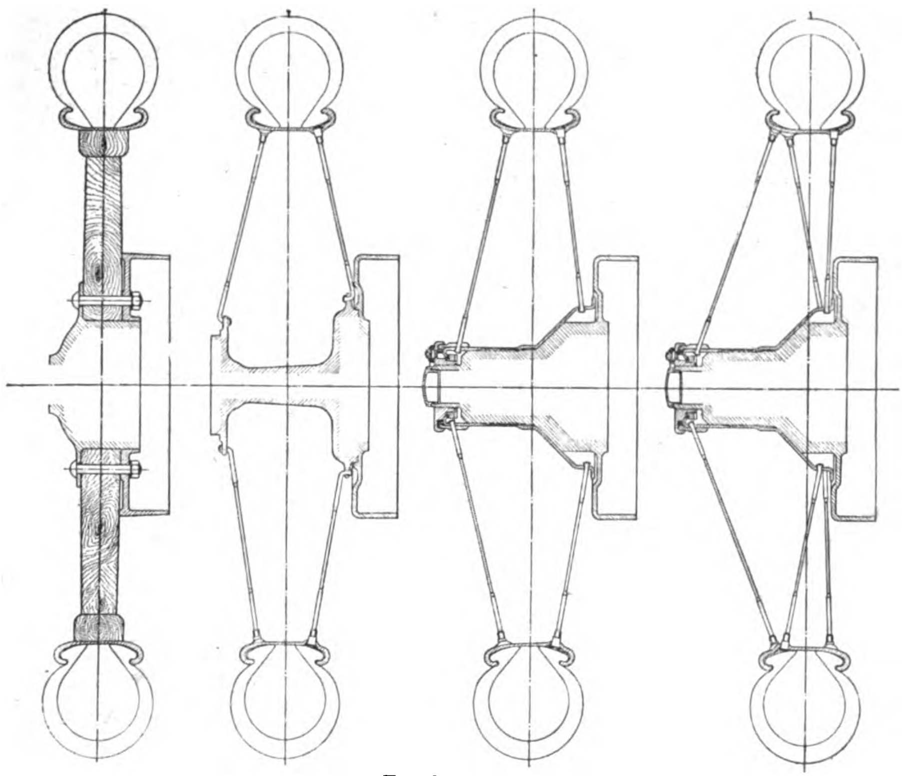

FIG. 2.

Fixed wood wheel. Fixed symmetrical wire wheel. Rudge-Whitworth patent detachable wire wheel, patent dished construction, double-spoked. Rudge-Whitworth patent detachable wire wheel, patent triple-spoked construction. Regd. No. 541916.

displacement of the inside spoke heads under torque is greater than the displacement of the outside spoke heads, the ratio of the displacement in the direction of the spokes (and therefore of the added tension) being the ratio of the diameters of the circles to which the spokes are tangent. In other types the end of the hub to which the outside spokes are attached is revoluble, so no torque is transmitted by them and their whole strength is reserved for resisting side-thrusts.

Another departure from symmetry which secures greater strength for the inside or driving spoke cone is the employment of 50 per cent.

EVOLUTION OF THE MOTOR-CAR WIRE WHEEL.

The first wire wheels to be used for motor-cars were bi-laterally symmetrical like the front wheel of a bicycle. The spokes were headed and bent near the head through 90° (see Fig. 2). The holes in the hub flanges were drilled parallel to the axle, and the spokes threaded through these holes were attached to the rim by nipples screwed on to the other end of the spoke. But, as in living structures, so in engineering constructions, evolution brings gradual morphological differentiation of structure and further division of labour. In the early bi-laterally symmetrical wire wheels both inside and outside

more spokes inside than outside. In the hub shells the spoke holes are not drilled parallel to the axle, but perpendicular to it. This enables spokes bent through a small angle to be used; for instance, the inside spokes that transmit the drive are only bent through 45°, and this, coupled with a special way of producing the bend and careful scrutiny in the firms' laboratory, has enabled the strength at the bend to be increased from about 60 per cent. (with the 90° bend) to over 90 per cent. that of the body of the spoke. The outside spokes are bent through less than 45°, so the strength at the bend is still less impaired. Another improvement is the addition of another cone of spokes, making three in all, so that the drive is transmitted to both sides of the rim. The same device enables the point of contact with the ground to be more nearly under the bearing or steering knuckle (see Fig. 2).

I will next show you a diagram (Fig. 3) illustrating the fluctuations of spoke tension (or compression in a compression wheel) under some of the conditions of use, assuming that the rim is *not* flexible. When the wheel is jacked up, revolving does not appreciably alter the spoke tension, and it does not vary with time, so is represented by a horizontal line. When the car is in steady motion and free-wheeling the tension on each spoke will increase and decrease, the values following a cosine curve (as already explained), the X axis of which should be below the minimum points. The zig-zag illustrates the effect of a shock due to the wheel leaving the ground and falling back suddenly to its former condition. The dotted line shows the instantaneous condition of a spoke diametrically opposite.

In the next we see the variations in tension of the spokes of a driving wheel travelling straight; and the next shows the variations when the wheel is being driven round a corner. It is important to notice that the effect of the same shock is very different in the different cases, and depends on the instantaneous value of the spoke tension as well as on the position of the spoke in the wheel. The variation set up in a wood wheel will follow the diagrams pretty closely, but actual experiments with wire wheels show that the increment of tension due to load, torque, and load and torque combined, is not nearly so great as those diagrams indicate.

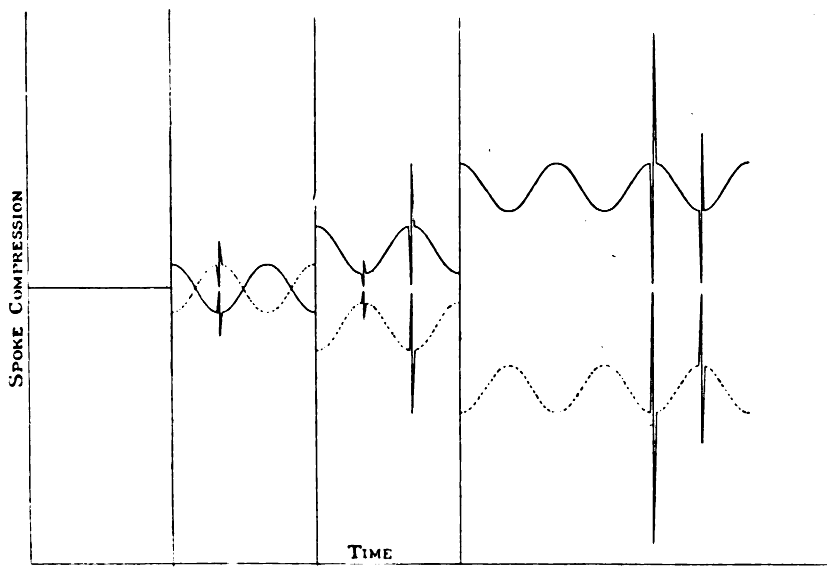

Fig. 3.

Experiments with Wire Wheels.

Fig. 4 shows a polar diagram of the tension on the spokes of a Rudge-Whitworth detachable wheel fitted with a tyre sustaining a load of one ton. About one-quarter of the spokes have their tension relieved, but the others experience nothing like the same increase, and it is distributed fairly evenly all round.

To test the effect of combined load and torque the pull was applied to a dummy tyre made of iron, so that its line of action did not pass through the centre of the wheel. By varying the distance between the wheel centre and the line of pull the ratio $\frac{\text{load}}{\text{torque}}$ could be varied at will. In this way tests imitating all sorts of

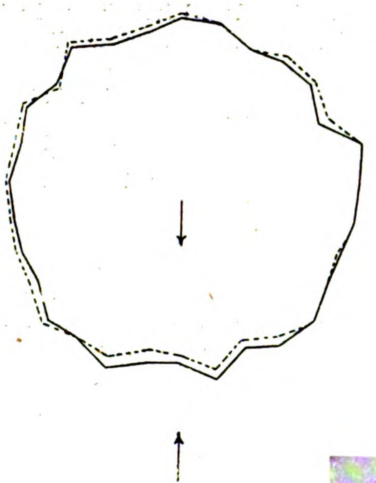

FIG. 4.

conditions of road surface, car load, and horse-power engine have been carried out.

Fig. 5 shows a polar diagram for a wheel having the same number of outside and inside spokes, the outside spokes of which transmit their pull to the hub and not to a revoluble ring. The outer dotted line indicates the initial tension on the inside spokes, the inner that on the outside ones. The dots show the effect on the tension of the combined load and torque. In this test the inner hub, hub-shell nipples, and rim are all tested, and the results demonstrate beyond controversion the enormous strength of these wheels for forces and couples

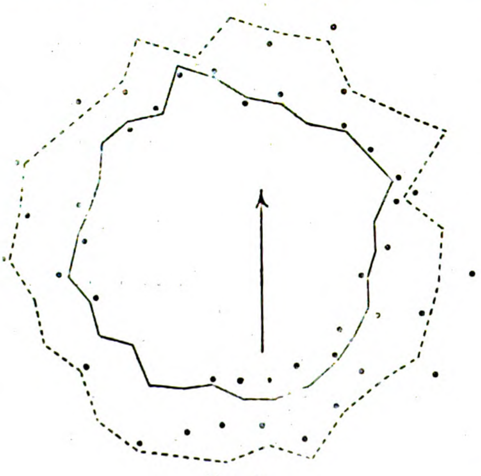

FIG. 5.

in the plane of the wheel. The point to which I would particularly call attention is the great advantage of a flexible rim which, as these results show, quite obviates the high tensions or compressions which would otherwise obtain, and which would prove so destructive every time the wheel was jerked off the ground.

In addition to determining the effect of load and torque, separately and combined, we have subjected both wood and wire wheels to a side-pull applied at the rim or to a dummy tyre. Fig. 6 shows a Denison testing-machine adapted to imitate the stresses set up in rounding a sharp corner at very high speed or in a bad side-slip. The results of some of these tests will be seen

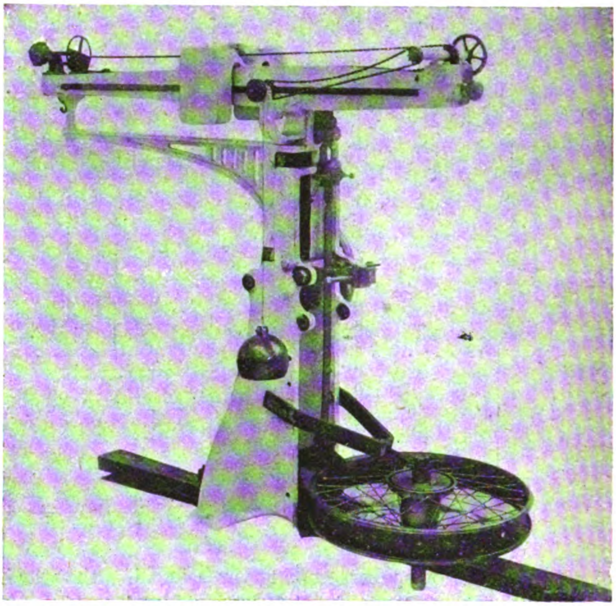

FIG. 6.

in Fig. 7. In nearly every instance the deflection of the wood wheel for the same pull is greater, and in every case the wood wheel sustained permanent damage at a lower pull than in the wire wheel. The same applies to the sheet-steel wheels. The arrangement of the spokes in the Rudge-Whitworth wire wheel has been the subject of careful design and experiment. Fig. 8 shows the results of some of these experiments, and makes it clear that the strength attained, even with precisely similar rims, hubs and spoke material, depends greatly on the design selected. These tests have given valuable data as to the best designs and materials for the rims, spokes, and hub shells. It does not follow, however, that designs and materials proved suitable for withstanding a steady force are also suitable for

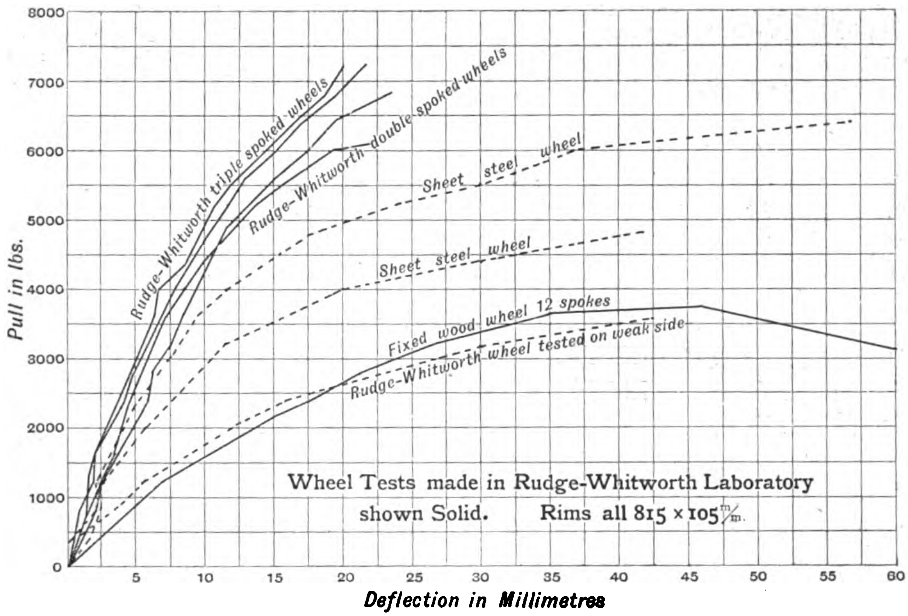

FIG. 7.

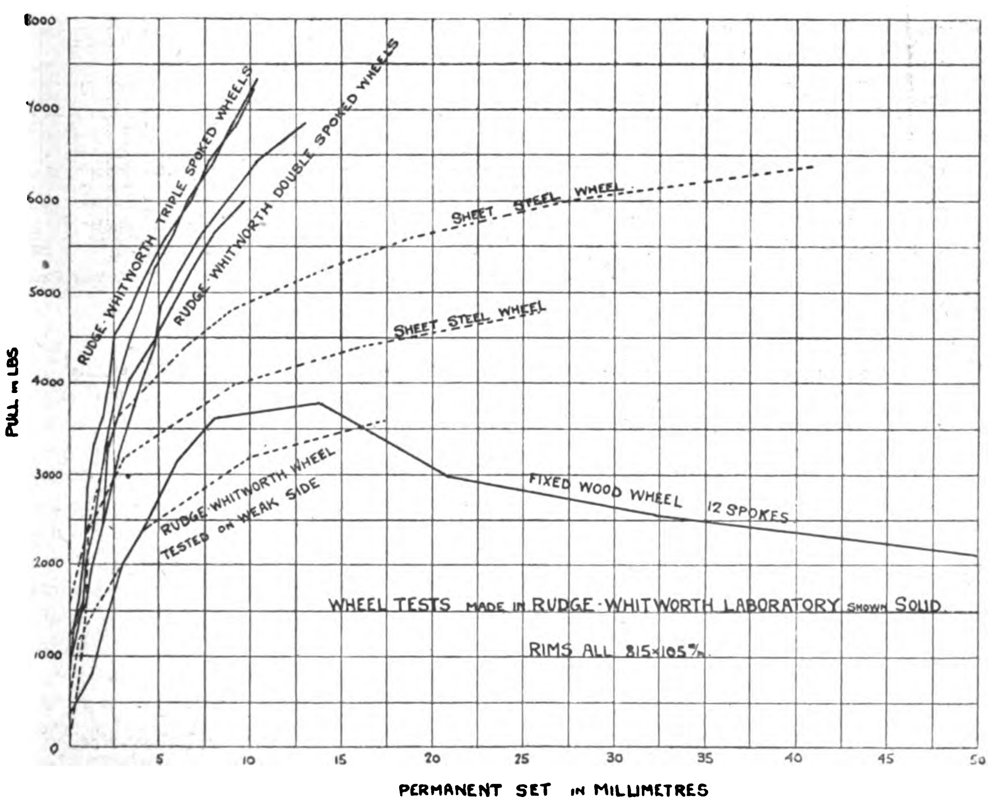

FIG. 7 (continued).

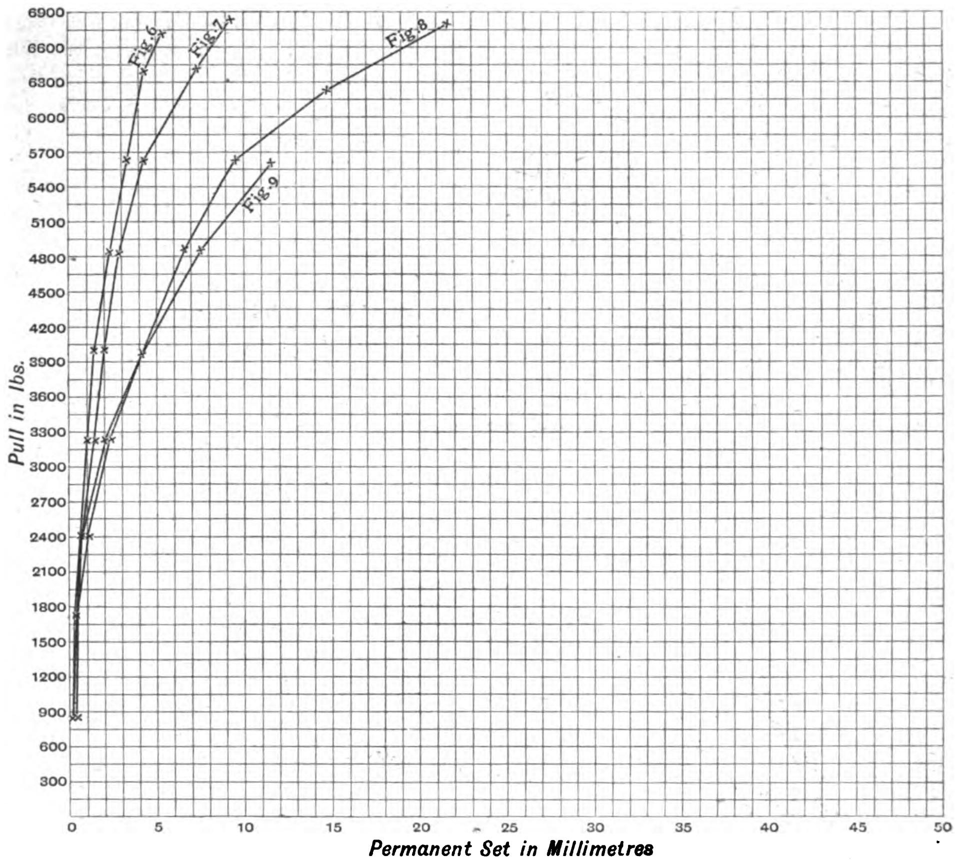
impulsive forces, so the various types of wheel have been investigated under impact.

The next slide shows the impact pendulum ready to be released against the top of the



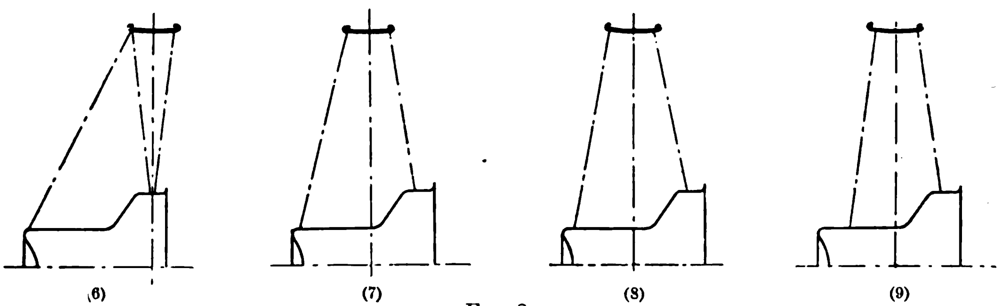


FIG. 8.

rim of the tyred wheel. The length of the pendulum is about 12 feet and the bob weighs nearly a quarter of a ton. In some tests increasing blows were applied to the same part of the wheel, in others a moderate constant blow —*e.g.*, 200 foot-lbs.—was applied at successive points on the rim eleven-thirtieths of the whole circumference apart. Fig. 9 shows characteristic diagrams for wood, wire and sheet-steel wheels subjected to increasing blows at the same place; and Fig. 10 shows the results of testing wood and wire wheels with similar blows, the wheel

being turned eleven-thirtieths of the way round after each blow.

The question will probably suggest itself as to whether a motor-car wheel is ever called upon to stand side-thrusts and blows as great as those represented by the upper part of Figs. 7 and 9. The magnitude of the stress depends in every case, not entirely, but primarily, on the force that the ground can exert on the wheel. For instance, the forces that turn a car round a corner reside in the ground. It is quite a mistake to suppose that the driver at the steering-wheel really steers the car; the path followed may be *indicated* by the steerer, but it is *dictated* by the ground. The most the driver can do is to turn the wheels into such a position that, if the ground permits, the forces developed under and near the wheels will alter the direction of the car to the desired extent.

The stresses set up when rounding corners without skidding have been very fully investigated by J. V. Pugh (*Autocar*, 1906, pages 910 and 948). When travelling at twenty miles per hour round a curve 30 feet radius, the side-thrust on an outside wheel, at the tyre, may be as much as 1¼ times the load on the wheel when travelling straight. When skidding, the side-thrust may be considerable, not only when stopped by a curb-stone, but also when the side-slipping wheels are arrested by a dry, sandy, or rough part of the road.

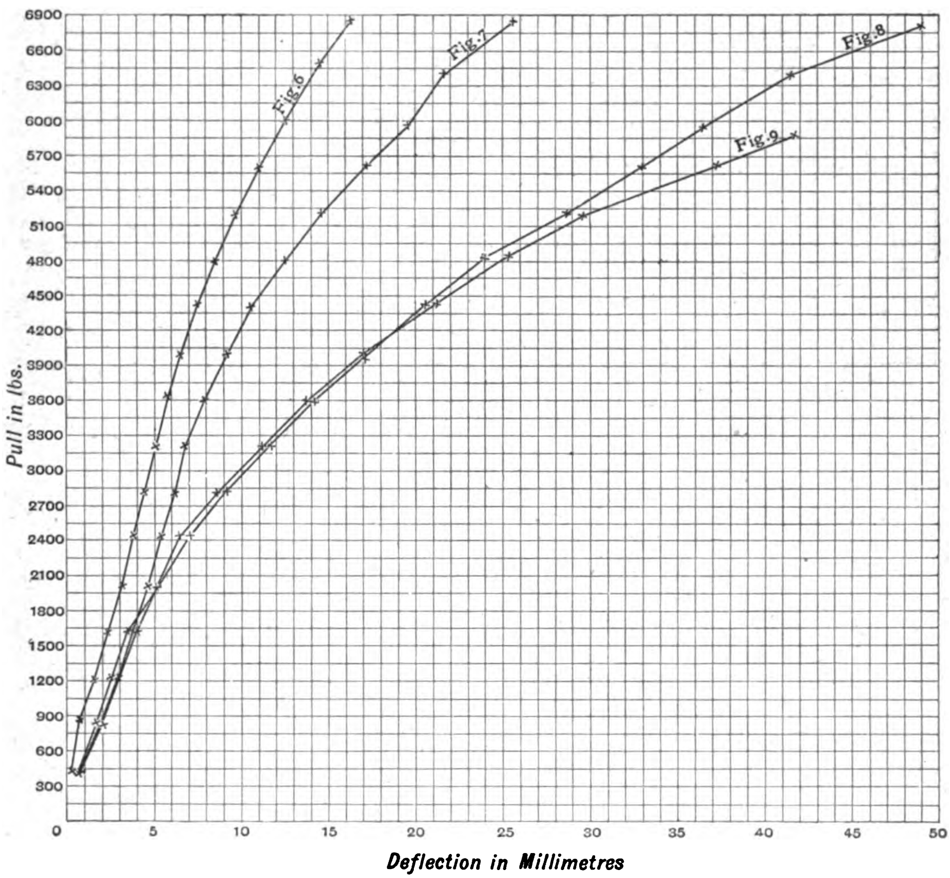

FIG. 8 (*continued*).

If the rear wheels of a car weighing one ton skid sideways at a corner, and are brought to rest by the outer wheel running on to a dry, rough, or sloping part of the road, and if two-thirds of the load is borne by the rear wheels, and they attain a sideways velocity of five miles per hour, and stop after sliding three inches beyond the slippery part, then, taking moments

about the front wheels, the retarding force is

$$\frac{2\,W}{3} \cdot \frac{v^2}{2\,gs} = \frac{2}{3} \cdot \frac{2240 \times 53{\cdot}8}{64 \times {\cdot}25}$$

= 5020 lbs. approx. on one wheel.

On a smooth surface, even if dry, the ground would not exert so great a force on the tyre,

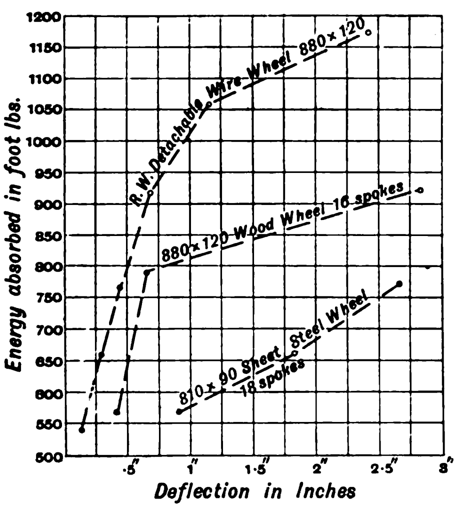

FIG. 9.

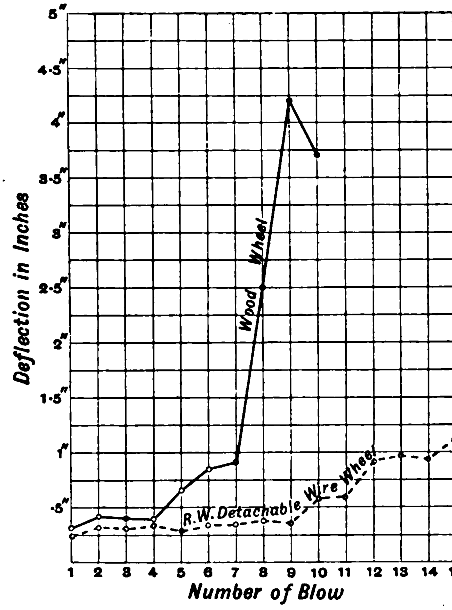
but when rough and sloping, even greater forces can be exerted.

Having now shown the superiority of wire wheels as shock absorbers, under load and torque, under side torque driving and shock in a direction vertical to the plane of the wheel, I will give a brief outline of the tests that are regularly carried out in the Rudge-Whitworth research laboratories to maintain the standard of excellence. It will, perhaps, be convenient to start with the hub where the torque is applied, and proceed *via* the hub shell, spoke heads, spokes, nipples, and rim to the tyre.

Inner Hubs.—The inner hub, which is of steel, is keyed on to the axle and has a series of keys which engage with similar slots milled inside the hub shell (Fig. 11). The material is analysed; its tensile strength, elongation, and contraction determined; and, as its main duty is to resist shear and transmit torque, test pieces are clamped in a vice and struck by an impact pendulum. From the sectional area of the piece, and the difference between the arc traversed after impact and the arc when there is no test piece in the vice, the energy absorbed per square inch can be calculated. The results are reported diagrammatically.

Definite limits have been arrived at for tensile strength, elongation, and impact resistance, above which all samples must be before acceptance. The strength of the threaded end is important, for it is a lock-nut screwed on to this that keeps the wheel on the car. The strength of the hub ends is regularly "proofed" by screwing the hub to be tested home into a



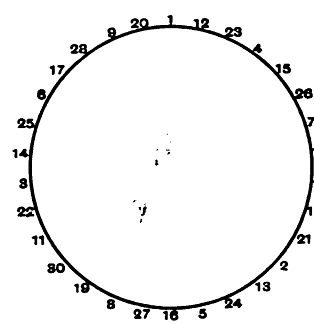


FIG. 10.

fixed lock-nut and applying a very considerable torque graded to suit the size of the hub, and well up to the maximum ever likely to be applied.

Hub Shells.—These are drawn from sheet steel, and some types are all in one piece. About fourteen drawing operations, each followed by careful annealing, are required. Quite apart from the stresses the hub is subject to in use, this mode of manufacture itself exacts a very

special quality of steel, and when it is remembered that a moderately-high elastic limit is required in the finished shell to resist the bursting stresses and the pull of the spokes, and that high elastic limit means greater internal stress and the formation of more brittle amorphous constituent during a given draw, it will be understood why the problem of successful manufacture was only solved after a long series of experiments on different steels, followed by the very closest supervision to maintain the uniformity of the steels selected.

Every consignment is analysed and tested for tensile strength, yield point, elongation, contraction, and resistance to impact, not only as received, but after heating under conditions as to time and temperature similar to those obtaining during an annealing operation.

Every consignment is also microscopically examined for flaws, manganese sulphide, size of crystal grains, form of carbide, etc. As would be expected, the behaviour in the drawing press is closely related to the elongation and contraction. Much depends also on the distribution of the pearlite and granules of cementite. One with a core rich in pearlite, but with decarbonised surfaces, may give much the same analysis as a steel with granules of cementite uniformly distributed throughout the ferrite, but the results in the press are very different. All reports on steels are typed on squared paper, and include a diagram (Fig. 12) embodying, as far as possible, all the experimental results that affect the mechanical properties. For instance, *A C* represents the tensile strength and *A Y* the yield point in pounds per square inch of a sample of motor hub-shell steel, *A B* its breaking elongation, and *A F* its contraction per cent. The area, *A B C*, represents in diagrammatic form the energy required to break one square inch of the steel by tension. Likewise, the area *A B E F* represents the ductility of the steel. *D B* is obtained by dividing the energy in inch pounds per square inch absorbed in breaking by impact, by half the breaking elongation, so *A B D* represents the energy per square inch required to break a test piece 1 inch by 1 inch. The corresponding triangles, etc., on the left, refer to the steel after annealing.

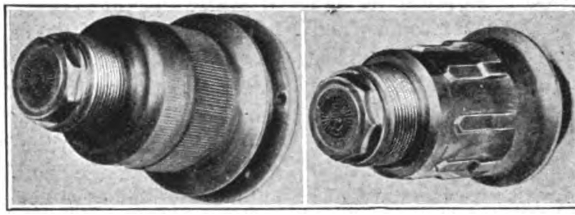

FIG. 11.

The rectangular areas, marked *C*, *P*, and *F* are calculated from the results of analysis, using the formulæ suggested by Campbell (*Journal of the Iron and Steel Institute*, 1904, No. 2, page 21), modified to suit this class of steel. The area *C* represents the part of the tensile strength contributed by the carbon (or more accurately by the carbides and their distribution), and that marked

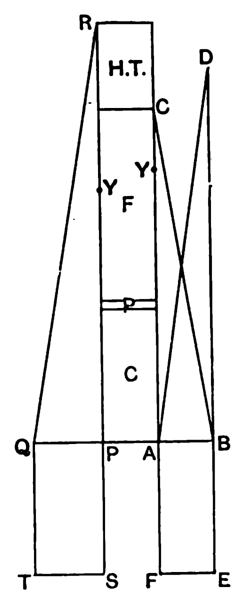

FIG. 12.

P the part due to phosphorus. In this instance the manganese was not present in sufficient quantity to add to the tensile strength. The area marked *F* represents the tensile strength due to ferrite alone in this class of steel, and the rectangle, which is the difference between the observed and calculated tensile strength, represents the portion of the tensile strength added by the heat treatment and annealing.

Not only the hub shell, but also the spoke ring and the withdrawal ring that go to complete the outer hub are analysed, tested, and microscopically examined in a precisely similar way. To check the correctness of the dimensions chosen for the hub shell, the finished shell was tested under torque, as already described, and under spoke tension — (1) by inserting spokes and pulling them in a Denison machine, and (2) by building up into a wheel and steadily increasing the tension (which was measured as described below) until permanent deformation occurred.

To ascertain the resistance of hub shells to impact, wheels built up with experimental shells are tested with the impact pendulum. To check the care with which the annealing is done, tensile tests and analyses are made on pieces cut from the finished shells to see that the carbon is not "burnt off," and that the elastic limit is not lowered.

Spokes.—Though the great care exercised in choosing and maintaining the quality of hub-shell steel is necessary, still greater is that necessary in the choice and maintenance of suitable material, structure, dimensions, and design for the spokes. This is required because of the variation of tension to which they are subjected. An alternating tension test is used to subject them to variations like those experienced by a spoke in a wheel. In addition to this, all consignments of spokes are tested for tensile strength, elongation, and contraction, near the head and on the swaged part, and a longitudinal median section is examined microscopically to see if the pearlite grains have the dimensions that have been found most suitable. The next slide shows micro-photographs of longitudinal median sections of a motor spoke which did good service in the Isle of Man Tourist Trophy Races, and of a bad motor spoke which broke in use. The microscope also detects undue internal strains set up during heading. Occasional analyses are made.

To check the accuracy of the initial tension on the spokes, wheels are taken at random from the stores and the tension on each spoke is measured. To do this two spokes, one outside and one inside, are fitted into a hub, nipples screwed on, and a pull applied to the nipples in the Denison testing machine. The pitch of the notes emitted at different tensions by the spokes when twanged is then compared with whistles and tuning-forks. In this way a scale of tensions is found for each spoke which corresponds to a definite scale of whistle notes. The spokes in the *wheels* are then twanged, and their pitch—and therefore tension — ascertained by these whistles. The spoking machine now used in building these wheels goes far to ensure uniformity of tension.

The microscope has proved useful in controlling the spoke threads. The threads on Rudge-Whitworth motor (and cycle) spokes are not cut in, but rolled out of the metal. In this way the diameter and strength obtained at the base of the thread is greater, for the rolling process jumps up the metal, strengthening it by the cold working it gets. With the microscope the actual displacement of the metal can be accurately followed by observing the positions taken up by the pearlite grains, and the degree of cold working at various parts of the thread can be gauged. Lines of weakness can be detected at once, as also imperfection in the outline.

Nipples.—The material from which the nipples are made has to be of high tensile strength. Consignments are tested for tensile strength, elongation, and contraction. They are also analysed and occasionally tested with the impact tester. Of course, nipples and all other parts of these wire wheels have their essential dimensions gauged by a large staff of expert viewers, but as this work—though scientific in so far as "science is measurement"—is really outside the work of the laboratory, it is omitted from the present account.

Rims.—The stresses to which rims are subject are complex. As already pointed out, load bends the rim, flattening it where the load is borne. This varying flexure will spread to the rim bead, making it bend and unbend to a slight degree. Another and more important cause of the bead bending is due to the tendency of the cover to pull away. This is proportional to the air pressure and the radius of the air tube section. For a tyre pumped up to 90 lbs. per square inch, and with an inner tube 4 inches in diameter, the force on 1 inch of the bead and perpendicular to it will be 180 lbs. This force will vary in magnitude, being greater near the ground and when rounding a corner, and will call into play transverse strains.

In testing rims, therefore, a section one inch wide is taken and tested by applying a pull to hooks made to imitate the bead of a motor tyre, and the elastic limit and yield point recorded. The tensile strength, elongation, and contraction are determined of pieces cut transversely as well as lengthwise, and the rims are occasionally analysed, tested for resistance to impact and microscopically examined.

Tyres.—Although tyres are somewhat outside the limits indicated by the title, the influence of the wheel on the tyre is too close to omit reference to them. One characteristic feature of wire wheels that contributes to reducing the tyre depreciation, viz., power of absorbing shock, has already been mentioned. There are others. The rise of temperature of tyres after a quick run is familiar to all. The hand cannot be held on the treads, cold water is converted into clouds of steam, and actual measurements on racing car tyres (*Automobilia*, August, 1908) show that at 135 kilometres per hour the temperature reached by the cover and air tube were respectively 132° C. and 96° C. This is in part due to friction between the ground and the tyre tread just as it is leaving and retouching the ground owing to the inequalities of the road surface, etc., in

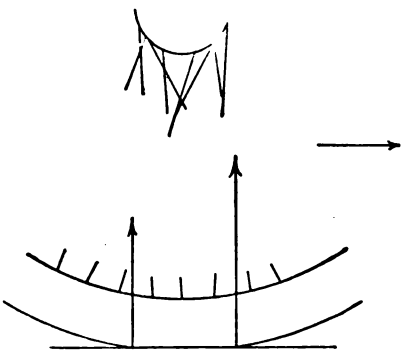

FIG. 13.

part to friction in the canvas or fabric, and in part (and probably in greater part) to the fact that when the stress in rubber is considerable, and its temperature is a few degrees above 8° C., both extension and compression cause rise of temperature (Todhunter and Pearson's "History of Elasticity," vol. ii., part 1, page 477). As the temperature of the tyre rises, the tensile strength of the rubber diminishes, and the energy stored in the rubber and not returned on leaving the ground increases rapidly. This not only leads to further rise in temperature, but to further softening, greater elastic hysteresis, and to increased resistance to the forward motion of the four wheels. This is easily seen from Fig. 13. From measurements made by the Palmer Tyre Company, the loss for one tyre may be as high as one-half horse-power. The bearing of this on the construction of wheels is that the steel rim, which conducts much of the heat away, is, in the case of a wire wheel, able to leave its heat behind, whereas the wood felloe (which has only one fourteen-hundredth the conductivity of steel) insulates the rim of the wood wheel just where cooling is most needed. Bearing in mind that the cost of rubber tyres is something like 23 per cent. of that of the raw material used in a 14 horse-power live-axle motor-car, the urgent need for something to mitigate the cost of their upkeep can readily be grasped.

The cost of tyres, including one spare, for such a car varies, of course, but taking it at £40 per set of five, their cost is about 13 per cent. of the finished car. Rudge-Whitworth wire wheels for such a car would cost (not including inner hubs) about £17 10*s*., 5·8 per cent., and, needless to say, the depreciation due to use is far less on this 5·8 per cent. than on the 13 per cent. due to the tyres. Unfortunately, I have no figures comparing the wear of tyres on Rudge-Whitworth wire wheels with the wear on other wheels, but the impression that wire wheels really do save the tyres is steadily gaining ground among motorists.

SOME OTHER MODERN WHEELS.

The defects and cost of tyres have led to a quickening of interest in spring wheels, and many attempts have been made to obtain sufficient resilience by employing springs in place of air enclosed in rubber.

In 1906 a spring-wheel contest was held in France. There were thirteen entries, two cars forfeited, and one was put *hors de combat* by an accident while landing at Boulogne. Of the ten that started, six depended for their resilience upon the application of rubber, and four used metal springs only. The only three that finished the 1,300 miles were of the rubber type; the metallic springs broke down early.

The chief defect in spring wheels, and one that is inherent in the system, is the considerable mass of steel that is required to give the necessary resilience. This is consequent on the numerical value of the elasticity of steel and the high factor of safety necessary under alternating stress.

The greatest amount of energy that can, without permanent set, be absorbed by a spiral spring of solid wire weighing 1 lb. is about 50 foot-lbs. This figure can be doubled by employing a hollow spiral tube with thin walls. A straight wire of spring steel weighing 1 lb. will safely absorb 60 foot-lbs. The shocks due to irregularities and obstacles on the road may reach many thousands of foot-pounds, and since the energy to be absorbed varies as the

square of the velocity, it is obvious that for high speeds enclosed air, which will take up a practically unlimited amount of energy, is much more suitable than springs.

In the Reid-Reikie spring wheel there are sixty-four spiral springs, each weighing 3 lbs., or nearly 200 lbs. for springs only in each wheel, and each spring has a free radial movement of only about one-quarter inch.

An improved spring wheel capable of transmitting drive to the outer rim was invented by the Hon. R. C. Parsons, and many other types are to be found in the publications of the Patent Offices.

have spokes made of flat steel-plates bolted to flanges on the rim. Usually the spokes are on two cones intersecting between the rim and the hub.

The Sankey wheel for motor-cars is made of sheet steel and looks much like an artillery wheel. By means of a number of stamping and drawing processes, a plain disc of steel is moulded into the shape of a half wheel. These halves, welded together by oxy-acetylene, form a light wheel which, as shown by the diagrams of tests exhibited, possesses considerable strength.

Fig. 14 shows a line-drawing of hydraulic

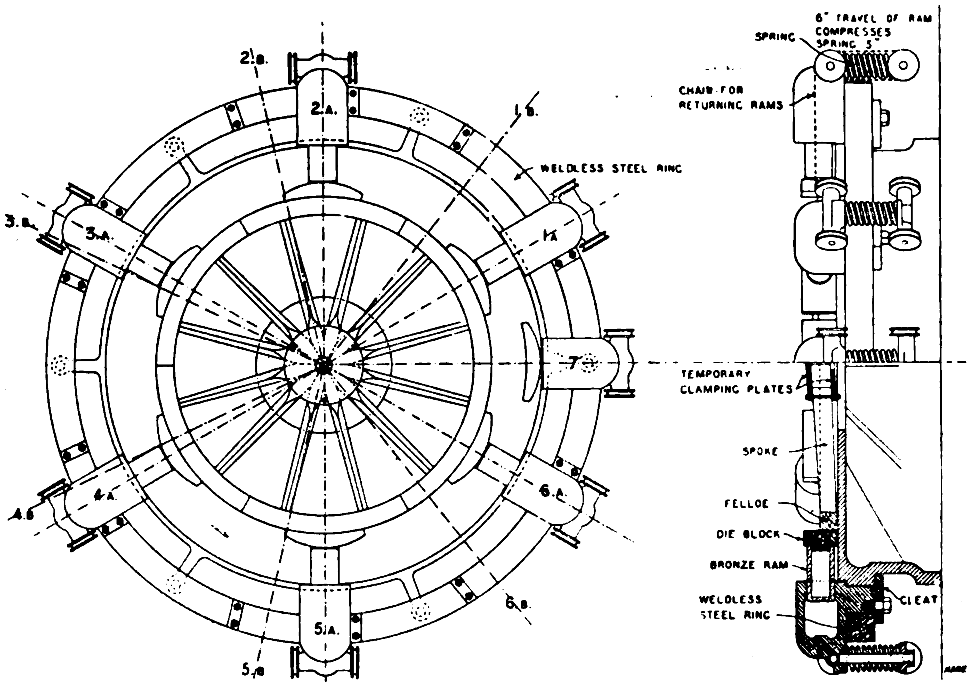

Fig. 14.

Railway waggon wheels are now usually made of steel. The flanged tyre is rolled from a punched billet and shrunk on to the wheel. This is usually of cast steel, and is forced on a forged steel axle.

The next slide shows two types of steel wheel made by the Shrewsbury and Challiner Tyre Company. These are built up by welding H and T section girder-steel spokes to steel flanges at the centre and steel rims by means of the oxy-acetylene blow-pipe. When T section steel is used for the spokes they are arranged on two cones intersecting at the rim. The wheels used on the London Omnibus Company's motor omnibuses are of cast steel.

Thorneycroft truck and traction engine wheels

rams used for building wood wheels. A wheel-setter, built much on these lines, is used at the Royal Woolwich Arsenal, where the practice is to heat the iron tyre, but not to red heat. The degree of compression produced by the contraction of the tyre depends on the yield-point of the metal, and this is very low in red-hot iron; consequently, after putting on the hot tyres, the rims are used to compress both tyre and wheel, the final tightening being performed by the contraction of the rim.

I will now conclude by showing on the screen a number of photographs illustrating the appliances used at the Rudge-Whitworth works for making and testing their wire wheels.

DISCUSSION.

The Chairman said it would be agreed that the paper was a very interesting one, and had covered a great deal of ground. The references to the ancient history of the wheel had been particularly interesting. It was just as well that Mr. Heathcote was not a consulting engineer to Pharaoh; if he had been, the Israelites would have had a bad time. He was sorry the paper did not deal with the manufacture of locomotive wheels, as it was a most beautiful industry: the way in which the spokes were welded together was quite a work of art. Many of those wheels were now cast in steel, so that what was to him a very beautiful manufacture was now passing away. The wire wheels were a beautiful piece of work, but he did not think the author had quite made out his case with regard to the strength of them against side shocks, as compared with wooden wheels. The wheel was designed in a dished form, i.e., the outer spokes were attached to the hubs, which were further away from the rim of the wheel than the inner spokes, and in that way there was a better angle of tension. But if such a wheel got into a tramway or other rut, the force was exerted outwards as well as inwards, and the wheel was not so strong to resist a shock of that sort as it would be if the wheel came up against the kerbstone. But in a wooden wheel the spokes were as strong one way as the other, so that he thought the wooden wheel had scarcely had a fair chance at Mr. Heathcote's hands. He (the speaker) did not think wooden wheels were dished to increase strength. One saw waggons with their wheels dished and the axles bent, which was an ingenious contrivance to ensure the wheel always pressing against the inner collar on the axle. In that way the backward and forward movement of the wheels on the axles, which was sometimes heard in a cart, was got rid of. The tensile tests on the spokes of the wheel mentioned by the author were evidently carried out while the wheel was in motion; consequently the apparatus for testing must be in motion too. He would be glad to hear how that was done when Mr. Heathcote replied. Wire wheels were very pretty, but if they went wrong in a country place where there were no Rudge-Whitworth shops, there would be delay and difficulty in getting them put right; whereas in most places there was a wheelwright who could repair a wooden wheel. He would be glad to hear what was the weight of the wire wheels compared with that of the ordinary wooden wheels, and also those manufactured by Messrs. Sankey, which were now being largely used, especially for cars going abroad, in consequence of wooden wheels not standing high temperatures.

Mr. H. M. Wyatt reminded members that when he recently read a paper before the Society, he touched on the subject of wheels. It was a very important matter in connection with the heavier kinds of motor transport, and especially in countries where the motor-car for transport was only developing. The wheels of cars running in this country were not usually of sufficient diameter to meet the requirements of the potential user in less developed districts. The wheel should not be dependent on complicated contrivances which required the constant presence of an expert. The question was still further complicated by the fact that the increase in the size of the wheel meant an increase in the size of the solid rubber tyre to go on the wheel; and if the user had to pay more for the tyre, he was less likely to take what the manufacturer offered him. He would be glad to know what was the cost of these wheels compared with that of other wheels which served a similar purpose; for instance, the cost of the wheels for a Daimler omnibus compared with the Sankey, or the Shrewsbury, or the Challiner. In regard to weight, he did not know that Mr. Heathcote could show figures which proved the superiority of the wire wheel over all others in this particular. It seemed that a very heavy expense in connection with wire wheels was the cleaning. To clean 500 pairs of wire wheels would be a much greater task than cleaning a similar number of sets of pressed or cast-steel wheels. He could see the advantage of the wire wheel for certain types of work, but was there any limit? If so, he would be glad to know where it lay. In the wheels exhibited, the length of the hub was greater compared with the diameter of the wheel, and if the same kind of wheel were designed for a tractor or other large vehicle, requiring five feet across, the length of the hub would be so great that it would affect the total overall width of the vehicle so much as to make it, possibly, unsuitable for use. The side-strains in those big wheels would have to be met, and he could see no way of doing that, except by lengthening the hub. The cross-strain, from skidding, etc., would also have to be met, and the ideal way of meeting that would be by spokes projecting horizontally, inwards and outwards from the rim of the wheel, parallel to the axle, and there would have to be discs to support the outer ends of the spokes of the size of the wheel itself. So one could eliminate spokes altogether, and get a disc wheel. It was partly for that reason he thought there must be some limit to the weight that could be borne by wire wheels.

Mr. E. G. Beaumont remarked that the reader of the paper said that the life of tyres on the wire wheels was longer than that of the wooden one; and the suggestion seemed to be that this was partly due to the fact that they were spring or resilient wheels. That was a view which he (the speaker) scarcely shared, and he would be glad to know whether it was due to the greater resiliency of the wheels, or to their increased lightness. The weights given (for four wheels) were, he believed, 149 lbs., and 179 lbs. respectively. That difference alone would go far to account for the greater durability of the tyres. Where other metal wheels had been used, and the

number of spokes was less, there had been considerable difficulty when fractures occurred at the junctions of the spokes with the rims; and it had only been by much strengthening of the junctions, or by adopting more spokes, or spokes of a form which had more than one junction with the rim, that the wheels had been made to stand. In the early days of the Michelin tyre that was a difficulty, and it was interesting, as the blows which led to the fracture were delivered through the pneumatic tyre, which one would look upon as the weaker part of the wheel. With regard to the author's statement that it was possible for a force of 5,000 lbs. to be delivered to the wheel from the road, that was to him a surprising figure, because the limit of effort would be set by the adhesion of the tyre on the road, and that was always considerably less than unity. The temperature rise in the wheels of recent cars was interesting. There was only a small figure of horse-power loss as the result given by the Palmer Tyre Company; one-half horse-power loss was mentioned. He (the speaker) had made similar calculations of temperature rise in different cases, and had found that loss 5 per cent. of the power in some cases. He asked whether the author had figures of that nature, or whether he had made similar calculations. The difficulty of cleaning the wheels had been mentioned, also the destruction of the wheel by corrosion. The latter he did not regard as of much consequence, as it could be dealt with, but the cleaning did seem to be a difficulty. With regard to the dished agricultural waggon wheel, there was an example where the axle was not only inclined downwards so as to ensure that the wheel should hug the inner side of the axle, but also was forwardly inclined for the same reason, so that even when there had been wear, it still had no tendency to drift away in the direction in which it would run off the axle.

Mr. JOHN PUGH said the lecture had been a very interesting one, especially in its historical treatment. And he was very glad the paper took a broader view than the particular trade which Mr. Heathcote was interested in. Wheels were the most fundamental example of what mankind had done. In Nature there was nothing of that kind for locomotion; the invention of wheels was entirely man's work. Ordinary modes of locomotion were jerky; even the motion of the horse was so jerky that riding it was recommended for cases of torpid liver. Where the animal had more legs, as the centipede, though the average general motion seemed more regular, it was yet made up of a series of jerkings forward. The time limits made it necessary for the lecturer to confine his remarks to wheels which touched the ground; but even in other spheres of human activity, civilisation had been marked by a departure from reciprocatory motion and going on to rotation instead. The turbine was a case in point, the advantages of which were well expressed when one remembered that the peripheral velocity of turbines varied from 15,000 to 60,000 feet per minute; whereas in racing motor-cars the highest recorded piston speed was about 4,000 feet per minute. With regard to the weak and the strong side of the dished wheel, the wheels his (the speaker's) firm were marketing were stronger from their weak side than the wooden wheels which were fitted to motor-cars, always taking properly comparable cases. He had never seen a wheel which had been broken in use by impact from the inside, perhaps for the reason that kerbstones did not run down the centre of roads, and that a violent skid could scarcely terminate with the contact of the kerb with the inside of the wheel. Even if it did, the tendency would be for the wheel to lift up and get over the obstacle. He did not condemn wooden wheels; they were beautiful things, and had been developed through the centuries, and he admitted they were much easier to clean than wire wheels. If Mr. Heathcote had not got figures dealing with the weights, he would be very glad to supply them for the information of the Society.

Mr. HEATHCOTE, in reply, said he had not measured the tension on the wheel when running. The diagram he exhibited showing the zig-zags was a hypothetical one. They were simply cosine curves. It was easy to repair a detachable wheel if the spokes broke, much easier than repairing a wooden one. The rider carried one or two spare spokes, which were easily fitted. Roadside repairs were, however, unnecessary if, as was usually the case, the car carried a spare wheel which could be fitted in a few seconds. Where weights had been compared, the advantage was found to be with the wire wheels, and they were also stronger. He did not claim that their wheel was the lightest on the market. With regard to cleaning, the wheels had been designed to stand cleaning with a hose, as the bearings excluded water. He did not see any reason why the load to be sustained should be limited: the case he quoted in which eighty-six people were on a motor omnibus was a very good test. He did not think that lorry or omnibus hubs projected outside the wheel. The rim on heavy vehicles had to be very wide. Some of the wheels for heavy loads were built with double egg-cup hub, with a cylindrical part in the middle, and two cones, one at each end. Some of the spokes went from each side of the hub to both sides of the rim. They had been shown to be adequate for loads far outside ordinary commercial requirements. Motor-car wire wheels were used on vehicles up to 90 horse-power. He was much interested in the Chairman's remarks about locomotive wheels, and in Mr. Beaumont's remarks. As to whether he would attribute the extra life of tyres to the extra resiliency or to the smaller weight, he thought the lengthened life was due to several causes, in which resiliency had a good share, and decrease in weight accounted for very much.

The temperature rise would be less in a wire wheel than in a wooden one. With regard to the case in which the stress was 5,000 lbs., the car in that instance weighed a ton, and Mr. Worby Beaumont mentioned a case in one of his writings which worked out at 7,500 lbs. for the side-thrust under similar conditions. But so great a side-thrust was not likely to arise unless the road was uneven and sloping. With regard to the loss of power due to tyres, he had no figures of his own.

A vote of thanks was accorded the lecturer on the proposition of the Chairman.

HOME INDUSTRIES.

Earnings of Agricultural Labourers.—The fifth of a series of reports relating to the earnings and hours of labour of workpeople in all trades in the United Kingdom is now available. The present report is the third which has been published by the Board of Trade on the wages, earnings, and conditions of employment of agricultural labourers in the United Kingdom, the first having related to the year 1898 and the second to 1902. The average earnings in 1907 of the predominant class of agricultural labourers, when compared with the average earnings in 1898, show a rise of 5 per cent. in England, and of 8 per cent. in Scotland, but as compared with the earnings at the date of the second inquiry (1902) the averages of 1907 show little change. There are considerable differences in the rate of wages, not only in the four countries but in different counties of each country. The average total earnings in the year in England is £47 15*s.*, in Wales £46 16*s.*, in Scotland £50 19*s.*, in Ireland only £29 4*s.* The county in England with the highest average earnings was Durham, with 22*s.* a week, and the lowest Oxfordshire, with 16*s.* 4d. The county in Wales with the highest average earnings was Glamorganshire, with 19*s.* 3*d.*, and the lowest Cardiganshire, with 16*s.* 6*d.* In Scotland, Dumbarton had the highest average (21*s.* 7*d.*), and Caithness the lowest (14*s.* 6*d.*). In Ireland the highest average earnings were 14*s.* a week in Antrim, and the lowest 9*s.* 8*d.* in Roscommon. These earnings are those of adult male farm-servants regularly employed, the earnings of lads, women, and girls having been excluded, and also those of men temporarily engaged at the busy seasons of the year. In comparing these earnings with those of labourers in industrial towns, it must be remembered that the rent of cottages is much lower in country villages than in towns. The village labourer has also better opportunities for growing vegetables, or of obtaining them at low prices, than the urban workman. The holidays allowed without loss of pay to agricultural labourers are few. In England and Wales the only days generally recognised as holidays are Christmas Day and Good Friday, though in most cases occasional extra days are granted. The allowance in Scotland is, in the majority of cases, from two to eight days, five or six being the most usual number. In Ireland there is more variation, no holiday being recognised on some farms, while on others as many as ten days are often observed.

The Hours of Shop Assistants.—There is general agreement that legislation is necessary for the better regulation of shop labour; the difficulty is how to bring it about. Seven years ago an Act was passed which it was hoped would improve the position of the shop assistant, but in fact it has been little better than a dead letter. The hours of shop assistants are much too long—there can be no difference of opinion as to that; and the obvious course would seem to be the compulsory closing of shops. But there are serious difficulties in the way of this drastic procedure, and the Government do not propose to take it. Instead, they limit the working hours of the week to sixty, exclusive of meal times, plus a certain amount of overtime under some system of factory legislation, and Sunday trading is to be rigidly limited to those trades where it is absolutely necessary. The Bill will require a good deal of amendment in Committee, but with the goodwill of the whole House it may be hoped that it will end in an Act which will be of some service to those on whose behalf it has been framed. Experience, however, warns against great confidence as to its working. It often happens that an Act of Parliament is either inoperative or works in a way contrary to the intention of its framers. It is not easy for Parliament to prevent excessive hours of labour in shops when, as will happen in many cases, employers and employed are agreed in desiring to evade the Act. Thus one provision of the present Bill provides that a father and one son may keep their shop open as long as they please, but a second son employed ranks as a shop assistant, and has his hours limited. That differentiation will hardly work in practice. Again, Jewish traders who have observed the Jewish Sabbath are to be permitted to keep open on Sundays to serve only Jewish customers. But how is the Christian who chooses to trade with them to be identified? Some of these puzzles will, no doubt, be solved before the Bill becomes law, and it is probably safe to say that a certain measure of good may be expected from the Act, but the working of the Eight Hours (Mines) Act warrants scepticism as to the realisation of present hopes.

The Cotton Trade with Greater Britain.—The statistical tables recently published relating to British self-governing Dominions, Crown Colonies, Possessions, and Protectorates, give some interesting figures relating to the trade in cotton goods between the United Kingdom and Greater Britain. Out of a total trade valued at £36,671,000, foreign countries supplied only £4,241,000. Last year the increase in the value of Lancashire exports was £12,471,000, and as regards quantity alone £2,981,000,

the average increase in the ten years up to 1909 being £2,400,000. Of cotton waste we send to the colonies nine times as much as foreign countries; of yarn, twist, and thread nearly eight times; of piece goods over twelve times; of miscellaneous goods two and a half times; and of unclassified goods nearly two and a half times. Britain sends to the colonies nearly thirty-nine times as much plain piece goods as foreign countries do, but only seven times as much dyed and printed piece goods. British predominance is greatest in the East Indies, the African possessions (outside South Africa), Australia, New Zealand, and Newfoundland. It is less in South Africa and the West Indies, where the total trade is small, and least of all in Canada, where the United States are such formidable competitors.

Painters' Materials.—The painting trade has to reckon just now with almost unexampled dearness in some of the principal materials it requires. For example, the present price of turpentine is about 74*s.* per cwt., as compared with 26*s.* 6*d.* per cwt. touched in 1909. In 1905 the price reached 63*s.* 6*d.*, but since then there has been nothing approaching the present price. The higher price is mainly due to a falling-off in the output. The principal supplies come from the United States, Russia, and France, but mostly from the United States, which send us at least 75 per cent. of the total imports. Russian turpentine, which is much cheaper than American, is beginning to find more favour with consumers owing to the more scientific methods now being applied to its production. Linseed oil again is quoted at about £47 per ton, which is the highest price touched within living memory. This, too, has been brought about by shortage in the supply. The linseed crops both in the United States and the Argentine—the two chief sources of supply—have partially failed, and the consumption has until recently tended to increase. The original estimates of the surplus of linseed from the Argentine this year were in the neighbourhood of 900,000 tons, but they have gradually shrunk until the generally accepted figure is now not more than 400,000 tons. The United States are the largest consumers of linseed oil, but their own crop of linseed this year is much below the average, and a considerable portion of the supplies of Plate seed which would otherwise come to Europe are being diverted to America. The Indian crop is reported to be very good, but it will not, by a long way, make up for the deficiency in the American crop. Substitutes are being used by consumers, but even here they are hampered by the smaller arrivals of soya beans.

The Milk Bill.—The importance from the national point of view of good milk, and plenty of it, and the admitted deficiencies in the present system by which it is conveyed from the cow to the consumer, make it very desirable that the Milk Bill now before Parliament, for which the Government are responsible, shall become law. Something has been done in recent years to improve the conditions under which milk reaches the public, but we are still far behind many Continental countries in this respect. If the Government Bill is passed, no farmer will be allowed to sell milk until the sanitary arrangements of the farm and the healthiness of the cattle have been certified. Where these are good, a permit will be given for milk to leave the farm. If the public can be persuaded that milk comes from sanitary and veterinary-inspected farms, much of the present distrust should disappear, with the result that the consumption of milk will be largely increased.

Flax Production.—Anxious to maintain the present high prices ruling for flax, Russian cultivators are being advised that their interests will be best served if the area put under cultivation for the new crop does not show an increase of more than 20 per cent. as compared with the old one, the theory being that high flax prices will be maintained if Russian growers do not increase the area under cultivation beyond the percentage named. The need for encouraging the cultivation of flax in all countries where conditions are favourable is being made evident, and the Union of European Flax-Spinners has, during the past year, obtained samples of flax from Japan, Canada, Mexico, and several of the South American States, the retting operations being carried out under proper supervision in Belgium, France, and Holland. The results are said to be very satisfactory, and to indicate clearly that much may be done if cultivators in those countries only receive expert assistance in the best methods of retting and general treatment of the fibre for export. At present three-fourths of the world's supply comes from Russia, but the quality of the fibre is inferior. The extent of flax cultivation in Ireland is still considerable, but the acreage has been gradually diminishing during late years.

Canal Schemes.—The Mid-Scotland Ship Canal National Association have decided in favour of a sea-level canal, 29 miles in length, between Yoker on the Clyde and Grangemouth on the Forth. Other proposals have been favoured in the past. One scheme would have deepened and widened the present Forth-and-Clyde barge canal, either with locks, as at present, or with huge hydraulic lifts at the ends of the present summit level, which is 150 feet above the sea. Another proposal was known as the Loch Lomond scheme. Loch Lomond is only 22 feet above mean sea-level, and was to be connected by a short canal, on the one side with Loch Long, and on the other with the Forth. From the Forth to Loch Long would be 54 miles, and another 15 miles would bring a ship to the Firth of Clyde. Only two locks would have been required, but there would have had to be two very deep cuts at the outlets from Loch Lomond. Alternative cuts from Loch Lomond to the Clyde were also suggested. A strong argument in favour of the Loch Lomond scheme was the possibility of

establishing a shipbuilding and repairing depot on Loch Lomond, well out of the range of an enemy's guns. The direct route now favoured has been proposed before, but as a locked canal with twelve locks and a maximum height above sea-level of about 90 feet.

English and American Yarns.—Why is it that English cotton-spinners can make a more even yarn than their American competitors? The Americans have as good machinery as the English; in some of the American mills the machinery is the same make—then why the inferiority? The question is put by the *Textile World Record*, which gives as the answer the quality of the labour employed. American spinners "do not, or cannot, get the 'help' to give the same attention to the details of the work that they do in England." Putting aside Lancashire's climatic advantage, which might perhaps be overcome by artificial means, the writer gives a list of details, neglect of which by American operators is said to be the cause of inferiority in yarn. But this only means vigilant management, and management is highly specialised in the United States. Perhaps the explanation is to be found, at any rate in part, in the fact that in America the keynote of the trade is production, whereas in English mills, though output is vital, there is less readiness to make some sacrifice of quality to ensure it.

CORRESPONDENCE.

ART EDUCATION IN THE JEWELRY, GOLDSMITHING, AND ALLIED TRADES.

In the discussion following Mr. George Heming's paper, Mr. Henry Wilson, in reply to Dr. Garnett's question as to how far machinery might be applied to artistic crafts, argued that not only could the spinning of metal be legitimately used in the silver trade, but that "spinning artists" might be encouraged!

The meeting was held to discuss art education in the jewelry, goldsmithing, and allied trades, and at the commencement of his remarks Mr. Heming said, "the demon of the machine pulled us down." Now the spinning-lathe is one of the claws of this disintegrating monster. It was, in conjunction with the decay of the apprenticeship system, one of the main reasons for the establishment of technical classes; it was one of the reasons why a critic called silversmithing "the most degraded of all British arts," and it is one of the causes for the lavish display of cheap and showy goods in the windows of pill vendors and fancy goods bazaars.

The spinner cannot be an artist. He is a mechanic rubbing metal into a chuck, which is generally provided for him. He can no more be considered analogous to the potter than the metal-stamper to the smith.

Besides the sentiment which attaches to wrought work, there is substance and durability. It is impossible that the antique silver, which is now so much prized, would have survived had the metal been spun upon the lathe. It was fashioned by consummate craftsmen, whose subtle fingers had indeed demonstrated that veritably "by hammer and hand all arts doe stand." Mr. Wilson said: "It was the man behind the machine who always had to be considered." Alas! there is much more in that than appears on the surface. It is the one man on whom all others are to be dependent; upon whom they are to rely for their daily bread, which they may earn by mechanically and monotonously producing replicas of his work. Shall we develop the divinity of man in this way; shall we make the daily work "more than a mere struggle for our daily bread"? Brought into daily touch with the trade as editor of a trade journal, and with the young as technical instructor, I see too much of the demoralising effects of strictly commercial production and the domination of the many by the man behind the—I was going to write Maxim gun—machine.

Every object made by means of the stake and raising hammer has behind it the most subtle of all machines imposing his individuality, and frequently consummate insight and ability, upon the object he is fashioning. On the other hand, the spinner is a conscious machine, merely pressing his material on to a pattern, and, like the stamper, automatically producing another's design upon another's model.

Mr. Wilson cannot realise how craftsmen—both masters and men—who have been injured and disheartened by this machine, have suffered, and how hopeless it seems to those of us who are anxious for the good of our craft, when we hear our champion as apologist for that curse of the modern smith—the spinning lathe.

W. AUGUSTUS STEWARD.

Central School of Arts
and Crafts, W.C.

My wife and I were both greatly saddened at the paper on the above subject, and much of the subsequent discussion, wondering why, after sixty years, this educational ploughing of the sands should so hopelessly go on. Mr. Heming must indeed be an optimist if he is not really blind to the fact that he and his fellow-enthusiasts are on entirely wrong lines, and are going in an exactly opposite direction to that which they desire. Surely the great art work of the world has not been effected by the wholesale manufacture of designers. The very traditions cited by Sir George Birdwood—who probably knows more about the arts of the ancient world than anyone present—referred rather to the patient continuance in well-doing of the craftsman, than any consideration of an emulative designer. Since 1851 we have gone on, more or less, trying to create designers in this

country. What has been the result? Have we not, in ninety-nine cases out of a hundred, spoilt a probably good craftsman by making him a discontented, because uninspired, artist? The lecturer and his friends would continue this process, with the logical and inevitable consequence, to the workshop, of it being occupied by a number of people, not so much interested in that patient continuance in their craft I have alluded to, as in the suppression of their own immature ideas. The speaker in the discussion who asked us to educate our shopmen, who showed the pretty things over the counter without the power to describe them adequately, set the true seal, not only upon this paper, but upon our whole system of educational training. For the intelligent prosecution of a craft the only art training necessary is the practical geometry and elementary free-hand drawing, of which every boy should know something. If he has the ambition and feels within him the divine afflatus of design, he can get the necessary training and art education—he will get it—and that without any forcing.

I will only touch on the machinery question—it need not have been dragged in. Any machine is obviously only a workman's tool—even the Syracusan coin owes something to a machine.

PHILIP H. NEWMAN.

39, Brunswick-square, W.C.

OBITUARY.

SIR CASPAR PURDON CLARKE, C.V.O., C.I.E., LL.D.—Sir Caspar Purdon Clarke died on the 29th of March, after a long illness. He became a member of the Society in 1884, and read papers before the Society on "The Domestic Architecture of India," "Street Architecture in India," "Modern Indian Art," and "English Brocades and Figured Silks," for two of which he received the Society's silver medal. He also took part on numerous occasions in the discussions, and often contributed to the *Journal*.

He was born in 1846, and was a student in the National Art Training School, where he won medals. He was originally educated as an architect, and in 1867 he was engaged in the architect's office of the South Kensington Museum. An early piece of work, which obtained him much credit, was his building for the Legation at Teheran in 1874. One of the first things which brought him into public notice was his arrangement of King Edward VII.'s Indian presents in the galleries afterwards devoted to the Indian Museum at South Kensington, and for his services on this occasion he was awarded the C.I.E. in 1882. After this he was employed on various commissions for acquiring art objects for the South Kensington Museum in Greece, Turkey, Syria, and India. The most important of these expeditions was perhaps the one he carried out for the Indian and Colonial Exhibition of 1886. In 1883 he was appointed Keeper of the Indian Collections. Nine years later he was advanced to the post of Keeper of the Art Collections of the South Kensington Museum. In 1893 he became Assistant Director of the Museum, and, after the death of Sir Philip Cunliffe-Owen, was appointed Director in 1896. This post he held until 1905, when he resigned, and was appointed Director of the Metropolitan Museum of Art in New York. After holding this post for some five years, he resigned it and returned to England.

In addition to his official work in connection with the Science and Art Department, he did a great deal in connection with various exhibitions, especially those of which the British Section was under the superintendence of Sir Philip Cunliffe-Owen. He also built the Indian Palace for the Paris Exhibition in 1889, and it was under his superintendence that the elaborate Indian buildings, which formed an important part of the Indian and Colonial Exhibition, were constructed. He was knighted in 1902, and obtained the C.V.O. in 1905.

NOTES ON BOOKS.

SIX GREEK SCULPTORS. By Ernest A. Gardner, M.A. MEDIAEVAL ART. By W. R. Lethaby. WILLIAM BLAKE. By Basil de Selincourt. London: Duckworth & Co. 5s. net a volume.

The series of volumes constituting Messrs. Duckworth & Co.'s "Library of Art" has proved so successful that it has been decided to reissue them in a cheaper form. The new edition will doubtless be warmly welcomed by many students of art who found the price of the first issue more than they could afford. The series has already taken its place as a standard library of art criticism. The contributors have in each case been carefully selected, and the list includes only those who can speak with authority on the subjects with which they deal.

No one is better fitted, both by training and instinct, to deal with Greek sculpture than Professor Ernest Gardner. A classical scholar of the first rank, he was for eight years Director of the British School at Athens; he was also engaged in excavation in Egypt, Cyprus, and many sites in Greece, and has written much on various branches of Greek art and archaeology. In the present volume, the six sculptors, Myron, Phidias, Polyclitus, Praxiteles, Scopas, and Lysippus, are selected; their work is described and criticised in a singularly appreciative and sympathetic style, and the influence of the earlier artists upon their successors is carefully explained.

In dealing with mediaeval art, Professor Lethaby has a very wide field to cover. Starting with the age of Constantine, he proceeds to describe later Byzantine origins, Romanesque art in Italy, Germany,

France, and England, Gothic characteristics, French cathedrals, sculpture, and painting, and so on through Gothic art in England, Spain, Switzerland, Belgium, and Germany, to his concluding chapter on Gothic art in Italy. With a subject extending over ten centuries and the greater part of Europe, it goes without saying that a volume of this size does not afford scope for anything like exhaustive treatment. With this limitation, however, Professor Lethaby's account is admirable, and well calculated to stimulate the student to further study, which is perhaps as great a compliment as one can pay to a book of this description. A word, too, should be said in praise of the well-chosen illustrations, some of which are very striking, notably the West front of Strasbourg Cathedral, the West door of Sens Cathedral, the door of the North transept of Reims Cathedral, and the choir of Rouen Cathedral. The student who has assimilated these, and Professor Lethaby's account of them, will begin to have a good idea of what is meant by mediaeval art.

It is difficult to write with sanity and moderation about the visionary, William Blake. His admirers see in his work so much more than meets the ear or eye; his detractors regard him as little better than a lunatic. Mr. Selincourt appears to have hit the happy mean. While appreciating Blake's lofty ideals and fine enthusiasm, he is by no means blind to his faults as man and painter, and he has consequently written a discriminating book, giving perhaps the best account of Blake that has yet appeared. Whatever one may think of Blake's poetry, or his art, or his theories about art, one can hardly deny that he was a most remarkable character, and one that, for its human interest alone, will repay a little study.

Notes on Practical Cotton Finishing. By J. Harold Edge, F.C.S. London: The Trades Papers Publishing Co., Ltd. 3*s*. 6*d*.

The nature and scope of this little volume are accurately described by its title. Mr. Edge passes from a very short account of the history of cotton finishing to a brief note on the various kinds of cotton fibre; he then proceeds to deal with water in the finishing works, softeners, and conditioners, starches and fillings, antiseptics, blues, etc., and concludes with a useful and fully illustrated chapter on finishing machinery. The subject is dealt with from an eminently practical point of view, and is written in language that should be intelligible to the master and foreman finisher. The tests given for trying the purity of the water, and the materials used in finishing, have been prepared so as to enable those engaged in finishing work, who have not been trained in chemistry, to apply technical and scientific tests with reagents they can understand, and to obtain results they can follow. Mr. Edge writes with considerable authority, for he has had opportunities of studying finishing work in America as well as in Europe.

GENERAL NOTES.

The Corrosion of Metals.—The Corrosion Research Committee of the Institute of Metals is now actively engaged in preparing for an elaborate series of investigations into the causes of the corrosion of brass condenser tubes. A special condenser is being constructed, which will contain forty-eight tubes, twenty-four of these being made of commercially pure brass, and the remaining twenty-four tubes of brass containing a single selection from lead, tin, aluminium, manganese, or other material at the discretion of the committee. Experiments will be made with various water speeds in the ratio of 0 : 1 : 2 : 3 : 4, speed 2 being an average speed used in practice. The circulating water to be used will be obtained from deep water at Formby, off Liverpool, in the first instance, and the plant for the corrosion research will be installed in the University of Liverpool, where the experiments will be under the direct supervision of Mr. G. D. Bengough, M.A. It is expected by the committee that the research will prove to be one that will occupy many months before any definite conclusions can be reached, and it will undoubtedly be costly. Though the total amount received (£242 5*s*. 6*d*) is sufficient to enable the work to be commenced, the cost of the research must ultimately be very much greater than this. If the research is to be properly carried on, the expenses will probably amount to not less than £300 per annum. Donations should be sent to Mr. G. Shaw Scott, M.Sc., the Secretary of the Institute of Metals, at Caxton House, Westminster, S.W.

Patents in 1910.—The report of the Comptroller-General of Patents, Designs, and Trade Marks, for the year 1910, has been issued as a Parliamentary paper. During the year there were 30,388 applications for patents; of these 20,768 were provisional, 19,105 were complete, and 16,269 were sealed. The corresponding figures for 1909 were 30,603, 21,553, 18,705, and 15,065. The applications received from women inventors numbered 671, as compared with 648 in 1909. There were 1,482 applications made by way of communication from abroad, of which 728 came from the United States, 431 from Germany, 53 from Italy, 33 from India, 25 from Switzerland, and 21 from Austria. The number of applications made in this country under the provisions of the International Convention for the Protection of Industrial Property by the various States of the Union in 1910 was 2,829, an increase of 526 as compared with 1909. The number of designs applied for during the year was 30,872, excluding 1,873 sets of designs, as compared with 24,816 single designs, and 1,596 sets in 1909. The number of designs registration of which was refused was 591. Applications were made for the registration of 10,623 trade marks as compared with 10,880 in 1909. The number registered was 5,722, as against 6,112 in 1909.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

APRIL 26.—NOEL HEATON, B.Sc., F.C.S., "The Production and Identification of Artificial Gems."

MAY 3.—A. W. GATTIE, "London Transport."

MAY 10.—HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

MAY 17.—Professor RAOUL PICTET, "Les Basses Températures."

MAY 24.—FRANK M. ANDREWS, "Architecture in America." Sir ASTON WEBB, C.B., R.A., F.R.I.B.A., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock :—

APRIL 27.—Sir THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Lord AVEBURY, D.C.L., LL.D., F.R.S., will preside.

MAY 25.—W. R. H. MERK, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock :—

MAY 9.—F. WILLIAMS TAYLOR, "Canada and Canadian Banking."

CANTOR LECTURES.

Monday Evenings, at 8 o'clock :—

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal : its Structure and Uses." Four Lectures.

Syllabus.

LECTURE I.—MAY 1.—*The External Form of Rock Crystal and Chemical Character of its Substance.* Early Observations of its Geometrical Shape, and Conclusions drawn therefrom as to the Nature of Crystals in General—The Modern Conception of a Crystal—Measurement of the Angles between the Faces of a Quartz Crystal, and the Facts thereby Deduced—The Plan or Scheme of Arrangement of the Faces, and the Occurrence of Right and Left-handed Varieties of Quartz.

LECTURE II.—MAY 8.—*The Internal Structure of Rock Crystal, and the Means we possess of Elucidating it.* The Chemical Molecules of Silica, and their Arrangement in a Space-lattice — The Influence of the Arrangement of the Elementary Atoms in the Molecule of Silica in Determining a Right or Left-handed Screw Structure—The probable Disposition of the Atoms and Molecules in the Right and Left Varieties of Quartz, and the Effect of this Internal Structure in determining the Outward Geometric Form—Revelation of the Oppositely Helical Structure by Etching and Liquid Cavities.

LECTURE III.—MAY 15.—*Optical Evidence of the Two Complementarily Opposite (Mirror-image) Screw Structures.* Rotation of the Plane of Vibration of Polarized Light in Contrary Directions by the Two Varieties of Quartz—Experiments on the Artificial Reproduction of the Quartz Phenomena, in proof of the suggested Screw Structure—The Twinning of Quartz and Apparent Enhancement of the Symmetry and Destruction or Modification of the Optical Activity thereby—The Interesting Case of Amethyst—The Magnificent Polarization Phenomena of Twinned Quartz.

LECTURE IV.—MAY 22.—*Scientific and Industrial Uses of Rock Crystal.* Its Thermal and Electric Properties, and its Transparency to Ultra-violet Rays—The Construction of Prisms and Lenses (including spectacles) of Rock Crystal, and their Advantages over Glass—The Use of Quartz for Balance Weights and in connection with the Interferometer—The Artistic Use of Quartz for the Carving of Vases and other Objects—Destruction of the Crystalline Structure by Fusion, and the Uses of Fused Silica in Fibres and Scientific Apparatus.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 10...Institute of Brewing (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. B. T. P. Barker, "The Principles and Practice of Cider Making."

Optical, at the Chemical Society's Rooms, Burlington House, Piccadilly, W., 8 p.m. Mr. H. S. Ryland, "The Forms and Errors of Visual Lenses."

Geographical, Burlington-gardens, W., 8.30 p.m. Mr. Douglas Mawson, "On the Plans of the Australian Antarctic Expedition, 1911-1912."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. R. Anning Bell, "Coloured Relief as Decoration."

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. K. Vyasa Rao, "A Statutory Royal Viceroy for India."

TUESDAY, APRIL 11...Asiatic, 22, Albemarle-street, W., 4 p.m. Sir J. George Scott, "The Religions of the Shan States."

Engineers, Junior Institute of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Major B. Baden-Powell, "Recent Progress in Aeronautics."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. J. W. Smith's paper, "The Improvement of Highways to Meet Modern Conditions of Traffic," and on Mr. H. P. Maybury's paper, "Recent Development in Road-Traffic, Road-Construction and Maintenance."

Photographic, 35, Russell-square, W.C., 8 p.m. Messrs. C. E. Kenneth Mees and C. Welborne Piper, "On the Fogging Powers of Developers. Part I. General Introduction. The Hydroquinone Developer."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Mr. C. W. Boyd, "The Development of Rhodesia."

WEDNESDAY, APRIL 12...Automobile Engineers, at the Institution of Mechanical Engineers, Storey's-gate S.W., 8 p.m. Mr. A. Mallock, "The Effects of Wheels on Roads."

Japan Society, 20, Hanover-square, W., 8.30 p.m. Mr. E. F. Strange, "The Art of Kyōsai."

Journal of the Royal Society of Arts.

No. 3,04 . VOL. LIX.

FRIDAY, APRIL 14, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

CONVERSAZIONE.

The Society's Conversazione will be held this year at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday, May 30th, from 9 p.m. to 12.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A Meeting of the Colonial Section was held on Tuesday, April 4th, 1911, the Right Hon. Lord DENMAN, K.C.V.O., Governor - General Designate of Australia, in the chair.

The CHAIRMAN said he considered it a great honour to have been asked by his noble friend, Lord Blyth, to take the chair that afternoon on such an interesting occasion. He gathered that the paper was one of a series delivered under the auspices of the Society concerning each of the over-sea dominions. He thought, particularly this year, when so many fellow-subjects from across the seas were visiting this country to attend the Coronation ceremonies, it was obviously desirable that every opportunity should be taken of gaining an increased knowledge of those dominions. He himself hoped to do so that afternoon, for he stood perhaps more in need of such knowledge than any other man in the room. There was just one point which he should like to mention. No one at all conversant with Australian affairs could fail to notice how many sailors had given their services to that country. He would mention, as examples, the late Sir Harry Rawson, the popular Governor of New South Wales; Admiral Sir Frederick Bedford, for some years Governor of Western Australia; Admiral Sir Day Hort Bosanquet, who at the present time was the Governor of South Australia; and lastly, Captain Collins, who for many years was in the Royal Naval Service. Captain Collins had been intimately associated for many years with the naval defence of Australia. He had been Secretary of the Department of the Defence of the Australian Commonwealth for four years; he had been the representative of the Commonwealth Government in this country, and during that time not the least of the services he performed was the establishment of the office of the High Commissioner of the Commonwealth in London. It would be very easy for him (Lord Denman) to say a good deal more concerning the services which Captain Collins had rendered to Australia, but he thought he had said enough to show how well qualified he was to address the members of the Society, and he was sure he would be able to rely upon an attentive and appreciative audience.

The paper read was—

THE COMMONWEALTH OF AUSTRALIA.

By CAPTAIN R. MUIRHEAD COLLINS, R.N., C.M.G.,

Official Secretary in Great Britain for the Commonwealth of Australia.

To endeavour to speak comprehensively and clearly of any young country within the short space of a paper is a formidable undertaking, but it is much more formidable when that country is a continent in itself. If you would in a moment comprehend something of the wide range of Australia's climate, soil, production, and scenery, you cannot do better than run your mind over all the various climates, soils, products, and scenery which you know exist in Europe. For Australia is just as various in all these things as is Europe, with tropical regions added. In her great stretch from north to south she embraces lands to which the inhabitant of any country on the Continent of Europe might be transplanted with any of his industries without suffering hardship or even change. In Australia we could find districts into which each and every European engaged in primary production could be made to feel at home.

As has been pointed out by Mr. Knibbs, the Commonwealth statistician, Australia, by reason of its insular geographical position and the absence of striking physical features, is far less subject to extremes of weather than are regions

of similar area in other parts of the globe, and, latitude for latitude, Australia is far more temperate.

The range of summer and winter temperatures in Australia, as in other countries, increases with increasing distance from the coast, but even in the interior, where the heat is greatest, the nights are cool, and the extreme dryness of the air renders the heat easily bearable and very healthy.

Such is the magnificent climate; but there lurks in the minds of many people the association of droughts with Australia, and the idea that we have a country with a fringe suitable to settlement and a huge interior desert. It is necessary to correct this impression. Droughts we have had, and droughts we shall have. It has taken the colonists some time to learn the lesson of drought, and to realise that it can be fought. With increasing knowledge, with improved methods of farming, with irrigation, the evil effects of drought steadily diminish. So it is with land classed as desert. It may be said, as science advances, the desert recedes.

The possibilities, however, of Australia, as regards rainfall and production, can at once be realised by a consideration of the following facts:—For some time land with an annual rainfall in excess of 18 inches, provided the soil is of good quality, has been considered suitable for closer or farming settlements. Well, it is computed that Australia has no less than 529,000,000 acres of this. Now, when you consider that the total area of France, with 40,000,000 people, is not quite 133,000,000 acres, and the total area of Germany, with 60,000,000 people, is not quite 136,000,000 acres, and the total area of Spain, with 20,000,000 people, is not quite 126,000,000 acres, you can have some idea of the vast area of land available for production in Australia, and conceive how it must be destined as a home for a great people. But we can evidently go further than this margin of rainfall. Recently a conference, convened by the Minister of Agriculture in South Australia, was held at Adelaide to consider the question of dry-farming. Expert officials from all parts of the Commonwealth attended. It was pointed out that many millions of acres of agricultural land, of which the rainfall varied from 10 to 16 inches per annum, were awaiting development. The Minister of Agriculture said that South Australia alone had 30,000,000 acres, and that last season 55 per cent. of the wheat produced in that State came from land having less than 16 inches rainfall. It can be seen from this what a revolution is being effected by dry-farming.

Australia is a land unrivalled in the production of wool. It is interesting to recall the fact that a Governor, in the early days of settlement, reported that the country was not suitable for sheep. Australian pastoralists have made increasing efforts towards the development of their flocks. When pure merino rams were first introduced into Australia from Spain, they averaged about 3½ lbs. of wool. To-day the stud merino ram yields over 40 lbs., and the average for the million of flock sheep is nearly 8 lbs. at each shearing.

Our mineral resources are only partially developed or explored, yet the total value of mineral production for 1909 was over £23,000,000, and the total yield of gold since 1851 is over £525,000,000. The deposits of coal and iron are enormous.

As a wheat producer, we are but in our infancy. The production of wheat for last year was 89,735,000 bushels, of which 28,943,000 centals, valued at £9,922,000, was exported. It is stated that the area at present under wheat represents probably one-twentieth of the lands of Australia fitted to produce crops under existing conditions of cultivation, and probably only one-fortieth of the area on which wheat could be grown under scientific methods of dry-farming.

So much for the climate and resources. Our possibilities have so much impressed one of the Scottish Agricultural Commissioners, who have recently returned from a visit to Australia, that he said it appeared to him that Australians did not sufficiently appreciate them. We are not supposed generally to be a modest people, but here is testimony to the contrary.

What is being done to make Australia attractive and profitable to the settler, whether he be native-born or a new arrival from the Mother Country, can only be sketched in outline in a general paper of this kind. The first phase in our land settlement was pastoral settlement. Then came the farming settlement on areas which, although small from the early grazing point of view, were extraordinarily large when compared with the average size of farms in other countries.

We are at this moment embarking upon the third stage, which means the intensive cultivation of areas much smaller than those held by our farmers up to the present time.

I shall mention as an illustration what is on offer by the Western Australian Government. The land-seeker there can acquire an area of good farming land up to 1,000 acres in extent for a

deposit of 3*d.* an acre. He will pay from 15*s.* to 25*s.* for excellent wheat-growing country, and be allowed twenty years in which to pay for it. In addition to that the Government Agricultural Bank will advance him up to £400 without any security but the land upon which he has paid 3*d.* an acre. This £400 is to be spent upon horses and implements, and fencing and clearing, and other improvements, and is paid to the settler as he makes his purchases or carries out his work. This means that an approved man, with practically no capital at all, can become the possessor of a farm which will give him a very substantial income indeed. The Hon. James Mitchell, Minister for Lands in Western Australia, declared the other day that 80 per cent. of the settlers in recent years had less than £50 of their own at the time of entry.

When you consider that Western Australia is now carrying farmers and farm-labourers from the Mother Country to the State at £2 a head, which means that the Government is paying £10 towards each immigrant's fare, and that there is a great demand there for farm-labourers, and that wages are high, you will see how easy it is for a young man in one of the rural districts in Great Britain to become a farmer in Western Australia.

Australia is sometimes charged with being indifferent on the question of immigration, but I think that this example of what this one State is doing to make its empty spaces available for the young Britisher should convince the world that we are deeply in earnest in the peopling of our country. And what is true of Western Australia is more or less true of the majority of the States. Most of the States provide cheap steamship fares, and all of them offer plenty of work at good wages. Then a wide choice of lands available, as I have shown, on remarkably easy terms, makes the way very easy for the man who enters Australia with the capacity and determination to succeed as a settler on the land.

We have still a long way to go in Australia before we shall have disposed of all the well-watered country suitable for dense farming settlement. The good rainfall area is in itself capable of carrying a very big population. But that is only the beginning of our opportunities for settlement. We have, in addition, splendid areas of land available for irrigation. It is often said that Australia's rivers are relatively insignificant, but still it has been unmistakably shown that if their waters are properly conserved and distributed over the soil, instead of being allowed to run to the sea, they will become a most important factor in our national wealth.

The purpose of irrigation will be the increase of the output on the lands already settled, and the indefinite expansion inland of the areas suitable for farming. A remarkable feature of the inland country is its sweetness. Hundreds of miles from the coast, where the rainfall is scanty and the good seasons intermittent, the soil is in the good years thickly coated with a great crop of natural grasses and herbage which are nutritious right down to the ground. This ample territory of light rainfall is always ready with its prolific response to moisture. Give it water, and it will grow almost anything.

Round some of the artesian bores of the interior one finds beautiful oases of native grasses and edible shrubs, of lucerne, cereals, and many varieties of fruits. There is the combination of sunshine and rich land reaching out almost interminably over a surface undulating very slightly, if not quite level. Add to this water, and you turn thousands of square miles into a garden.

The recognition of these facts has already led to some irrigation enterprises of considerable magnitude. And in irrigation, as in so many other fields, you find the State playing an important part. American irrigation is largely the result of private enterprise, which has gained perpetual rights over the most important irrigation waters. In Australia the State has decided to give no freehold rights over its running streams. In the big works now in hand the Government constructs the head and other conservation works, and also the main channels of distribution, and sells the water to the landholders at cost price, plus working expenses. This means that water for irrigation purposes in Australia is, in the opinion of experts, the cheapest in the world. Generally speaking, too, the State purchases large areas of the land about to be watered, and disposes of this under easy conditions to the settlers.

In the State of Victoria, which, although by no means the least favoured by rainfall, has pioneered irrigation in Australia, we find that already £3,500,000 have been spent on the construction of irrigation works during the last twenty-five years, commanding for irrigation over 1,000,000 acres, and giving a stock and domestic water-supply of over 6,000,000 acres.

In order to obtain settlers for these areas, the Government in 1910 despatched a delegation to Great Britain and America, the purpose of which was to secure desirable settlers for the Victorian

irrigated areas. The delegation's efforts resulted in remarkable success; already from Great Britain alone 1,300 people with their families have applied for irrigation blocks in Victoria, representing a total capital of £230,000. The State Government estimates that during the next twelve months all the available land commanded by the present water storage will be taken up, and is, therefore, undertaking further storage works, and in the near future additional large tracts of irrigable country will be offered to settlers.

It is not astonishing that this irrigated country in Victoria has been rushed by settlers from both the Mother Country and America. The scheme is aimed at people who possess a little capital, and the State assists to a remarkable extent. For instance, take the case of a man who goes out from England. He is loaned four-fifths of his steamship fare. When he lands in Melbourne, he is offered good board and lodgings at a special State lodging-house for the sum of 2*s*. 6*d*. per day. He gets special concessions over the State railway lines, and is given the fullest opportunity of seeing all that is on offer. We will assume that he buys a block of sixty acres. His farm will not be in its primitive forest state, but will be country which has been under ordinary unirrigated cultivation for many years. The State will build him a house and give him several years in which to repay the money, and also assist on the same basis in the buying of live-stock and implements and the effecting of improvements.

There is no rough pioneering, no isolation about this new phase in our settlement. The irrigable land is all situated close to old-established railways and prosperous country towns marked by pleasant social life. The channel of pure river water which flows through or past each settler's block means that very soon he will have a beautiful as well as a prosperous home.

It is anticipated that the present rush of settlers will speedily exhaust the irrigated land available in Victoria, and so it is good to be able to say that an even bigger scheme is approaching maturity on the other side of the Murray, in New South Wales. In this State a great dam, with a capacity for conserving water eleven-twelfths as much as that conserved by the famous Assuan Dam across the Nile, is being constructed across the Murrumbidgee River at Barrenjack.

Then South Australia is also initiating works on a big scale. And one is safe in saying that for many years ahead we shall be duplicating these schemes and making large areas of land available for the stranger from oversea.

As an illustration of what is proceeding in Australia under the policy of repurchase of land and closer settlement, the Surveyor-General of South Australia reports as regards his State:—"In order to prove that the subdivision of large estates has been most successful it is only necessary to record that prior to repurchase by the Crown the population, so far as can be ascertained, on 465,208 acres of freehold land was only 387, and there were also 269,700 sheep, 1,828 cattle, and 709 horses. To-day, on the same land, there is a population of 4,313 (including 2,002 children), and in addition the stock comprises 111,099 sheep, 7,073 cattle, and 6,217 horses; 73,860 acres were under cultivation last year for cereals and hay, and there were 1,721 acres of gardens and orchards, while 928,242 bushels of wheat and oats and 16,150 tons of hay were taken off last harvest."

The position to-day is that we in Australia have the surplus lands, and that you in the Mother Country have the people who can settle those lands, and thereby add to the wealth and the strength of Australia, and at the same time add to the wealth and the strength of the Empire as a whole. Every additional acre we settle, every additional ton of produce we win from the soil, means more strength, and, if need be, more fighting strength, to the British people.

Before I pass on to another subject, I would like to refer to the subterraneous waters which form a remarkable and interesting feature in connection with the development of Australia. There is an artesian area of over 640,000 square miles. Large supplies of water have been tapped, but it is found that artesian waters in some cases are charged with alkali which is inimical to fertility. The attention of Mr. Symmonds, a chemist in Sydney, was drawn to this, and he applied himself to the investigation of a means of neutralising the injurious effect of the alkali on growth. He found that soil from these districts, when treated with rain-water, was highly fertile, but treated with artesian water it became acid and caked. He then tried the effect of nitric acid applied to the bore-water, and this gave surprising results. The soil became richer even than when treated with rain-water. Here was an interesting discovery; but then came the question how to give it a wide application and commercial value. Mr. Symmonds proposed to adopt the method which is in certain cases now applied to the manufacture of cordite, and get his nitrate from the atmosphere. But this

might be an expensive process, so he proposed to use the power of the bore-water itself to carry out the work of extracting the nitrate.

His investigations, however, have carried him further, to find that in the shallow bores the water was strongly charged with carbonate of soda, which is death to plant life, but that at greater depths the soda elements decreased, and the water was rich with fertilisers.

Concerning such investigations, Mr. Hunt, the Government Meteorologist, has written to me:—"I have been endeavouring to collect data relative to the results of tests made to discover a means of neutralising the effects of bore-water on adjacent lands. Senator Millen has taken a good deal of interest in the question, and, in response to inquiries as to his experience in the use of artesian water, I have received from him a letter, of which the following is a copy:—

"'Regarding the tests to which you refer, though no doubt interesting from a scientific point of view, they failed to suggest anything of commercial value. But even had they resulted otherwise, I doubt if the present use of the water would have been disturbed. Its value to-day for grazing is greater than its problematical value for irrigation. An artesian well will water 50,000 acres for stock purposes, whereas it would probably not irrigate more than 150 to 200 acres. The Department tacitly accepts this view, for it makes no pretence of putting down wells for any other than stock purposes. Bear in mind that there is a limit to the number of wells that can be put down with safety.

"'With regard to the "caking" tendency where irrigation is practised with artesian water, the same thing is observed in certain localities even where river water is used. I do not think the caking—by itself—would be fatal. It is the corrosive action of the soda, with which practically all our artesian waters are charged, that represents the real evil.

"'My own experience is still too brief to warrant the expression of definite opinions. Further, the water varies in every bore.'"

This is a subject that is very interesting, and of which no doubt we may expect to hear further, as closer settlement advances on those artesian areas now almost entirely pastoral.

I will now turn for a few minutes to the Australian Constitution and politics. The Federation, as you are doubtless aware, consists of six States, and differs from that of Canada, or that of the more recent South African Union, in that the powers of the Federal Government are more restricted. We still have six State Parliaments, each consisting of two Houses, of which the Legislative Councils of New South Wales and Queensland are nominated. With the exception of the Upper Houses in New South Wales, Victoria, and Queensland, members are paid. As Lord Rosebery remarked: "A land which will support so many legislators must be a land of exceeding great prosperity."

The legislative power of the Commonwealth is vested in the Federal Parliament, consisting of the Sovereign, the Senate, and the House of Representatives. There are six senators for each State, chosen by the people of the State voting as one electorate, and they are elected for a term of six years.

Half the senators for each State vacate their seats at the expiration of three years in the case of the election of a new Senate. One-third of the whole number of senators must be present to constitute a *quorum*.

The House of Representatives consists at present of seventy-five members. The Constitution provides that they shall be as nearly as possible twice the number of senators. It is elected for three years. The number of representatives to be elected is arrived at in the following manner: A quota is obtained by dividing the total population of the Commonwealth by twice the number of senators—*i.e.*, by the number seventy-two. Then the number of representatives for each State is got by dividing the population of the State by the quota. If there is any remainder from the division greater than half the quota, one more member is allotted to the State.

At the time of the establishment of the Constitution, provision was made for the payment to members of both Houses of a salary of £400 per annum. This has since been increased to £600 per annum. Both Houses are elected on adult suffrage, every man and every woman of twenty-one years of age being entitled to vote, and every vote is of equal value.

It is interesting to note the proportion of women voting to that of men. At the General Election, 1910, the percentage of electors voting to electors enrolled was, in the case of men, 67·58 per cent., and in the case of women, 56·17 per cent., and for the House of Representatives, 68·12 per cent. for men, and 56·93 per cent. for women.

Under Federal law voting by post is allowed, under the following conditions:—

An elector can vote by post: (*a*) Who on polling day will not be during the hours of polling within five miles of any polling place for his division; (*b*) Or, being a woman, will, on account of ill-health, be unable to attend; (*c*) Or if the elector will be prevented by serious illness.

Application has to be made for a postal vote certificate and postal ballot paper. The paper must be witnessed by a J.P., electoral registrar, medical man, or other person designated as qualified to witness.

The Commonwealth Government has taken over those affairs which may be roughly termed national. It controls external affairs, defence, Customs, post, telegraph, and telephone services, quarantine and shipping, and landing of persons in Australia. These are some of its functions, but it has powers not yet exercised; for instance, it is authorised under the Constitution to take over the control of the railways.

The chief functions of the State Governments may be said now to be the settlement of lands, the encouragement of mining and agriculture, and the control of education and State public works.

Since the establishment of the Constitution, the Federal Government has enlarged its powers by the means provided—namely, referendum. A referendum was taken in April, 1910, by which the Commonwealth obtained power to take over the whole of the State debts. Before this amendment the Commonwealth had only the power to take over the debts as existing at the time of Federation. At the time of this referendum 31 per cent. of enrolled electors voted in favour and 25 per cent. against. There were 29,249 votes by post.

We have lately had in England our attention drawn to the referendum. The referendum in Australia is embodied in the Constitution, but not as a means of settling any disputes between the two Houses, although there is provided a double dissolution of the Senate and the House of Representatives in the case of disagreement. Since Federation there have been three referenda taken. The first one, in February, 1907, dealt with the term of service of senators. This was carried. On April 13th, 1910, two questions were submitted to the vote. One was the taking over of the State debts, to which I have already referred, and which was carried, and the second was a financial agreement between the Commonwealth and the States, enacting a payment of 25*s.* per head of the population to the States from the Commonwealth revenue, in lieu of the clause of the Constitution known as the Braddon Clause, which provided that during a period of ten years after the establishment of the Commonwealth, the Commonwealth was annually to apply only one quarter of the net revenue obtained from duties of Customs and Excise to its expenditure. The balance—namely, three-fourths of the net revenue—had to be paid to the several States, or applied towards payment of interest on the debts of the several States taken over by the Commonwealth.

This proposed alteration was lost, the majority voting against it. But, since that, the present Commonwealth Government has passed an Act settling the financial relations between the Commonwealth and the several States, in view of the period provided for under the Braddon Clause having expired.

This Act provides that during a period of ten years, beginning on the first day of July, 1910, and thereafter until Parliament otherwise provides, the Commonwealth will pay to each State by monthly instalments, or apply to the payment of interest on debts of the State taken over by the Commonwealth, an annual sum amounting to 25*s.* per head of the number of people of the State. Provision is made for the special payment to the State of Western Australia of an annual sum, which in the first year shall be £250,000, and in each subsequent year shall be progressively diminished by the sum of £10,000. The Commonwealth Treasurer also, if he has a surplus revenue at the close of each financial year in his hands, after providing for the Commonwealth requirements, has to pay the amount over to the several States in proportion to the number of their people.

Two very important Acts for enlarged powers to the Commonwealth have recently been passed, which will be submitted to the referendum this month. One provides, as regards monopoly, that when each House of the Parliament, in the same Session, has by resolution declared that the industry or business of producing or supplying any specified goods, or of supplying any specified services, is the subject of a monopoly, the Parliament shall have power to make laws for carrying on the industry or business by or under the control of the Commonwealth, and acquiring for that purpose any property used in connection with the industry or business.

The other Act contains four amendments of the Constitution, which will have to be voted upon as one issue, and provides for increasing the powers of the Commonwealth under existing sections of the Constitution, to give complete control over trade and commerce, to deal with corporations, including their regulation and control, and with industrial matters, including employment and the wages and conditions of employment, and the prevention and settlement of disputes; and, further, to add a new section giving the power to the Commonwealth to deal

with combinations of manufacturers in relation to the production, manufacture, or supply of goods or services.

One of the most important Acts recently passed by the Commonwealth Parliament is the Northern Territory Acceptance Bill, by which this territory is taken over by the Commonwealth as from January 1st last. I may remind you that this territory thus sliced out from one State and taken over by the Commonwealth is in area larger than the whole Union of South Africa.

South Australia has previously administered the area, and, in taking it over, the Federal Government assumes responsibility for the debt of about £3,000,000, spent on its development, together with an obligation to carry through certain railway works. On every ground the action taken is to be commended, as it is a national concern of Australia to develop this territory adequately.

It is well adapted for the breeding of high-class stock. It is rich in minerals. Gold, tin, copper, silver, lead, and wolframite, are the principal metals which have been found, and a geologist, the late Mr. J. E. Tenison Woods, F.G.S., once declared—"I do not believe that the same quantity of minerals will be found in any equal area in Australia."

It is the aim of the Australian Government not to lose time in proceeding with the development of the territory. At the present time an exploring party, headed by a qualified officer, is making a journey of investigation into the country.

The Commonwealth also exercises jurisdiction over the territory of Papua, British New Guinea, which is now being actively developed. A notable expedition for exploration was recently organised under the leadership of Mr. Hanniforth Smith, and we have heard with great relief and satisfaction of the safe arrival of the party at Thursday Island after very great hardships.

Railways form a most important part of the development and consolidation of a new country. It is to be noted that over 60 per cent. of Australia's loan expenditure has been spent on railways and tramways.

There are at present 16,652 miles of railways, which are State-owned and managed, with the exception of 943 miles of private lines available for general traffic, and 637 miles privately-owned, used for special purposes only. The longest railway journey that could be taken now in Australia is from Longreach in Queensland to Oodnadatta in South Australia, a distance of 3,303 miles. From Adelaide to Brisbane is 1,790 miles. Large schemes of new railways are now under consideration in the majority of the States. It is a matter for regret that the railways were laid down in the different States without the adoption of a uniform gauge, and it is recorded in the life of Mr. Gladstone that when he was Colonial Secretary he strongly urged, in a despatch to the Governor of New South Wales, the importance of adopting a uniform gauge, as regards the future of this great continent.

Unfortunately, his advice was not followed, and as the development of the country proceeds, the necessity of improved communication arises, and the disabilities of the difference of gauge and the importance of unification are more and more pressed upon the public attention.

It is now recognised that the solution of this problem would facilitate the development of commerce, and the settlement of land throughout the Commonwealth. Fresh importance has been given to this subject, owing to the recent report of Lord Kitchener on Australian defence, and the difficulties that would occur under the existing conditions in the mobilisation and transport of troops from one State to another to assist in defence.

It was pointed out by a Minister in the House that to transport 30,000 mounted troops with equipment on active service from Melbourne to Brisbane, under the present break of gauge conditions, would take sixty-three days, whereas with a uniform gauge the time occupied would be twenty-three days ten hours. At the instigation of the Minister for Defence a conference has recently been held of the chief Railway Commissioners on this matter. The Prime Minister is reported to have stated that he was strongly in favour of early action, for he regarded it as matter of urgency, quite apart from defence considerations, as the present position leads to serious economic loss. He expressed himself as favourable to some equitable principle of contribution, but pointed out, when he talked of a uniform railway gauge, that he had in mind the uniform gauge between the State capitals. The total cost of a uniform gauge scheme has been set down at £5,000,000. There are two great projects for trans-continental railways. The first is to connect the railways of the eastern and southern districts of Australia with the Western Australian line by the construction of a line between Port Augusta in South Australia and Kalgoorlie on the Western Australian goldfields, a distance of 1,100 miles. The route is being surveyed, and it is expected that as soon

as Parliament sanctions the construction, the work will be begun without delay. Then there is the second trans-continental route, which will extend the main northern line from Adelaide, at the present terminus, Oodnadatta, as far as Pine Creek, the southern terminus of the northern territory line from Palmerston. The distance between Oodnadatta and Pine Creek, on the road followed by the telegraph wire, is 1,140 miles. These lines, when constructed, will, as it were, join up the continent.

A country worth living in is a country worth defending. The Federal Government have given proof more than once that they are in earnest in the question of defence. Our national spirit of independence, a spirit which you will agree with me, is in accordance with the spirit of the British of all ages, dictates that we should shoulder our own responsibilities. But whilst the measures are directed to making adequate provision to secure Australia from attack and to protect our commerce on the coast, it is recognised that as part of the Empire the training, organisation, and equipment should proceed on such lines of uniformity with the British Army and Navy as to secure efficient co-operation when the necessity of acting together in time of war arises. Very notable and marked advance as regards both military and naval defence of the Commonwealth has been made within the last twelve months. In the scheme of the Imperial General Staff, for which Lord Haldane is entitled to a great deal of credit, we have now the means of bringing the military forces of the Empire into some form of unity, a means of co-ordination of training and maintaining a standard of efficiency.

Following this the services of Field-Marshal Lord Kitchener were obtained to report and advise on military organisation for Australia. His report and recommendations have been practically adopted, and are now being carried out in a scheme of universal training. From the first of this year every male inhabitant of Australia who has resided there six months and is a British subject will be liable to be trained—(*a*) From twelve to fourteen years of age in the Junior Cadets; (*b*) from fourteen to eighteen years of age in the Senior Cadets; (*c*) from eighteen to twenty-five years of age in the Citizen Forces. And, in the case of imminent danger of war, from twenty-five to twenty-six years of age. The obligatory training does not apply to persons reaching the age of eighteen years in or before this year. It is estimated that, apart from the Junior Cadets there will be an immediate enrolment of 100 000 Senior Cadets. When the scheme is in full operation in 1919 to 1920, it is estimated there will be 114,000 men from eighteen to twenty-five years of age undergoing a course of training, with 13,000 men between twenty-five and twenty-six in the first line of reserve, making a total fighting force of 127,000 men between the ages of eighteen and twenty-six.

The Commonwealth has been divided into military areas, and area officers will supervise and direct the registration, organisation, and training of Senior Cadets, inspection of Junior Cadets in schools, administration of troops within the area, and training of all recruits.

In order to provide for the higher training of officers a military college has been established, and the services of qualified officers on its staff have been obtained from the War Office. The education at this college will be entirely free, so as to admit of any Australians qualifying for commissions. The estimated cost of carrying out Lord Kitchener's scheme is about £2,000,000 per annum.

Now, if we turn to Naval Defence we see an equally great advance, and the adoption of a definite scheme.

At the Naval Conference held in London it was recommended that an Australian Naval Unit should be formed, consisting of one armoured cruiser, three second-class cruisers, six torpedo-boat destroyers, and three submarines. The cost of this was estimated at £3,695,000, which sum, however, owing to improvements in type will be exceeded. The annual maintenance was placed at £750,000, towards which the Admiralty or Imperial Government offered to assist with a contribution of £250,000, until such time as the Commonwealth could take over the whole cost. The Commonwealth Government, however, whilst adopting the scheme, has decided to bear from the start the whole cost, and thus relieve the Home Government of any contribution.

The armoured vessel, two second-class cruisers, and two submarines are in course of construction in England. Three destroyers are completed, and a third second-class cruiser is to be constructed in Australia.

Following on this initial scheme, the Commonwealth obtained from the Admiralty the services of Admiral Sir Reginald Henderson to advise on the whole question of naval organisation and defence, and, as you will have doubtless noted in the Press, his recommendations involve a considerable development and the creation of a fleet, including the unit now forming, within twenty-two years, consisting of eight armoured

and ten protected cruisers, eighteen destroyers, and twelve submarines, at a cost of £23,000,000. When we regard these organisations for military and naval services, and their application to the general defensive strength of the Empire, I would like to call attention to the difference there exists in working out any Imperial problem of defence for the army and for the navy. It is quite possible to train the military forces of the various parts of the Empire separately in time of peace, and yet enable them to act efficiently together in time of war, but I have serious doubts about the efficiency of navies that are unaccustomed to act together in time of peace. A navy must work in peace as it is intended to work in war. Therefore, in connection with these local navies you will see how essential it is that, beyond the adoption of a common standard of discipline and training, they should in time of peace be accustomed to act with the home navy.

There is another point. Soldiers are trained within their territorial limits. A navy is not restricted to its territorial waters. It "shows the flag," and a ship may at any moment by some action raise an international question. It is plain that this problem of the navy leads you straight to the more complex and difficult problem of Imperial foreign policy.

In industry, in commerce, and in organisation for defence, we find Australia advancing with rapid strides. I have had no time to refer to education, which would require a paper in itself.

Australia has shown, too, her eagerness to take her share in those pursuits of science in which she is best fitted to participate, and for no scientific enterprise are her conditions more favourable than they are for solar research, for which her wealth of sunshine and clear skies especially endow her. This research, fraught with great scientific importance in that it seeks to establish the evolutionary theory of the celestial universe, and pregnant with possibilities of affording an instrument of great value to meteorologists, has been encouraged by the majority of the nations, and it now remains to supply a single observing station to enable the sun to be continuously observed throughout the whole of the twenty-four hours.

A movement with which Dr. Duffield, a young South Australian of distinguished scientific attainments, is associated, has started within the Commonwealth to effect the establishment of such an observatory within the boundaries of Australia, and Mr. Deakin, when Prime Minister, was prepared, subject to the approval of Parliament, to grant Government assistance provided that the necessary funds for its equipment (£10,000) be privately subscribed. Towards this amount £4,000 has already been received.

The Commonwealth thus hopes to complete the chain of solar observatories that girdle the earth, so that Australia may take her place among the nations in the international system of co-operation in this branch of science.

I must also refer, whilst on the subject of Australian interest in science, to the share she has taken in Antarctic exploration. Not only has she contributed in money to the Shackleton and Scott expeditions, but Sir Ernest Shackleton, whom I am pleased to see here to-day, can witness to the assistance given to him by Australians, such as Professor David of Sydney and Dr. Mawson of Adelaide. Dr. Mawson is here now for the purpose of organising a scientific expedition to proceed again to the Antarctic.

I think I have said enough to show that Australia is entering on a new era. One might correctly say that the nineteenth century in Australia was the century of pioneering, and that this is to be the first century of the harvest. The first sixty or seventy years were years of the navigator and the explorer, who blazed the tracks and showed the way, and revealed in the South-West Pacific a great, new, homing land for British people. Then followed the grazier with his flocks, and we had, until the middle of the century, an almost solely pastoral country, a land of vast individual holdings, of lonely homesteads, sheep and shepherds, horses and cattle, and little else. We had a vast wealth of fertile land, but a very narrow market for produce. Development was slow, the future indefinite. Then came the gold discoveries of the "'fifties," and in a year the whole outlook was changed. We drew population from all parts of the world, and apart altogether from the great value of the gold which was won, we had at once within our doors a strong and growing market for all the produce of the land. Farming on a large scale was at once made possible, and farming men who, up to that time, might well have been pessimistic about the new country's future, saw before them all the essentials for the making of a powerful nation. The country's politics assumed a new meaning; leaders confidently prophesied a great Australian people. For the next fifty years men in all parts of Australia worked with zeal and ambition, and nearly all the way prosperity waited upon their industry. As the population grew, and settlement went out from various points and met and overlapped,

and railways were built from colony to colony, and inter-State shipping was established, there came the irresistible impulse for a Federal Union. The physical conquest of the continent, vast undertaking as it was for a handful of people, still left a few big minds time to preach national ideas and union.

The beginning of the twentieth century found what might be called the colonial days almost at an end. Australia federated into a Commonwealth, and became a young nation. That was only eleven years ago, and the world has no parallel, I think, for the wonderful changes, both in thought and action, which these few years have witnessed. The broad fact is that Australian thought has undergone a series of extraordinary changes since the days when the six colonies became the six States of a central and national Government. And I think you will agree, that not only are we changed in our thought, but also that much of this new thought is already expressed in vigorous actions, taking such important forms as a great land settlement policy and a generous immigration campaign, both of which, working together, are indispensable to our growth and our national safety.

Then you will see that we are working strongly in the fostering of young industries, in the hope that we shall become self-supporting; while we are aiming to make Australia one of the happiest lands in the world for the worker of every class; to raise the standard of our civilisation; to provide for a greater diffusion of social well-being, free of those injustices and inequalities that so blot and disfigure the civilisations of older lands. Those are what might be termed home affairs—the making of a numerous and prosperous and contented people. In matters external I have shown you we are paying special attention to defence. In short, we are embarking on a new era in local and Imperial politics, in primary and secondary industries, in defence, and in our relations to the outside world.

DISCUSSION.

The CHAIRMAN, in opening the discussion, said the Society was much indebted to Captain Collins for his address, so clear and interesting in itself, and giving some idea of how a nation had been built up, and some conception of the vast possibilities of the Australian Continent. He himself did not propose to dwell on any of the topics discussed in the paper with so great ability, but as the present occasion was the first public function he had attended since his recent appointment, he might be permitted to make one or two observations which, in other circumstances, might be regarded as entirely irrelevant. In the first place he should like to say with how much interest and pleasure Lady Denman and himself looked forward to going out to their new position in Australia, and for his part he felt deeply the responsibilities of the task he had undertaken. Compared with former Governors-General of Australia, he suffered under the serious disadvantage of being new to the work which he would have to perform. Glancing over the list of his predecessors in that high office, he saw that two of them, the late Lord Linlithgow and Lord Tennyson, were Governors of Australian States before they took office under the Commonwealth. Lord Northcote, to whom he was already indebted for many useful hints, had previously been Governor of Bombay, and the present Governor-General, Lord Dudley, had filled the great position of Viceroy of Ireland. When he reviewed the services which those gentlemen had already rendered to the Empire before they assumed the office of Governor-General, he felt acutely the disadvantages of which he had spoken, but he believed, in spite of them, or possibly even because of them, he should be able to rely upon the proverbial Australian feelings of kindliness and comradeship—qualities which flourished perhaps more abundantly beneath the warmth of a southern sun than under greyer skies at home. Whilst he realised the disadvantages, he had also one or two advantages on his side. He went out, at any rate, to take up his new appointment without any prejudice or preconceived notions. He had had the advantage—a real advantage—of having been for over four years in the personal service of the late King, who was in touch with all classes of the community in this country, and with representative men of the overseas dominions. Also, since King George had ascended the Throne, he had had the advantage of being in the personal service of His Majesty, who knew the oversea Britains as few men had had the opportunity of knowing them, and as no previous English king had ever known them. He (Lord Denman) was well aware that no man took a keener interest than His Majesty in the development and the welfare of those Dominions. He also hoped before long to have the advantage of meeting representative men, such as Mr. Fisher and other Ministers of the Commonwealth, as well as Premiers and representatives of the States Governments, from whom he looked forward to obtaining valuable information and friendly counsel. When he took up his appointment in Australia he felt sure that he would be able to rely on the cordial co-operation of the States Governors. He had already had the good fortune of acquiring, if he were permitted to say so, the friendship of the first High Commissioner from Australia to this country, Sir George Reid, who had been kind enough to give him some excellent advice, and had placed the information obtainable at his office at his disposal. There was, however, one point on which he was

afraid he would be unable to take Sir George's advice, although he realised that that advice was perfectly sound. The High Commissioner and himself were discussing the question of public speaking, on which no man was better qualified to give an opinion than Sir George Reid, and he said: "When you go out to Australia I would advise you to give up that cold, frigid, calculating style that obtains in the House of Lords at home and import more warmth and life and enthusiasm into your addresses." He (Lord Denman) was sorry to say he could not; he had been a regular attendant at the House of Lords debates for a good many years, and it would be curious if he had not acquired something of its style of speaking—at all events, its faults without its merits; and anybody who expected anything different from him would be deeply disappointed. He had alluded to the fact that he had been, and still was, in the personal service of King George, and the post that he held at the present time was that of Captain of the Corps of Gentlemen-at-Arms, a Corps which made it its proud boast that since the time of Henry VIII. it had occupied the position of the nearest guard to the English throne. He had read in some old records of a letter written, at the time when James I. succeeded to the throne, by a former Captain of the Corps, Lord Hunsdon, to King James. The writer pointed out how useful the Corps had been to Elizabeth and her predecessors. The following were the exact words used by the writer in commending the Corps to James I.'s notice: "Inasmuch as it hath served them always as a nursery to breed up Deputies of Ireland, Ambassadors into foreign parts, Councillors of State, Governors of fortified places, Commanders in the war both by land and by sea." Australia could not be called exactly a fortified place in the sense in which it was conceived by the writer of those words some three hundred years ago, but Australia was strong in her youth and her vigour, strong in the belief in her own future as a nation, confident of her own powers of development, and, above all, strong in loyal attachment to the King and to the Empire. He made no sort of claim to speak on Australia's behalf as Captain Collins had spoken that afternoon—that, indeed, was a claim to which he could never aspire; but if a few years of faithful service in the country entitled a man to give his opinions on Australian questions in the Imperial Parliament, that was a right which some day he hoped to earn.

Sir JOHN M. F. FULLER, Bart. (Governor Designate of Victoria), said he was not capable of following the polished phrases and tactful references of the Governor-General Designate; all he would say to him, if he might be allowed to, was that if he would continue to make speeches so tactful and so eloquent when he arrived in the Continent over which he was to preside, his period of office would be successful and popular. Although, like Lord Denman, he went to Australia without any prejudices, he could not claim, like him, to be a stranger to Australia. Captain Muirhead Collins to whose paper all had listened with unfeigned pleasure, had referred to the creation of the Australian Commonwealth. It happened to be his (Sir John's) privilege in the year 1891, as the guest of Lord Jersey at Sydney, to attend day by day the sittings of that historic Conference presided over by Sir Henry Parkes, which laid, and laid firmly, the foundations of the Australian Commonwealth. Ten years after, as a member of the British House of Commons, it was his privilege to take part in the unanimous vote given in favour of the Act under which the Commonwealth was created. It would be a matter of surpassing interest to him to go back twenty years afterwards to Melbourne, a city in which he received nothing but kindness and hospitality, and see the immense progress which he was sure had been made in the State of Victoria and in her capital city. Captain Collins had said, and well said, that a country worth living in was a country worth defending. Although he was fully aware that the State Governors in Australia were in no way directly responsible for the defence of the Continent, yet he thought they might be able to do a great deal to encourage and foster the spirit of Imperial patriotism, and to assist Lord Denman and his Government in building up, upon the new compulsory system, a scheme under which Australia as a continent might rest assured that she was safe against the world. Captain Collins had said that the Continent of Australia was opening a new chapter in her history. When there was a new Governor-General and a new Governor of Victoria, it was obvious that a new chapter in her history was opening. He could only say for himself, and he knew he could say it for the Governor-General Designate, that they would do their very best to make that chapter a happy and prosperous one.

Sir FRANCIS J. S. HOPWOOD, G.C.M.G., K.C.B., said he was glad of the opportunity of adding his tribute to Captain Collins's excellent work. Captain Collins had done a great deal for the country for which he felt such deep attachment, especially in disseminating amongst people a greater knowledge of its beauties, its prospects, and its importance. After all, it was knowledge that was required, both in this country and in Australia. What he (Sir Francis) thought was of more importance than anything else was reciprocity in knowledge. It would be an immense advantage for the public men of this country to have a better knowledge of the dominions oversea. Imperial conferences contributed to that end, but after all they were the debates and discussions of the gods; they did not come the way of the ordinary man. Although many people had the patriotism and the sentiment, they lacked knowledge. That knowledge was to be obtained in the course of time by the cheapening of transport facilities, by giving greater scope for easy travel, and by cheapening the cost of postage and cable communication. Cable communication was most important, because it was by cable communication that newspapers derived the knowledge

and information of which he spoke. He hoped and trusted that his friend, Sir George Reid, would, during his period of office, use his eloquent tongue for the purpose of advocating an improvement in those matters.

Sir ERNEST SHACKLETON, C.V.O., said Captain Collins had referred to the generosity which Australia had extended to him (Sir Ernest). If Captain Collins had not referred to that fact he would not have spoken, but he would say that the first official help he received on his expedition was given by Australia; three of his best men came from that country—Professor David, Douglas Mawson, and Armytage. If any word of his that afternoon could go to help Douglas Mawson's coming expedition—an expedition to gain purely scientific knowledge—in the Antarctic, he hoped it would do so. Pole-hunting expeditions were very valuable things, and he hoped the British flag would eventually fly on the Pole, but Douglas Mawson's expèdition was going out without any glamour and excitement to do great scientific work on one of the stormiest and most difficult coasts of the whole world. That expedition would be a great benefit to Australia, on account of its researches in meteorology, which told people about their crops—of which he (Sir Ernest) did not know much. Australia had helped his (Sir Ernest's) expedition, and it was therefore fitting that the people of this country and the rich Australians in it should help Mawson in his expedition.

Lieutenant-General Sir EDWARD HUTTON, K.C.M.G., C.B., was pleased at being given the opportunity of asking the meeting to convey their thanks and appreciation to Captain Collins for an able and comprehensive paper. Before referring to the paper, he would like to congratulate Lord Denman upon going out to Australia and being associated there with the most warm-hearted, kindly, and hospitable people which existed on the face of the globe. There was no part of the Empire where valuable public services, heartily rendered, were more appreciated. With reference to the paper, he would like to say a word with regard to his being selected to propose a vote of thanks to the author. It was his privilege to be in Australia during 1893-96, and to have played some part in the establishment of the Commonwealth—that was to say, when the preliminary arrangements, based upon the Federal Defence of Australia, were carried through with that object in view—and also during the three eventful years, 1901-04, which followed the establishment of the Commonwealth. During that last period he was associated with Captain Collins in Defence matters, but he (Sir Edward) would not for a moment hesitate in saying that on all points he did not agree with Captain Collins. He thought those responsible for the present system of military defence which was evolved for Australia during that period might congratulate themselves, inasmuch as that system had been copied almost line for line by Lord Haldane in the establishment of the Territorial system in this country. The evolution of the Territorial system in Australia, not unexpected on his part, had been, as Captain Collins had said, universal military service. It was possible that there might be a like development in this country. Captain Collins had remarked upon the importance of the work recently effected by Field-Marshal Lord Kitchener. In that connection he would like to supplement what the author had said in his paper, and assure the meeting, and through them the people of Great Britain and also Australia, that sufficient recognition had not been given to those devoted soldiers and statesmen who, for fifty long years before Lord Kitchener went to Australia, devoted their time, their services, and in some cases their lives, to the solution of Australian military defence. There was some reason to fear that, by the omission of any reference in Lord Kitchener's report, the valuable services of many distinguished and devoted officers, who had contributed important and lasting work for Australia's defence, extending over a long period of years, would be minimised or forgotten. He would remind the meeting that in 1859 Australia was one of the first portions of the British Empire to establish the Volunteer system, and he would further remind them that in 1885, under the guidance of that great and far-seeing statesman, the Right Hon. Thomas Dalley, New South Wales was the first self-governing Colony to establish a co-operative system of defence for the Empire, by determining to send to Suakin, at the end of the campaign in the Soudan, a contingent of infantry and artillery. The numbers were small, but it showed to the whole world the determination of Australia to take part in the defence of the whole Empire, and to establish what Mr. Chamberlain had since emphasised as the principle upon which the Empire should exist, namely, "each for all, and all for each." Australia, therefore, had reason to be proud of her military past. He might also say a word with regard to the present. It would be within the recollection of all what valuable troops were contributed by Australia to the South African War. Those services were rendered voluntarily, and Australia was actuated by the determination to promote the unity and the solidarity of the Empire. He had great pleasure in moving a vote of thanks to Captain Collins for his paper, and in doing so he congratulated him most heartily, not only upon the paper, but upon the excellent services which he had been rendering the Commonwealth of which he was so able and valuable a servant.

Mr. W. M. KELLY (Member of the Australian House of Representatives) said, as an Australian, he felt singular pleasure in seconding the vote of thanks. Every person who understood Australia would be thoroughly satisfied with the very capable way in which the subject had been handled. He felt a peculiar satisfaction in being present, because he had had an opportunity of hearing so early a statement from the Governor-General

Designate of Australia, whose speech had, to a certain extent, lightened the regret which he, in common with all Australian politicians, felt in the resignation of the present Governor-General, Lord Dudley. He (Mr. Kelly) did not appear before the audience that afternoon as a missionary of Australian virtues, because he recognised that what virtues Australians possessed they shared with their race throughout the world, and what good fortune they held they owed to the Mother Country and the white ensign of England, which had protected Australia in all the years past. He would like to say that co-operation—a word that had been mentioned that afternoon—would not solve the problem of how the great self-governing dominions could take their part in the great fabric of Imperial defence. What was meant by the phrase, "The defence of Australia"? It meant, surely, the defence of Australian interests throughout the world. A few years ago Australia's idea was to prevent any hostile forces landing upon her borders. Then she came to see that some coastal force was necessary to protect her coastal shipping, and at the present time she is beginning to realise that the trade upon which the Australians lived, and the trade routes which enabled her to get her products home to the markets of England, might be threatened just as seriously in the British Channel as in the Pacific Ocean. Again, one could not point out any section of the world and say it was the duty of any particular portion of the Empire to defend that particular section; it had to be realised that that section was part of a great whole, which must hang together if it meant to exist. He thought the problem would be solved only by co-operating in the sense of trades-union co-operation, under one single management. They were a young nation in Australia, seeking to handle national responsibilities without having all the functions of nationhood. This country possessed a Foreign Office and diplomatic missions throughout the world, to see what other people were doing and thinking; and in the light of the information acquired in that way, and in the light of the education of the Home Parliament, this country framed a continuous assurance upon the national wealth and national security. Australia, on the other hand, had absolutely no participation in "foreign affairs," and that made it extremely difficult for her to take her part continuously and systematically in the defence of the great structure of which she was so proud to form a part. He felt strongly that if Australia's defences were to be continuous, if the defences of any British dominion were to be continuous, they must be framed in the light of the developments and complications of foreign policy. He felt that if Australia or any of the other dominions were to solve the question, the solution of it would come from some close reciprocal arrangement with the Mother Country, or by some still closer scheme for foreign defence purposes only, and not through the loose system of co-operation, of which so much was spoken at the present time.

The Right Hon. Sir George H. Reid, K.C.M.G., in supporting the resolution, said he had been quite delighted with the temperature which had been prevailing during the last few minutes—it reminded him of the more active years of his own political life when he could say what he thought. Australia had been very fortunate in the character of its representatives of the Throne, and he was very glad to know, from what he had heard of Lord Denman and of Sir John Fuller, that that happy train of experience which Australia had had with one of the few visible links of the Empire at the Antipodes would be well maintained. He rather trembled when Lord Denman began to refer to some of the confidences which he (Sir George) had given to Lord Denman, because he had given Lord Denman one or two humble suggestions which were entirely unfit for publication. He had been delighted with the paper which Captain Collins had read. He had had many intimate opportunities of knowing the ability and the zeal and the successful manner in which Captain Collins represented Australia both before and since his own time, and he could assure the audience that it would have been really hard for him (Sir George) to stand the strains to which he had been subjected if he had not always had Captain Collins's thoroughly able, loyal, and efficient assistance. He supposed the audience were not at all surprised to hear that his distinguished friend, Sir Edward Hutton, had not agreed on all points with Captain Collins; he did not know any man in the world with whom his friend Sir Edward did agree, except one—and that was himself. He managed to agree with Sir Edward by saying to him: "Do what you like, and I will back you up." He would like to take the present opportunity, from a very intimate knowledge of Sir Edward Hutton, of expressing to Sir Edward, on behalf of Australia, a very profound feeling of gratitude for the great services which he had rendered in the earlier days of that country's military development.

The vote of thanks to Captain Collins was then put and carried.

Captain R. M. Collins, in acknowledging the vote, desired to say that if General Sir Edward Hutton and he did differ at times, at all events he cordially joined in the recognition of the immense services that were rendered by Sir Edward to Australia's defence. The scheme Sir Edward introduced in Australia for military defence would last some considerable time, and form the groundwork on which all future military systems would be based.

Lord Blyth, on behalf of all present, wished Lord Denman and his amiable wife long life and all happiness in their undertaking. He (Lord Blyth) was proud of being in a very small way instrumental in getting Lord Denman to take the chair that afternoon. He had had the pleasure of

meeting Lord Denman in the House of Lords for the past three or four years, and in some respects Lord Denman had been his master there. In the kindest way possible, Lord Denman had always shown members of that House how they should do their duty. Referring to Lord Denman's appointment as Governor of the Commonwealth, he (Lord Blyth) had spoken to several Peers on the side of the House on which he had the honour of sitting, and they all said, "We have got a man who will do his duty and his actions will bear golden fruit," and that expression was also borne out by several members of the Opposition. There was, indeed, perfect unanimity as to what Lord Denman was likely to do in Australia for the Mother Country, and all hoped that he would have health and strength to carry out his high ideals.

The Chairman, in acknowledging Lord Blyth's kind wish, said he was very glad to have had the opportunity of being present that afternoon, because he had met several people with whom he hoped to be closely associated in Australia, and he had also had the opportunity of listening, apart from the address given by Captain Collins, to some of the best speeches he had ever heard in his life.

Mr. C. Reginald Enock, F.R.G.S., writes:—"It is very evident to students of Australian affairs that one of Australia's greatest needs is population. But it is doubtful if the conditions offered to emigrants from Britain, good though they are, will prove sufficient in the future. I venture to urge once more the policy I have advocated; that areas of fertile Crown lands should be set aside for the use of British municipalities, to form properties to be developed by their ratepayers, and as outlets for their surplus population, present and future. The territory of Northern Australia appears to be unencumbered. Why not allocate such areas therein to every British county or city as a perpetual property, and invite capital and settlers thereto? The time will come when such properties would be of great and growing value. Australia and Canada continue to drain away the British land-working element, and to leave us our artisan element which lacks sufficient employment at home. But this process must come to an end from natural causes; whereas, if our home communities were endowed with overseas properties of their own, a field would be provided for the establishing of industries additional to agricultural ones, and a strong tie of possession and interest grow to being between the homeland and Australia. Present conditions of emigration are too hazardous for a great number of people—men and women, to say nothing of boys; whereas if organised conditions, such as suggested, were brought about, it is reasonable to suppose that a far greater number would avail themselves of them."

ARTS AND CRAFTS.

The Reproduction of Sculpture.—After two years' work, Mr. Reynolds-Stephens has brought his improved electrotyping process to such a point of perfection that he was able to show, at his studio the other day, a very beautiful and quite remarkable reproduction of his well-known group, representing Elizabeth and Philip II. of Spain contending for the supremacy of the seas in a game of chess, at which they are using ships for pawns. It is a matter of common knowledge that the reproduction of sculpture by the usual methods is anything but satisfactory: the moulds have to be made in small pieces, and owing to shrinkage and various other causes there is generally a good deal of distortion, so that the charm of a really fine original is inevitably lost. Mr. Reynolds-Stephens has realised the dangers which beset his process and set himself thoughtfully and methodically to overcome them. He made a special plaster model carefully articulated so that it could be taken to pieces for the casting, and arranged so that the joints came in convenient places. From the various portions of this model the gutta-percha moulds were taken. When once they were set, instead of being stretched slightly to get them off —with the natural result that they did not return to exactly their original lines—they were bound with metal to keep them in shape, and then the plaster was simply broken out of them, with no attempt to keep it intact. Thus the moulds, when they came to be fitted together, joined exactly without having to be pulled into place, and the reproduction taken from them by means of a process of electro-deposit of copper, is an exact facsimile of the original piece of sculpture. The sculptor in this case has finished off the group by tinning the damask pattern of Elizabeth's dress, and by inserting pieces of mother-of-pearl, etc., in the trimmings of the costumes, and enamelling Philip's jewel of the Golden Fleece, so that this particular piece of work represents, besides the bare result of the process, a good deal of the artist's own labour and thought; but no one who has seen Mr. Reynolds-Stephens's trial piece can doubt the success of his process or remain unconvinced of the possibility of worthily reproducing sculpture by his new method. It is to be hoped that some proportion of those who will probably see it at the May exhibition of the Royal Academy will realise what it really means.

The Salting Bequest.—All students of applied art who have been in the habit of visiting the Victoria and Albert Museum, are well acquainted with the name and fame of the late Mr. George Salting, but since the bulk of his collection has hitherto been distributed through the museum, probably very few people realised the extent of his bequest to the nation until they saw the whole housed in its new quarters. It is, indeed, a bequest extraordinarily well worth having. The wonderful collection of pottery includes

Henri II. ware, Palissy ware, Italian Majolica, Hispano-Moresque work, Persian and Syrian pottery, and a splendid muster of Chinese porcelain. And pottery is only a fraction of the whole which includes, among other things, really valuable examples of woodwork, *cuire bouilli*, ironwork, ivories, cut jade, lacquer work, and applied art of almost all kinds.

It seems, perhaps, hardly generous to look a gift horse in the mouth, and one can appreciate the feelings of a collector who wishes the world to know the extent of the collection he leaves behind him; but from the point of view of the nation at large, it is a thousand pities that the works of art, which, according to the terms of Mr. Salting's will, are shown at South Kensington in rooms apart from the rest of the exhibits, cannot, after a brief display by themselves, take their place in the general galleries and be included in the ordered sequence of the newly-arranged museum. The present grouping of the objects reflects credit on whoever was responsible for their arrangement, and the plan which places the Chinese and Japanese porcelain on the second floor, rather beyond the end of the main pottery collection, is specially to be commended; but, though this is an excellent expedient under existing circumstances, it is scarcely an ideal arrangement.

All-British Applied Art.—The All-British shopping week offered incidentally an opportunity of seeing a good deal of English industrial art. There was a little exhibition of British lace held in Wigmore Street, under the patronage of the Queen and other members of the Royal Family, at which plenty of good Buckinghamshire, tambour, Honiton, and other laces were shown, though some of the best Devonshire industries were not represented. Good specimens of Lancastrian, Ruskin, Doulton, and other pottery were displayed by a number of shops and dealers, and must have given the man in the street rather a surprise if he stopped to think about them. Waring's exhibited some beautiful examples of brocades and damasks, woven at Spitalfields and Braintree. It would have been interesting to have seen some of these labelled and arranged side by side with French goods, for they certainly looked as if they would compare by no means unfavourably with silks woven at Lyons and Paris. There were a number of pretty prints and chintzes about—and the centre of one of Liberty's windows was occupied by a fine bold pattern called the golden pheasant, block-printed on a specially woven ground. A large number of colours were employed and it could not have taken far short of thirty blocks to print the design as it stood. A *tour-de-force* is not always artistically happy, clever as it may be technically, but this particular effort, which in its way was as fine as a piece of tapestry, was very well worth the trouble taken to produce it.

The Sir John Cass Arts and Crafts Society.—The Sir John Cass Arts and Crafts Society held its annual exhibition at Sloane-street this year, and the exhibits were quite up to their usual high standard. Mr. Harold Stabler, besides some work which had been exhibited elsewhere, showed a very pleasingly-shaped silver ciborium decorated with well-chosen vine ornament. Mr. Kruger sent some admirable decorative sketches, Mr. Gilbert Bayes some charming little statuettes, particularly a tiny knight in armour, which was most attractive; Mr. Manwaring contributed some very satisfactory pieces of lettering and illumination. With these exceptions the show consisted mainly of jewelry, of which there was a very creditable collection. The old Sir John Cass students have, as a rule, much more feeling for design than the ordinary run of school-trained jewelers, and by far the greater part of the objects shown at Sloane-street were well considered and well planned, and had a certain distinction of style which most "art jewelry" lacks. Miss Kirkham exhibited a very attractive clasp, besides a very dainty chain and pendant; Miss Violet Ramsay was represented by a case of work in which the right relation of the stones to the silver work was very well maintained, and Miss Shipwright's chains showed a good deal of fancy in the designing of the links, whilst several other ladies showed interesting work.

GENERAL NOTES.

Loan Funds for Women.—The report of the Society for Promoting the Employment of Women, recently read at the fifty-second annual meeting, over which Lord Balfour of Burleigh presided, contains an interesting account of the year's work of a body which is not so well known as it deserves to be. Established over half a century ago, the society has done admirable work as a pioneer in opening up new professions and occupations for women, and in endeavouring to fit them by systematic technical training for such positions. To assist and encourage girls whose circumstances do not enable them to incur the necessary expenses to secure this training, the society has instituted a series of loan funds. The rules under which they are administered are very simple. The amount of the loans is limited to £30. The grantee, or, if she is under twenty-one, her father, has to sign an agreement that she will complete her training; that she will repay her loan, without interest, after her training is finished, by instalments of three shillings out of every pound she earns; and that she will keep the society informed of her engagements, earnings, and address until the whole of the loan is repaid. Someone in a responsible position must guarantee that she will keep this agreement faithfully. If she fails to do so, the guarantor is responsible for the loan or any portion of it that has not been repaid; but if she is faithful and honest the guarantor is never troubled. The death of the grantee cancels the debt. The first of these loans was granted in 1897, and since that date

there has been an almost constant increase in the amounts granted. For the present year the total is £544, while the repayments amount to nearly £400. It is gratifying to know that it is quite exceptional for a grantee to shirk the responsibility of repaying her loan. As a rule, the instalments are repaid with great regularity, and the extracts from letters which are printed in the report show what a great boon the loans have proved in many cases. Frequently they are the turning-point in a girl's career, and save her from joining the army of unemployables who, while willing to work "in any capacity," are qualified in none. The committee make an urgent appeal for funds to enable them to carry on and extend their work. The appeal was strongly endorsed by Lord Balfour of Burleigh, and there can be no doubt that any money subscribed to the funds of the society will be put to the excellent purpose of helping people to help themselves.

The Galton Chair of Eugenics.—Sir Francis Galton, F.R.S., who died in January last, left his residuary estate to the University of London for the purpose of encouraging the study of eugenics. The residuary estate will amount to some £45,000, which is to be devoted to the establishment of a Chair. The duties of the Professor will be (1) to collect materials bearing on eugenics; (2) to discuss such materials and draw conclusions; (3) to form a central office for the provision of information concerning the laws of inheritance in man; and (4) to extend the knowledge of eugenics by professorial instruction, occasional publications, public lectures, etc. In his will, Sir Francis Galton expressed the desire, though he did not impose it as an obligation, "that on the appointment of the first professor the post shall be offered to Professor Karl Pearson, and on such conditions as will give him liberty to continue his Biometric Laboratory now at University College."

Population of Bosnia and Herzegovina.—The civil population of Bosnia and Herzegovina, according to a census just taken, amounts to 1,895,673 inhabitants at the present time. This shows an increase of 327,501 persons since 1895, or 20·87 per cent.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

April 26.—Noel Heaton, B.Sc., F.C.S., "The Production and Identification of Imitation and Artificial Gems."

May 3.—A. W. Gattie, "London Transport." James Swinburne, M.Inst.C.E., F.R.S., will preside.

May 10.—Hal Williams, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

May 17.—Professor Raoul Pictet, "Les Basses Températures."

May 24.—Frank M. Andrews, "Architecture in America." Sir Aston Webb, C.B., R.A., F.R.I.B.A., will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

April 27.—Sir Thomas Henry Holland, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India."

May 25.—W. R. H. Merk, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

Colonial Section.

Tuesday afternoon, at 4.30 o'clock:—

May 9.—F. Williams Taylor, "Canada and Canadian Banking."

Cantor Lectures.

Monday Evenings, at 8 o'clock:—

Alfred E. H. Tutton, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

MEETINGS FOR THE ENSUING WEEK.

Wednesday, April 19...Meteorological, 25, Great George-street, S.W., 7.30 p.m. 1. Mr. W. Marriott, "Variations in the English Climate during the thirty years, 1881-1910." 2. Captain C. H. Ley, "The Value of the Two-Theodolite Method for determining Vertical Air-Motion." 3. Captain C. H. Ley, "An Automatic Valve for Pilot Balloons."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. E. J. Spitta, "A Report on the Grayson's Rulings presented by Mr. Conrad Beck to the Royal Microscopical Society." 2. Mr. E. J. Sheppard, "The Reappearance of the Nucleolus in Mitosis." 3. Señor Domingo de Orueta, "Apparatus for Photomicrography with the Microscope Standing in any Position, especially in Inclined Position." 4. Mr. James Murray, "Canadian Rotifers collected by the Shackleton Antarctic Expedition, 1909." 5. Mr. E. J. Spitta, "Low-power Photomicrography with Special Relation to Colouring Methods."

Thursday, April 20...Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. G. H. Rodman, "Stick Insects."

Numismatic, 2, Albemarle-street, W., 6.30 p.m. Mr. G. F. H l, "A Find of Ancient British Coins of a New Ty e."

Friday, April 21...B ewing, Institute of (Yorkshire and North-Eastern Section), Queen's Hotel, Leeds, 8 p.m. Mr. T. Fairley, "The Collection, Composition and Treatment of Water-supplies suitable for Brewing and other Purposes."

Municipal and County Engineers (Metropolitan District Meeting), Caxton Hall, Westminster, S.W., 7.30 p.m. Discussion on the following papers:—1. Mr. A. J. Price, "Pumping Plant for Sewerage and Water Works." 2. Mr. W. Ransom, "Filtration and Purification of Water for Public Supply."

Saturday, April 22...Municipal and County Engineers (Home District Meeting), Town Hall, Croydon, 10 a.m. 1. Mr. George F. Carter, "Some of the Public Works of Croydon." 2. Mr. E. F. Morgan, "Permanent Way and Highways in Croydon." 3. Visits to Public Works.

Journal of the Royal Society of Arts.

No. 3,048. VOL. LIX.

FRIDAY, APRIL 21, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, APRIL 26th, 8 p.m. (Ordinary Meeting.) NOEL HEATON, B.Sc., F.C.S., "The Production and Identification of Imitation and Artificial Gems." Principal HENRY A. MIERS, M.A., D.Sc., F.R.S., will preside.

THURSDAY, APRIL 27th, 4.30 p.m. (Indian Section.) Sir THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Sir ARUNDEL T. ARUNDEL, K.C.S.I., will preside.

CONVERSAZIONE.

The Society's Conversazione will be held this year at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday, May 30th, from 9 p.m. to 12.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

CHINESE NATURAL PHILOSOPHY AND MAGIC.

By Professor HERBERT CHATLEY, B.Sc.

I.—THE CHINESE THEORY OF THE UNIVERSE.

Within the last few years there has been a rapid assimilation of Western science by the intellectual classes of China, and it may perhaps be feared that, as in Japan, the old knowledge of China is being forgotten. It is, nevertheless, quite demonstrable that the early Chinese ideas as to cosmogony and physics have a basis far sounder than that of the Greek philosophy, which was so long the pabulum of the European scholars. In fact, the dominant idea of mathematical order and relation of effect to cause appears in the Chinese classics in so definite a form that several very striking analogies are presented between the native philosophy and modern science.

The general system seems to have been best described by the sage Ch'u Hsi, who lived in the 12th century A.D. (Sung⁴ 宋, dynasty). According to this philosopher, all things (萬 物 wan⁴ wu⁴, "the manifold") were produced from the Great Absolute (太 極 t'ai⁴ chi⁴, "the ultimate limit") by differentiation into the Yang² (陽) and Yin¹ (陰), which again differentiated and combined into all the countless varieties of things. The words Yang² and Yin¹ are usually translated male and female principles, but would seem rather to mean brightness and shadow, or, in modern terms, positive and negative.

All these changes (變⁴ 化 pien⁴ hua⁴, "metamorphoses") occur in accordance with four principles :—

1. Li³ (理) order.
2. Shu⁴ (數) mathematics.
3. Ch'i⁴ (氣) breath or motion.
4. Hsing² (形) form or outline.

The idea seems to be that each change takes place in accordance with immutable principles (Li³), following mathematical order (Shu⁴), the change proceeding as a motion (Ch'i⁴), and manifested by the form (Hsing²).

If we compare this system with the modern scientific scheme by which things are evolved ("pien hua" seems to mean "evolve" as nearly as possible) from the primitive matter (Crookes' "protyle" or the ether of the physicists) as positive and negative electrons (J. J. Thomson), such changes proceeding according to a regular law expressible mathematically, involving motion and manifest in the phenomena, the analogy is seen to be complete. It may be that the lines of resemblance are stretched

somewhat, but certainly the parallelism is remarkable. The next feature in this extraordinary philosophy is the system of the Kua[4] (卦) figures. The two elemental principles of the Yang[2] and Yin[1] were conceived to have paired in all possible ways, making the four superior Kua[4] (四 象 szu[4] hsiang[4], the four images or stars), which again combined with the elemental forms so that we have eight combinations, each containing three constituent elements (the Eight Diagrams 八 卦 pa[2] kua[4]). These again combined with one another to produce sixty-four "kua[4]" combinations, These sixty-four, each containing six yao[2] (爻) or Yin[1] and Yang[2] elements, produce 384 variations. The order and names of the sixty-four combinations and their mystical symbols are given in the Yih[4] Ching[1] (易 經 = Book of the Change), together with commentaries by various scholars attempting to explain them by ethical and cosmological analogies. Originally there seem to have been three versions of the Yih[4] Ching[1]—the Lien[2] Shan[1] (連 山), the Kuei[1] Ts'ang[2] (歸 藏), and the Chou[1] Yih[4] (周 易), ascribed respectively to Shen[2] Nung[2] (神 農) *circa* 2700 B.C., Huang[2] Ti[4] (黄 帝) *circa* 2600 B.C., and to the founders of the Chin[1] dynasty *circa* 1200 B.C. The Eight Diagrams in their natural order are ascribed to the prehistoric emperor Fu[2] Hsi[1] (伏 羲) *circa* 2800 B.C., who is said to have observed them on the back of a tortoise. Associated with these early speculations are the map of Hê[2] (河) and the chart of Lê[4] (洛), which are composed of numerical arrangement of the Yang[2] and Yin[1]. The notion of the universe as having originally developed from a mathematical arrangement of units appears in philosophical history many times. The essential idea occurs in Lucretius, and is elaborately stated in the cosmogony ascribed to the Pythagorean school (see G. R. S. Mead's book on the Gnostics "Fragments of a Forgotten Faith"). The Sephiruth of Hebrew Kubbalu are quite analogous,* and finally we come on the same idea in Professor J. J. Thomson's recent mathematical theories as to the electronic constitution of the atom.† He shows that the only stable arrangement of the electrons involves a system of concentric polyga (or polyhedra); the number of electrons depending on the degree to which this concentric order is developed. The importance of numerical arrangement in the constitution of matter is also seen in the atomic theory of chemical combinations. Although this analogy between modern science and the mystical speculations of the ancients may not be of any real import, it is rather noteworthy, and would seem to imply that some of the old philosophers intuitively arrived at some of the more important conceptions of experimental physics.

As far as the Kua[4] figures are concerned, it may of course be contended that once the idea of a fundamental duality is conceived (analogous to the main dogma of Mazdaeism), the combinations naturally suggest themselves by mathematical reasoning. Even if this be so, it was certainly a great advance to have conceived that matter is necessarily composed of all the possible combinations of two elements, taken in groups of certain numbers progressively.

The moment, however, we begin to examine the connections which the Chinese sages drew between the combinations and actual phenomena, we find ourselves in the region of empiric or occult reasoning, based purely on analogy. The simple Kua[4] combinations of elemental principles are by them identified with very complex phenomena, with which there is no apparent connection. If we suppose that these phenomena are merely types of those conditions or states which the Kua[4] figures are intended to symbolise, some assistance may perhaps be gained; but it is necessary to be very cautious in making any such assumptions, since the mere desire to magnify the value of these antique concepts may be the mainspring of our action.

In the ode which appears at the beginning of the Yih[4] Ching[1] (周 易 卦 歌 Chou[1] Yih[4] Kua[4] Kê[1]) the eight Kua[4] are said to have made (爲 wei[2]) the eight natural phenomena:—Heaven, Moisture, Fire, Thunder, Wind, Water, Mountains, Earth. (See table on p. 559.)

It is conceivable that originally the diagrams were merely intended to signify the different states of matter suggested in the table, although there is of course the usual objection to this—that concrete ideas generally precede abstract ones.

It seems doubtful whether any useful purpose will be served by endeavouring to identify the meanings of the sixty-four Kua[4] on the same lines; but, presumably, *if* the eight Kua were intended in the manner suggested, the sixty-four extended the system.

* When studied by means of the Gematriyah or numerical system of divination, or the thirty-two "paths" of the Sepher Yetzirah.

† Prout's obsolete hypothesis of atomic constitution is analogous, and indirectly led to Mendeleeff's law, of which Thomson's theory is a development.

The scheme may be shown in a table, as follows:—

Kua[4] Figure.	Name.	Meaning of Name.	Natural Phenomenon.	Possible Significance.
☰	乾 Ch'ien[2]	dry, to come out	Heavens	Change (commencement of).
☱	兌 Tui[4]	to exchange	Moisture (澤)	Permeability.
☲	離 Lí[2]	to separate	Fire	Repulsion.
☳	震 Chên[4]	to quake	Thunder	Vibration.
☴	巽 Sun[4]	mildness	Wind	Equilibrium.
☵	坎 K'an[3]	a hollow, uneven	Water	Heterogeneity.
☶	艮 Kên[4]	obstinate	Mountains	Rigidity.
☷	坤 K'un[1]	yielding	Earth	Plasticity.

II.—Chinese Magic.

The system of occult philosophy upon which magical practices are based in China is practically that outlined in the above sketch of the theory of the universe. The manner in which a series of occult associations of ideas has been formed is described in the following:—

Eitel, "Feng-Shui, or the Rudiments of Natural Science in China." Trübner, 1873 [No. E. 896. Tientsin Municipal Library].

Carus, "Chinese Occultism," in the *Monist* (quarterly review), vol. xviii., p. 510.

De Groot, "The Religious System of China."

The system of magic variously called Feng[1] Shui[3] (風 水) Ti[4] li[3] (地 理), or k'an[1] yü[2] (堪 輿), professes to decide as to propitious times and places, and is more properly termed augury, but as far as the author can discover, the same principles underlie the ritual of the invocation of spirits, divination (prophecy), and thaumaturgy (the working of miracles). At the present time it seems to be only employed in three ways:—

1. The discovery of propitious times and places for the building of houses and the construction of graves. [This depends on an astrological scheme which indicates the *locus* and value of the Yin[1] and Yang[2] at any time or place, and the analogous conditions indicated by the topography.]
2. Fortune-telling.
3. Gambling.

The last-named is generally the final form of a system of divination. The use of cards is said to be derived from the Turot cards which were originally employed for occult purposes. The legend which ascribes the invention of cards to the purpose of amusing a mad king does not seem at all a sufficient explanation, and there is in addition the fact that cards of a kind existed before the said king. In further support of this idea, the well-known practice of telling fortunes by cards may probably be regarded as a survival of a regular form of divination by such means. It seems, in fact, probable that card-playing for stakes is a mere development of a ceremony in which individuals consulting the oracle decided to abide by its pronouncements as to the holding of disputed property.

Dice and dominoes (which are obviously related) serve the same purpose, and are probably related to the Kua[4] Diagrams. The teetotum and the gambling dials used in various games come within a similar category, which includes all arithmetical methods of determining chances.

The occult origin of these games of chance may explain the old ecclesiastical prejudice against them which always had a keen eye for "La magie noire."

The Chinese method of gambling with a number of sticks, such as one sees in Chih-Li, is obviously based on the methods of divination described in the Yih[4] Ching[1]. (In the chapter called 筮 儀 shih[1] i[2], "The Rites of Divination.")*

Divination.

There can be little doubt, when one studies the different forms of divination, that it was the ancient belief that any group of different units whose arrangement after a process of shuffling

* All these sections of the Yih[4] Ching[1] are modern (*i.e.*, written during the Christian Era), but the commentaries on the ancient text, which are of Confucian era, give them logical support.

was impossible to predict would serve for purposes of prophecy, the unseen powers being able to affect the slight variations of circumstance which determine the final configuration, while those initiated into the code explaining all the possible configurations were thereby able to interpret the will and knowledge of the unseen powers. In various occidental and oriental books on occultism, the diviner is directed to concentrate his attention on the object to be known, presumably so that he should become a responsive medium to the spiritual influences, who would so control his nervous and muscular actions that in the process of shuffling a prophetic configuration of the units would be produced.

In the above-mentioned chapter of the Yih[4] Ching[1], after elaborate preparations of the place in which the divination is to be performed and the burning of incense, a conjuration has to be recited and then by a process of shuffling fifty sticks into two or three groups, and counting out the odd sticks by cycles of eight, the two parts of one of the sixty-four yao[2] are determined. The sections of the Yih[4] Ching[1] which explain (!) the meanings of each of the yao[2] are then to be consulted, and the oracular reply is in accordance therewith.

A critical examination of the early forms of the Chinese characters referring to occult practices show that the Tortoise-shell (which is now a figure of speech for the Pa Kua, but anciently was used in the same manner as shoulder-blades, being scorched and its cracks and marks examined) and stalks have from times immemorial been employed to divine the future. The distinction of lucky and unlucky into "Straight or whole," and "Broken or crossed," also shows the antiquity of the Yin and Yang figures.

With regard to the Kua system of divination, it is one of the simplest and most scientific (if such a word is appropriate) of all the systems employed by the higher civilisations. It recognises *ab initio* that circumstances can only combine according to the mathematical law of permutations, and carefully tabulates all the possible results for eight units. By means of stalks or counters the prophetic configuration is simply found and the book of oracles consulted. From a psychological point of view four aspects of this process present themselves:—

1. The shuffling is wholly controlled by chance and the oracle bears no relation to the events concerned.

2. The shuffling is manipulated by the conjurer and the oracle bears a relation determined by his mind.

3. The shuffling is controlled by the subconsciousness of the operation, so that the relation of the oracle to the event is determined by the "infra-mind" or "subliminal self." *

4. The shuffling gives opportunities for extra-carnate beings to influence the nervous system so that the fingers are controlled to produce an appropriate configuration and prophetic oracle. According to magical dogma, this would necessitate the prior production of a receptive and passive state of mind in the operator such as would doubtless follow from an adherence to the ritualistic instructions of the Yih Ching.

Which of these occurs in any particular case may be left open to discussion.

Dr. Carus has suggested that the Judaic Urim and Thummim were of a similar character to the divining stalks. Certainly the divining arrows of Hezekiah are analogous. It is possible that the Jewish priests had a book of oracles similar to the Yih Ching, which interpreted the different groupings of the oracular symbols. The Babylonian text-books (or bricks) on omens indicate a similarly systematic arrangement of oracles. Possibly the Roman Sibylline books also served such a purpose.

Invocation of Spirits.

In an essay by the author on "Mediæval Occultism," published in the *Monist*, an attempt has been made to demonstrate that magical or religious ritual is a form of "suggestion." As a corollary, it follows that the whole of a magical ceremony is a species of auto-hypnosigenesis culminating when successful in a state of ecstasy, which differs from the usual comatose condition in that the operator retains some control over himself. On this hypothesis, the invocation of spirits (conjuration) consists of the following parts:—

1. A preparation of the mind, generally extending through years, which forms a belief in the existence, order, and nature of the spiritual world.

2. A specific preparation of the mind and body for the particular ceremony, generally consisting of a course of abstinence and meditation.

* This of course contradicts the scholastic dogma "Q Nihil est in intellectû quod non prius est in sensû," but modern psychology casts grave doubts on the literal accuracy of this aphorism.

3. A ceremony consisting of a ritual and conducted in such a place that every detail of environment, conduct, and thought, tends increasingly to suggest the desired thaumaturgic result.

Whether such a result accrues or not (*i.e.*, within the subjective experience of the operator, but with the appearance of objectivity) depends on the thoroughness of the preliminary training, the temperament of the individual, and the nature of the extraneous circumstances under which the ceremony is performed. It necessarily involves mental strain, and may lead to madness. [This possibly explains why many primitive races have considered lunatics as divinely possessed, seeing that in such a state of civilisation madness would probably be more frequently induced by this cause than any other.]

We may then divide the consideration of Chinese exorcism (this word really means "casting out spirits," but has come to mean invocation also) into three parts:—

1. The beliefs as to the world of spirits.
2. The rules for the life of a magician.
3. The ceremonies of an act of exorcism.

Beliefs.

In all religions we usually find the spirits arranged in a kind of hierarchy, and their attributes and rank are functions of their position in this hierarchy. The circles of angels described by pseudo-Dionysius-Areopagiticus as inhabiting the Christian Heaven, and the scheme of Buddhas, Bodhisatvus, and Manusibuddhas which appear in the Mandala or world-scheme of Northern Buddhism, are good examples of this idea.

The native Chinese system of spirits, as far as it can be separated from Buddhist influences, does not show any very great regularity.

There seem to be three great classes of spirits:—

神 shen^2, usually translated spirit.
鬼 kuei^3, usually translated devil or ghost.
仙 hsien^1, usually translated fairy or jinnee.*

The three characters seem to be very ancient, and are of a simple formation. The first, 神 shen^2, appears to be the "suggestive compound" type, consisting, as it does, of the two parts 示 shih^4, "to reveal," and 申 shen^1, "to expand."

The second, 鬼 kuei^3 is a radical, and is probably a hieroglyphic. It is rather interesting to notice in this connection the Buddhist character 甶 fu^2, which means a "devil's head." It is, doubtless, not necessary here to point out that the word "devil" is not to be taken in a European sense, but simply as meaning a spirit of less stability than the shen^2.

The third, 仙 hsien^1, is again apparently a suggestive compound, consisting of 人 jên, a man, and 山 shan, a mountain. The association of a kind of elemental spirits with mountains occurs in the folk-lore of all countries. (*Cf.* Arabian "Jinn" of Mount Kâf, and the spirits of the Hartz Mountains.)

The words 神 shen and 鬼 kuei are also used to signify the animus and anima of human beings, *i.e.*, the immortal and astral parts of the human economy. This, of course, falls in well with the doctrine of apotheosis.

Some details of the system are to be found in the Guide to the Musée Guimet of Comparative Religions (Paris), compiled by M. L. de Milloné, Professor J. J. M. de Groot, Terrien de Lacouperie, and Tcheng-King. There we find:—

1. The Trinity of Divinities of Fortune:—

福神 Fu^2 shen^2, presiding over rank and honours.

祿神 Lu^4 shen^2, presiding over emoluments and generation.

壽神 Shou shen, presiding over longevity (identified with Lao-Tze).

2. The Eight Spirits (八神 pa shen^2):—

鍾離 Chung^1-Li^2.*
曹國舅 T'sao-kuo-chiu.*
張果老 Chang-kuo-lao.*
藍采和 Lan-tsai-ho.*
何仙姑 Hô-hsien-kû (fem.).*
呂東嵒 Lü-tong-pin^3, worshipped under name of 純陽 Ch'un^2 yang^2 (Pure principle).
韓湘子 Han-hsiang-dzu.
李鐵拐 Li-tieh-kuai.

All these eight are supposed to have once lived on earth, and during their terrestrial existence practised asceticism and performed great miracles.

Chung-Li was a general of the Han dynasty, and retired during a military expedition to Thibet to become a hermit in the mountains. Ts'ao-kuo-chiu is also said to have lived as a hermit, mortifying himself for the sins of men. Lan-tsai-ho, after a life of austerity, is said to have been translated to heaven without dying. Ho-hsien-kû was a woman, and is said to have had the power of miraculously moving from

* See also animal spirits referred to later.

* These are nominally Taoist, but the Guimet authorities regard them as aboriginal.

place to place. Lü-tong-pin was a great scholar and a Taoist writer; under the instructions of Chung-Li he became a great exorcist. Han-hsiang-dzu is credited with many miracles, and Li-tieh-kuai is said to have died by mischance during a projection of his spirit from the body. Chang-kuo-lao is, like Balaam, principally noted for the possession of a miraculous donkey.

There is yet another Triad of Gods of the Hearth :—

觀 音 Kuan^1-yin^1, protector of children.

Tou-ti-Kung or Ko-lung, god of wealth.

Tsao-Kung-Kung, god of fire and the domestic hearth.

These three deities figure in the ancestral hall to the right of the tablets.

We have again Seven Gods of Luck (七 福 人 ch'i fu jen), to whom special importance is attached in Japan (Shichi-fuku-jin).*

Finally, there are a number of special deities with different functions.

西 王 母 娘 娘 Kin-mou or Si Wang-mou, goddess of the Kuen Lun Mountains. [The Heavenly Mother of the West.]

Shin-to, god of doors.

Huan-ming, god of winter.

城 隍 Ch'eng-huang, generic name of the two protectors of towns, of whom one (the Sing ong ya) guards walls and moats of walled cities, and exercises surveillance over the actions of the inhabitants, and acts as agent for Yên^1 lo^1-wang^2, the Buddhist god of death (閻羅王).

關 帝 Kuan^1-Ti, god of war.

Doubtless many of the Taoist divinities are really native gods, but it is difficult to separate them. The supreme deity, 皇 天 上 帝,† Huang^2 T'ien Shang Ti, the celestial prototype of the Emperor of the 天 下 (T'ien Hsia), figures in both Taoism and Confucianism, but more generally it would seem to be impossible to discriminate between this god and 天 T'ien, which signifies the sum total of the heavenly influences.‡

As in India and Egypt, there is a strong local character about the spirits, the importance of such apparently varying inversely as the extent of their influence. Primarily we have the ancestral spirits (神 主 shên^2 chu^3, spirit-lord), or (祖 宗 tsu^3 tsung^3), commonly translated "ancestors," but apparently having a hieroglyphic meaning of "the numerous (且) watchers (示) of the home" (宀, a roof). Secondarily, we have the three gods of the hearth above referred to. Thirdly, there is the local god (土 地 神 t'u ti shên). Fourthly, occur the Ch'eng Huang (literally Town Moat*), mentioned above. Fifthly, we have the gods of special localities, who are probably developments of the 大 社 ta^4 shê^4, the tutelary deities who influence land and agriculture.

Superimposed on this animistic system, we have the literary cult of the philosophers in its Confucian and Taoist forms, the saintly hierarchy of the Buddhists, and the imperial worship of the heavenly and earthly influences. The last seems to be an intensification of the local rites, the Emperor acting as the Chief Priest of the country in the same way as the senior male of the household does for the family. In connection with this, the ceremony of ploughing, performed by the Emperor annually at the capital, bears a close analogy to the sacrifices, human, animal and symbolic, made by many primitive races in connection with agriculture. According to Wells Williams ("Middle Kingdom," pp. 108 and 99), on the occasion of this imperial ploughing, a large clay cow, accompanied by or containing numerous small images of a cow, is broken up and the fragments are distributed over the fields. A similar ceremony is performed in each of the provincial governments. Williams gives the following references in support of this:—"Penal Code," pp. 94-106, 526; "Chinese Repository," vol. ii. p. 350, vol. iii. pp. 121, 231, vol. v. p. 485; "La Chine Ouverte," p. 346; and "Foreign Missionary Chronicle," vol. xiii. p. 296.

There is yet another type of spiritual influence which is greatly credited in the Chinese Empire, and is apparently endemic, namely, the animal-demon. Chinese fiction and legend abounds with the exploits of these supernatural beings, who possess the power of metamorphosis from animal to human forms, and *vice versa*. These are generally known as 狐 hu^2, or witch-forces. The notion of the transformation of sorceresses into animals is quite widespread, and there are

* The most popular is 財 神 T'sai^2 shen, the spirit of wealth.

† Or 玉 皇 上 帝 Yü Huang Shang Ti, the present ruler of the universe. [The Precious Imperial Exalted Ruler.]

‡ All these divinities, regardless of their present celestial rank, are identified with deceased men and women, and it would doubtless be more correct to specify the Chinese hierarchy as a system of official ranks at present occupied by souls of these names. The cult varies from mere formal respect in pure Confucianism to absolute worship in the lower forms of Taoism.

* It would be interesting to know if in ancient times these town gods were created by human sacrifice, as in other countries was the case.

particularly strong associations with canine animals. The witchcraft literature of Europe contains repeated references to the metamorphosis of witches into foxes and *vice versa*, and the Eastern European beliefs in the were-wolf and the vampire are analogous. This class of spirits is known to European occultists as "familiar," and is apparently less noxious than the devil tribe.

In China the spirits may be arranged in the following order:—

神, 仙, 狐, 鬼, Shen, Hsien, Hu, Kuei.

The 神 Shen, and 鬼 Kuei, are the two poles of beneficence and maleficence respectively, and the intermediate varieties are respectively good and bad elemental spirits. In terms of the human economy, the 神 Shen, would seem to stand for the highest faculties, the 仙 Hsien, for the pure and pleasing emotions, the 狐 Hu, for the spirit of mischief and irresponsibility, and the 鬼 Kuei, for the darker passions and blackest depths of the mind. These conditions projected by the imagination on to the fabric of thought (the occultists' "Astral Light"), give rise to the conceptions of spirits of all these types.

It is very noteworthy that all the supernatural beings of Chinese mythology are believed to have been originally living men or women, so that the system is perfectly animistic.

Astrology.

In addition to these personal deities, to whom (unless they be immediate ancestors) no great respect is shown, we have a number of natural forces based on the astrological exposition of the Yih Kua system. In accordance with the first law of Li[3], the heavens control the earth and its inhabitants. The exact manner of this control gives rise to a system of astrological parallels. The "four figures" are symbolised in the heavens by the Sun, Stars, Moon and Planets.

太陽 T'ai Yang is the name of the Sun.

少陽 Shao Yang is the name of the Fixed Stars.

太陰 T'ai Yin is the name of the Moon.

少陰 Shao Yin is the name of the Planets.

It is somewhat curious that the Yang bodies are those which we now know to shine by their own light, whereas the Yin bodies are those which shine by reflected light, but probably the discrimination was made on account of the invariability of the light of the Sun and Stars as compared with variability of the light of the Moon and Planets. The apparent daily rotation of the Sun is also symbolised by the Fu-Hs arrangement of the Kua, in which the Chien Figure (☰) takes the South position, and the K'un[1] (☷) the North, the Li[2] (☲) takes the East, indicating the predominance of Yang (light) over Yin (darkness) as typified by the rising of the Sun, and the K'an[3] (☵) figure takes the West, indicating the predominance of darkness (Yin) over Light (Yang) as typified by the rising of the Sun; the Tui[4] (☱) in the S.E. and the Sun[4] in the S.W. (☴) respectively indicate the increase and decrease of Yang (Light) as typified by the ascent and descent of the Sun, and the Chên[4] (☳) in the N.E., and Kên[4] (☶) in the N.W., respectively indicate the decrease and increase of Yin (darkness), typified by the ascent and descent of the Sun to and from its Northern depression. This arrangement is of course only applicable to the Northern Hemisphere of the Earth, and serves to explain the fact that the Chinese compass-needle points *South* (*i.e.*, in the direction of the Sun's meridian culmination, the region where Yang is supreme).

The annual apparent revolution of the Sun is illustrated in the Chinese year and the division of the Ecliptic into twenty-four parts (each of 15°), in each of which the Sun has a different meteorological influence, so that the famous agricultural calendar is divided into fortnightly periods, each characterised by certain climatic features.

The motion of the Moon is also shown by the division of the Ecliptic into twenty eight houses or constellations, each of which corresponds to its path during one day. The affinities between these and the particular effect each has on the Moon's influence is shown by symbols in the "lo-pan" or magician's compass, the affinities being expressed by the natural relations of the five Chinese elements. The Indian system of the twelve signs of the Zodiac does not seem to be indigenous to China, and was probably introduced by Buddhist priests, or by the Jesuit astronomers.

The next most important feature in connection with astrology, is the famous dragon of China (龍, lung[2]). The character representing this creature is one of the radicals, and both for this reason and also from its appearance we may regard it as a primitive hieroglyphic. This, together with the mystical references to the dragon in the Yih Ching, clearly shows that it

is a very ancient conception. The present form, as shown in pictures, etc., is familiar to all, and it is rather noteworthy that it is almost identical with the mythical dragon of European romance (compare the pictures of St. George and the Dragon, or the description of the Dragon in the Legend of the Island of Rhodes). Some more detailed idea of the native conception can be obtained by noticing the words written with this character lung² as the radical:—

龕 K'an¹, a shrine for an image.

龔 Kung¹, decorous.

龐 P'ang², great house, confused.

寵 Ch'ung², grace.

These are all, apparently, composite words, indicating respectively dragon-shrine, dragon-net, dragon-house, implying royalty and magnificence in each case.

Some of the words having this character as a *phonetic* seem to be composite, and so contain some idea of the attributes of this creature.

Lung² 儱, rude, unpolished (Dragon-man); 爖, to kindle a fire (Dragon-fire).

朧, rising moon, obscure (Dragon-moon); 籠, a cage, snare (Dragon-bamboo).

櫳, a pen, cage (Dragon-wood); 聾, deaf (Dragon-ear); 曨, rising sun obscured (Dragon-sun).

Lung³ 壟, mound, monopolise (Dragon-mouth); 攏, grasp (Dragon-beat); 竉, hole (Dragon-cane).

Also 襲 hsi², Dragon-clothed, hereditary.

Throughout all these there seems to be the idea of a mysterious, reserved, but royal and omnipotent power. We notice, moreover, that there is some relation to the Sun and Moon, as we have the two words 朧 and 曨, respectively meaning a rising or obscure moon and sun. Add to this the general idea that during an eclipse (日 蝕, jih⁴ shih², sun eaten away as by an insect, or 月 蝕 yüeh⁴ shih², moon eaten away) a mysterious dragon consumes the luminary, and that the imperial device of China is a dragon chasing the sun, and it is evident that there is some astronomical or solar-myth reference. It is conceivable, as far as the phenomena of eclipses are concerned, that the mysterious dragon was supposed to eat away (蝕 shih²) the sun or moon just as an insect gradually eats away a leaf with a circular cut. There are, however, other references which increase the connection with soli-lunar phenomena. The nodes of the moon's orbit (*i.e.*, the apparent points where the moon's path crosses the Ecliptic) are known to European astrologers as the Dragon's Head and Tail (written symbolically ☋ and ☊ in the almanacs); and in India there is a belief in two mysterious beasts, Rahu and Kethu, who have an intimate relation to eclipses, are regarded as two invisible planets, and are in fact the same two points, the moon's nodes. The fifth constellation of the Chinese Zodiac is also called the Dragon, but since it is only one of twelve animals it would not seem to have any special meaning here; moreover, this system of naming the parts of the Ecliptic is not much used, the titles being confined in their use almost entirely to the compound nomenclature of the sexagenary cycle. It will be remembered that the Dragon is one of the original twenty-eight constellations in the Greek catalogue of Ptolemy and Hipparchus, but this group of stars is near the Pole and cannot be regarded as having any appreciable connection with solar phenomena. The dragon occurs again as one of the two terrestrial breaths (Ch'i), or currents, named respectively the Azure Dragon 青 龍 Ch'ing Lung², having the nature of Yang, and the White Tiger 白 虎 pai hu³, having the nature of Yin.

The complete identification of the Dragon with the Yang principle appears in the first Sibylline verse of the Yih Ching, which deals with the double Chien kua, Yao (☰).

First line. 潛 龍。勿 用。
Chien lung. Wu yung. Reserved dragon. Not employed.

Second line. 龍 在 田。利 見 大 人。
Lung tsai tien. Li chien ta jen. A dragon in a field. It is an advantage to perceive a great man.

Third line. 君 子 終 日 乾 乾。夕 惕。若 厲。无 咎。
Chün-dzu chung jih chien chien. Hsi t'i jê. Li. Wu chiu. The chien figure is the time of the consummation of a superior man (or of the prince). As if lately become useful. Severe and just.

Fourth line. 或 躍 在 淵。无 咎。
Huo yüeh tsai yüan. Wu chiu. Perhaps he leaps into the abyss. No fault.

Fifth line. 飛 龍 在 天。利 見 大 人。
Fei lung tsai tien. Li chien tu ren. A flying dragon in the sky. It is an advantage to perceive a great man.

Sixth line. 亢 龍 有 悔。
K'ang lung yu hui³. The overbearing dragon has repentance.

The whole group. 見羣龍无首。吉

Chien ch'ün lung wu shou chi. Behold a multitude of dragons without a leader. Fortunate.

The oracular character of this is in no way reduced by the official commentaries, save that one line of analogy to cosmical phenomena is suggested, and a second of analogy to the ethical doctrine of Confucianism. However, it seems fairly clear that the royal, energetic and mysterious or reserved dragon typifies the active light-producing male principle. The different lines (figures in the kua, Yao) seem to imply an increasing degree of activity having diverse results. First, we have the power of the dragon as it were latent. Secondly, it becomes apparent. Thirdly, it reaches consummation. Fourthly, there is a suggestion of instability. Fifthly, an alternative of predominance is suggested; and sixthly, a moderation of energy. The whole group is regarded as a concatenation of energy without definite outcome, and it is fortunate, presumably, in that it contains boundless possibilities.

Another apparent relation of the Dragon to Solar mythology occurs in the Dragon-Boat Festival (fifth day of the Fifth Moon) and the Festival of the Dragon-God (tenth day of the Fifth Moon), which approximately coincide with the Summer Solstice. The power of Yang (Light) is of course at a maximum when the sun is at its maximum elevation (夏至 Hsia chih).

It is doubtful where one might dare suggest that the character is not a simple one, but that it consists of 立。月, and an archaic form 𢀖, the last being the actual hieroglyphic for the Beast himself, so that there is a sense of the Beast who sets up or establishes (立 li) the moon (月). This would agree very well with the notion of the dragon as the symbol of the moon's nodes.

Other mystical beasts are the following:—

麒麟 ch'i² lin², the unicorn.

鳳凰 fêng⁴ huang¹, the phœnix.

Both these seem to be associated with meteorological phenomena. The first is a quadruped with the attributes of a deer (as shown by the double use of the radical 鹿 lu⁴). The second is a bird (as shown by tradition and the radical 鳥), but the double use of the 几 feng form evidently indicates a connection with the wind, while the use of the 皇 gives a suggestion of royalty. In spite of the absence of the phonetic use of fêng in the first character, the dictionaries regard 几 (No. 10 radical) as the radical for the second character. This would seem to be open to question.

Yet another phase in the spiritual belief of China is the Tao (道) conception, which finds its principal expression in the Classic of the Virtue of the Tao (道德經) of Lao Tze (老子), and also pervades the Confucian scheme of philosophy to some extent. The essential idea seems to be a pantheistic one analogous to that of the Logos doctrine and of the Atma of Vedantism, but the Taoists appeal to its miraculous force in thaumaturgic operations.

Rules of Life.

There seems to be a strong tradition in favour of asceticism as a means of inducing psychological powers. Taoists and Buddhists agree strongly in this respect, and although Confucianism attaches prime importance to book-learning, it also would seem to favour ascetic means of acquiring knowledge. Thus Wen Wang's (文王) mystic interpretation of the Yih Kua was the fruit of his enforced seclusion in prison. There can be little doubt that a prolonged abstinence and concentration of ideas does tend to produce an ecstatic state in which visions and other apparently supernatural phenomena occur. Whether such are purely subjective or not is a matter which we are not here called upon to discuss. [It is, however, noteworthy that similiar but more awful results are produced by excessive intemperance, so that the fantastic dreams of delirium tremens, opium and bhang intoxication are frequently regarded as forms of black magic. The medieval instructions for witches in Europe contain excessive intoxication as an essential feature.]

Magical Ceremonies.

The ritual of Chinese occultism shows strong signs of a Shaman origin. The use of a drum or gong, incense, and the development of a condition of hystero-epilepsy, are all features which Chinese and Shaman cults have in common.

In the Rev. McGowan's recent book, "Side-Lights on Chinese Life," pp. 246-7, there is a description of the initiation of a priest which strongly resembles the ceremonies of the Finn sorcerers or the Bon-pa Lamas of Thibet. It reads as follows:—

"A certain weird ceremony is performed in front of the god during some dark night, when only a candle or two shows the idol surrounded by the mystery of darkness. Incantations are slowly chanted, and invocations made to the wooden image to inspire the man that stands

motionless in front of it. The tap of a drum now and again acts as a kind of bass note to the higher notes of the reciter of the vague and mystic language that is supposed to move the idol to a manifestation of its will.

"After an hour or two of this monotonous dirge and occasional tapping of the drum, which is evidently meant to quicken the decision of the god, the man who has been as silent and motionless as a statue begins to sway slightly from side to side. The taps on the drum now become more rapid and more vigorous, and ere long the wretched man becomes convulsed and falls on the ground as though he were in a fit.

"The scene is ended and the god, it is believed, has entered and taken possession of the man, and now whenever he speaks officially he does so as its inspired oracle, and his utterances are accepted as though they had been spoken by the idol itself."

Disregarding the deprecatory remarks of the reverend narrator, the following points may be noted:—

1. There is a definite ritual.

2. An environment of the most impressive character is arranged.

3. The subject remains as motionless and passive as possible.

4. The drum is beaten at intervals. This would have a hypnotic effect like the ticking of a watch or clock.

5. The ceremony is prolonged so that the nerves are continuously excited and fatigued.

6. Presently the subject begins to have automatic motion or convulsion. This is a common feature of these performances. Compare the symptoms shown by the Darweeshes in a Zikr (Lane's "Modern Egyptians") and the hysterical excitement of a revivalist meeting.

7. Finally the man recovers with a mind changed in certain respects.

It should be clearly noted that the part played by the god in this ceremony is assumed throughout by the writer of this account, and is not necessarily even supposed to be as described by him. It appears to the author more probable that the obsession is believed to be that of an inferior spirit, or it may be that actual obsession is not believed to occur but only that a state of spiritual communion with the god is produced. It is certainly very improbable that the spirit is absolutely identified with its image in the manner Mr. McGowan assumes.

TECHNICAL WORDS RELATING TO MAGIC.

念呪 nien chou⁴, to chant an invocation.
鬲 li⁴, an incense cauldron or censer.
香 hsiang¹, incense.
夢 meng⁴, vision, dream.
Ditto with 兆 (meng⁴ chao⁴), prophetic dream.
壇 t'an², altar.
Ditto with 祭 chi⁴ t'an², sacrificial altar.
禳 jang², fast and pray to avert evil.
佟 t'ung², a sorcerer.
覡 Chi⁴, a necromancer.
呼龥 Hu¹ yü⁴, to invoke.
逐鬼術 chu² kuei³ shu, exorcism (expulsion of a spirit).
畫符 hua⁴ fu², to make pictorial charms.
幻術 huan⁴ shu } spiritual magic.
妖術 yao¹ shu }
巫術 wu shu } sorcery.
怪術 kuai⁴ shu }
見神鬼 chien-shen-kuei, to see spirits.
遠見力 yuan-chien-li, clairvoyance.
預言 yü yen, prophecy.
咒訣 chou⁴ ch'ui², conjuration.
拜 pai⁴, worship.
敬 ching⁴, revere.
偶像 ou³ hsiang⁴, sympathetic image.
鬯 ch'ang⁴, sacrificial bowl (also 俎 tsu³).
鼎 ting³, sacrificial tripod.
肵 ch'i², sacrificial tray.
庵 an¹, an oratory.
占 chan¹ } to divine.
筮 shih¹ }

KENTUCKY ROCK-ASPHALT AND ITS USES.

This material, which is a siliceous sandstone containing from 5 to 25 per cent. of bitumen (maltha), is found in the upper beds of the sub-carboniferous formation, locally known as Chester sandstone. The latitude is 37° 15′, longitude 86° 15′, ten miles west from the celebrated Mammoth Cave. It is a rather fine-grained, sharp siliceous sandstone, each separate grain of which is entirely coated with bitumen to the extent of 8 to 15 per cent. The commercial product must contain at least 8 per cent. The sand is quite hard, probably as high as 7 per cent. in the scale of hardness, hence its durability as a road material. It is found in rather irregular beds or pockets, ranging in thickness from five to twenty feet, much of which can be quarried in open cut, and therefore at little expense. It is evidently the oxidised product of petroleum. It

is prepared for use on roads and streets by passing through a jaw-crusher, then through two sets of rolls eighteen inches in diameter by two feet in length, when it comes out with each grain separate and distinct, and ready to be spread cold on the prepared macadam surface to a depth of two inches, when it is sufficiently rolled, chiefly for the purpose of pressing it into the interstices of the broken stone. It is now ready for traffic; indeed this is never stopped. When freshly crushed it is of a rich, dark colour, with a slight lustre which gradually disappears as the bitumen dries and hardens.

The following may be taken as the specification for the use of the material:—"Shape and roll the roadway, then place and roll a six-inch layer of stone broken to pass through a two-and-a-half-inch ring. On this place a second layer of one-inch stone, and, before the latter is rolled, spread thoroughly and uniformly two inches of cold (uncooked) rock-asphalt. Roll thoroughly and the road is ready for traffic."

The Federal Government made a test of this material in August, 1907, upon a twenty-feet Telford road bed, which was repaired and brought to grade by means of four inches of broken stone. This course was rolled once to turn down the sharp edges and to form an even surface. No attempt was made to fill the voids, as these were to receive the rock-asphalt, which was spread to a depth of one and a half inches, care being taken to crush all the lumps and to work it into the voids of the stone without disturbing the latter. One half of the roadway was worked while the other was left for traffic. The cost of this work was 47·63 cents per square yard. The finished road surface was similar to the ordinary artificial asphalt pavement in its dark brown colour and smooth, even finish.

The Federal highway engineer in charge of this experiment says:—"The permanence of macadam construction depends largely on the nature of the binder used, and the ability of traffic to supply by attrition the material which is removed by wind and water. It was to test the rock-asphalt as a binding material that this construction was made. The pavement formed is *dustless*. There is no appreciable wear of the surface to be raised by the wind and carried away by the rain, or removed by sweeping or flushing with water. There is sufficient adhesive power in the bitumen to serve as a cement to hold the stone of the wearing-course in place, giving at once a smooth and *waterproof* surface. It is resistant to deformation under a load, yet sufficiently plastic to break the severity of the blow from the hoof of the horse, and thus in a measure avoid the harmful effects of rigid pavements on animals."

The report of inspection for the Federal Government of the above road says:—"After a searching inspection made after the fourth winter the surface is in perfect condition—as good as when first laid."

In addition to road material a mastic is made by using 75 per cent. of crushed rock-asphalt, 20 per cent. of ground limestone, and 5 per cent. of pure bitumen. This is heated to a temperature of some 250° F., and moulded into 50-lb. blocks, and finds a ready sale for waterproofing breweries, subways, etc. The cost of surfacing macadam streets and highways is ten to twenty cents per square yard higher than ordinary macadam. This material has passed the stage of experiment, and many thousands of square yards are being laid annually.

MALCOLM H. CRUMP, C.E.

THE SUGAR-PALM OF THE EAST INDIES.

The Sugar-palm (*Arenga saccharifera* of botanists) grows abundantly in all the Dutch East Indian islands, and provides the natives not only with a fermented beverage termed *sagueiro*, but with sugar, cordage for the rigging of praus and material for caulking them, and brooms for sweeping. The palm is called *pokko gamutu* by the Malays, and plenty of the trees are always found in the neighbourhood of the villages. One of the commonest daily sights in a Malay village is the bringing

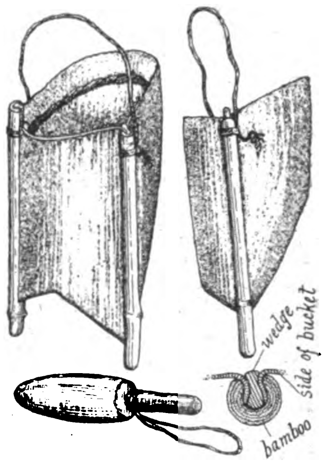
SUGAR-PALM.
(*Arenga saccharifera.*)

home, slung over the shoulder, of the large bark buckets full to the brim of sagueiro, the liquid frothing on the top and of a milk-white colour, its fluidity also resembling that of milk. The palm itself is a fine though rather rough-looking

tree, bearing huge bunches of fruit composed of large orange-coloured berries, the male inflorescence being then over, but the withered remains form similar large bunches of what at first sight look like strings of small dark purple or black berries. It is the stalk of the male inflorescence only which is tapped for the sap, and as the bunch is very heavy and also bears the weight of the sagueiro bucket, it is generally supported against the trunk by a stout prop. The palms produce fruit more or less throughout the year.

When about to tap the tree, the native usually climbs up by means of a long bamboo lashed against the trunk of the palm, just the bases of the bamboo boughs being left to form rungs or steps. He then bruises the flower-stalk with a heavy wooden pestle on all sides and from end to end, likewise swaying and twisting the bunch to loosen and disintegrate the fibres of the stem, or "make the sap flow," as the native says. Then a small nick is cut on the underside of the stem and a bucket is slung below. The tapping is done in the evening as a rule, and the sap trickles into the bucket all night, sometimes producing fifteen litres, or a little over three gallons by the time the native fetches the bucket in the early morning. During the day (say the natives) the sap practically ceases to flow, and when the bucket is taken away a leaf is tied around the wound in the stem to prevent the sap from dripping. Sometimes if there is not much sagueiro in the bucket it is left for another night on the palm, and a mass of bast from the leaf-sheaths is put over its mouth during the day to keep out sun, rain and insects—for there is always some slight drip from the buckets, and these and the jungle beneath are usually swarming with insects, all eager to lick up the sweet juice. Flies, bees and wasps are the most numerous, but many beetles and butterflies are attracted; it is in the sagueiro buckets that the large beetle with extraordinarily long forelegs (*Euchirus longimanus*) is frequently found by the natives of Ceram and Ambon, having fallen in whilst drinking the sap. One flower-stalk will often give sap for two to six months, and as one stalk fails another comes to maturity; the life of a palm being tapped regularly is said to be fifteen to twenty years. Occasionally one may observe a wasted and blackened palm which has been bled to death by tapping. The sagueiro is either drunk fresh, when it has a sweetish taste, or more often small pieces cut from the living roots of a large tree, heavy and very bitter wood of a brightish yellow colour, are put into the liquid. This makes a very refreshing drink on a hot day, and is sold very cheaply at all the wayside huts and villages. It is quite possible to become inebriated with fermented sagueiro or "palm-wine" if large potations are indulged in, though one but rarely sees a tipsy native. Nor does it produce the fighting and quarrelling that beer and spirits provoke, and these intoxicants are strictly prohibited by the Dutch Government from being supplied to the natives.

The sagueiro buckets are large—about eighteen inches deep, and, roughly, about ten in diameter—and are made of the inner part of the leaf-sheath of the ever-useful sago-palm. A long rectangular piece of sufficient length to form the two sides and the bottom of the bucket, and broad enough to make the desired diameter, is shaved down till it is about an eighth of an inch thick, and is softened by soaking in water; four slight cuts, forming a lozenge or diamond, are made at mid-length, the two ends are bent up to form the sides of the bucket, and their edges are thrust into two

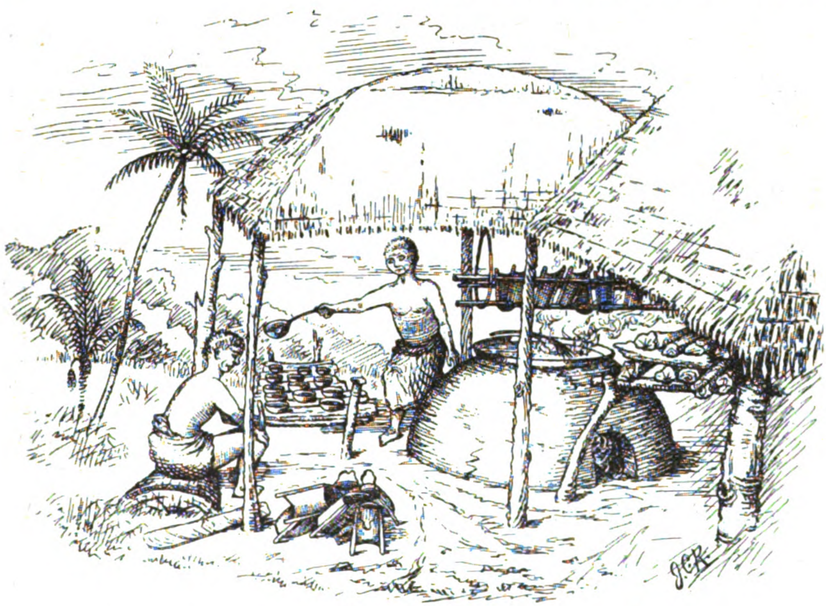


SAGUEIRO BUCKETS: MODE OF WEDGING SIDES OF BUCKET INTO BAMBOO; WOODEN PESTLE FOR BEATING FLOWER-STALKS.

pieces of bamboo, which each have a slot cut from the top to within a few inches of the bottom. Then a long wooden rod or wedge is driven down the interior of each bamboo, between the edges of the bucket-sides, as shown in the sketch. To keep the shape better, four or five rings of "gaba-gaba" or split leaf-rib of the sago-palm are often put at intervals in the interior of the bucket, and a handle of the same material completes the article, though the joints are usually caulked with "chunam," a mixture of lime and oil like putty. The inner polished and siliceous skin of the leaf-sheath forms the interior of the bucket, the exterior being left rough from the thinning-down process.

When the palm-sap is destined for sugar-making it is boiled in primitive fashion in some convenient clearing in the forest, in large, shallow iron pans set in the top of a dome-shaped clay or mud furnace. This is fired with chopped wood, a quantity of which is always piled on a rack near the furnace to dry. The empty sagueiro buckets, too, are generally suspended mouth downwards in a rack over the furnace, to clean and dry, for they cannot be left empty on the ground long without swarming with ants. A piece of the mid-rib of the sugar-palm leaf, beaten at one end to separate the fibres and make a sort of broom, is used to stir up the boiling liquor, and a rough iron ladle to test the syrup; whilst a primitive table of "gaba-gaba," and

stakes holding a supply of empty coco-nut shells in halves completes the sugar-maker's stock-in-trade. The whole apparatus is more or less protected from the weather by the usual attap-thatched open shed. The syrup is constantly stirred up with the broom to prevent burning, and from time to time a little is ladled out into a coco-nut shell to try its condition; as soon as a sample sets properly, the contents of the boiling-pan are ladled into the coco-nuts. The product forms dark-brown cakes resembling toffee in taste, and is either broken up and powdered to use like ordinary brown sugar, or melted down with a little water to make a syrup which is much eaten with sago; the broken pieces are also used as a sweetmeat.



SUGAR-BOILING.

This native manufacture of palm-sugar was still an important native industry in 1909, when Mr. F. Muir and the writer stayed some months in the Malay islands, but ordinary cane- and beet-sugar were displacing it by degrees, and doubtless before very long the making of palm-sugar by the natives will belong to past history. Yet this palm-sugar has a peculiar and nice flavour and, as the supply of firewood for boiling is free and at present unlimited, it is manufactured by the Malays at a very trifling cost.

The coarse black bast or fibre which covers the bases of the leaf-sheaths of the sugar-palm is made into cordage for rigging praus and other uses, and is known as *gamutu*. A peculiarly soft, dark snuff-brown material is scraped off the exterior of the trunk and employed both for caulking boats as already mentioned, and also for tinder. Nearly all the natives in Ceram carry a little tinder-box full of this stuff.

Wallace was, we believe, the first to notice at any length and at first-hand the manufacture of palm-wine and sugar from *Arenga saccharifera* in his "Malay Archipelago." Since he lived so many years in the fifties and sixties of the last century in these islands, they have certainly changed much. The area of actual forest on most of the islands has been greatly reduced, not so much formerly by the operations of Europeans as by the natives' habit of clearing patches of forest to enable them to grow a few bananas and vegetables and, after one crop was gathered, forsaking this ground and clearing another plot, to save the labour of properly tilling the soil. But of recent years Europeans have felled and burned off much valuable timber to make room for rubber and coco-nut and other plantations; much land in some parts has been disafforested and then deserted, and is now covered with low second-growth jungle, or, worse still, with the tall and harsh "Kusu-Kusu" grass, which is difficult to force one's way through, and cuts like knives. Ceram is at the present time almost the only island in the Dutch Indies which is practically untouched, and already forest is here being cleared for growing coco-nuts for copra. J. C. K.

HOME INDUSTRIES.

Bank Amalgamations.—Whilst banking business grows, and the aggregate of bank offices increases, the number of independent and private banks continues to diminish. The latest amalgamation is that of Messrs. Hill and Sons with Lloyd's Bank. The bank of Charles Hill and Sons was started by Mr. Charles Hill, who had been manager to Messrs. Sharpe and Sons, of West Smithfield. They failed in 1825, after which he immediately started as a banker, and carried the business on in his sole

name for three or four years, when he was joined by his sons, George Hill and John Hill. Charles Hill died in 1846, and George and John Hill carried on the business until April, 1867, when John Hill died, and John Hill junior was taken into partnership with his uncle. It is understood that all the partners will continue to be associated with the business, and the entire staff will be retained in the service of Lloyd's Bank, which will secure a valuable Smithfield connection by the amalgamation. Messrs. Hill and Sons have branches in West Smithfield, Islington, Deptford, Liverpool, Birkenhead and Romford. The number of branches of Lloyd's Bank is now raised to 601, which, in respect of the number of its offices, makes it the largest bank in the Kingdom, with the exception of the London, City and Midland, which has 680 offices. During 1910 the increase in the number of branch banks opened in England and Wales, compared with 1909, was 176, and in the United Kingdom 196. The growth of banking business in recent years is indicated by the growth of these bank offices, which in 1892 numbered less than 3,000; in 1886, 4,460; at the end of 1910, 8,279, including 123 belonging to foreign and colonial banks having offices in London.

Fire Insurance and Large Cities.—A recent discussion in the House of Commons arising out of a Bill promoted by the Newcastle Corporation disclosed very imperfect knowledge on the part of some of the speakers of fire insurance. The discussion occurred on a clause in the Bill to the effect that insurance companies having policies on property in the city shall contribute annually to the expenses of the fire brigade in proportion to the amount covered by their policies. The argument rests on the assumption that the insurance companies rather than the public benefit by the efficiency of the fire brigade, but that view can only be accepted with great reserve. Insurance companies charge what they consider adequate rates for each class of risk, and if heavy losses occur in any class or locality the rates for those risks are increased accordingly. If, on the other hand, losses are slight, competition sooner or later brings about a reduction of rates. It need hardly be added that the great insurance companies have contributed for many years past in London, Manchester, Liverpool, and other large towns.

The New Sub-Inspectors for Mines.—This new class of Sub-Inspectors of Mines is to number thirty, and the appointments will be made by the Home Secretary after a competitive examination limited to candidates nominated by him. Fifteen of the thirty are to be nominated as soon as possible, and fifteen later in the year. Of the thirty, twenty-two are to be appointed for the inspection of coal-mines and eight for the inspection of quarries. A certain number will be allotted to each of the six divisions into which the United Kingdom will ultimately be divided for the purposes of inspection, and will be selected from men working in the division. A separate examination will be held for the appointments in each division. The six divisions will be—(1) Scotland, (2) the Newcastle and Durham districts, (3) the Yorkshire division, (4) Manchester and Ireland and the Liverpool and North Wales districts, (5) the South Wales division, (6) the Midland and Southern division. The first fifteen appointments will be as follows:—Scotland, two for coal-mines; Newcastle, etc., two for coal-mines; Yorkshire, three for coal-mines; Manchester, etc., two for coal-mines, one for quarries; South Wales, two for coal-mines; Midland, etc., two for coal-mines, one for quarries. The salary of a sub-inspector is £150, rising to £200, and candidates must be between thirty and forty years of age, and have had practical experience in mines or quarries.

The Accountant Bill.—Accountants have long desired to place their profession in a position analagous to that of solicitor, doctor, and dentist, but it has been difficult to induce the chief organisations concerned to agree to a common plan. Now, however, a Bill has been drafted and read a first time in the House of Lords which is approved by the representatives of the Chartered and Incorporated Accountants. Registers are to be kept—one for England and Wales, one for Scotland, and one for Ireland—of all persons practising as professional accountants at the date of the passing of the Act. No unregistered person is to be allowed to use the title of professional accountant, or practise as such. The first persons to be registered if the Bill passes will be all existing members of the Institute of Chartered Accountants of England and Wales, the Society of Incorporated Accountants and Auditors, the three Scottish societies, and the Irish Institute, the members of certain colonial societies, and all other persons in practice as accountants in the United Kingdom at the date of the Act. After the passing of the Act no one would be registered unless he was a member of one of these bodies or had passed certain prescribed examinations. Fines and penalties would be imposed on any unregistered person who called himself a professional accountant, and there would be power to expel members, and all the machinery of the law to support the registrars and the committees. Members of the various existing bodies would still be able to call themselves "Chartered Accountants," "Incorporated Accountants," or otherwise.

Cotton Trade Statistics.—"The Cotton Spinners' and Manufacturers' Directory for 1911"—an invaluable compilation for all interested in the cotton trade—shows that the cotton industry, which has increased so largely of late years, has now become nearly stationary. During 1910 the increase in spindles was 270,606, which is the lowest since 1902, and in looms only 63, while there is actually a decrease of 11 in the number of firms, which is now 1,966. In 1904 there was a decrease in looms,

but the intervening years, up to 1910, have shown large increases, and in 1911 there has been practically no increase. The largest increase in spindles during 1911 is in the Manchester district, which on balance has added 353,090. Wigan has added 1,282 looms, Blackburn 978, Burnley only 146. Between 1905 and 1910 no less than 12,000,000 spindles and 90,000 looms were added to the industry. It is clear from these figures that the great period of expansion is at an end. It was time that it should be stopped, for the increase in productive capacity had gone ahead of the expansion of markets, large as that has been.

Small Holdings.—Parliament is about to be invited to discuss anew the comparative merits of the ownership or tenancy of small holdings. The Small Holdings Act has only been a qualified success. In 1895 there were 299,378 holdings of between one and fifty acres in England and Wales. In 1909 the number of small holdings had fallen to 288,011, and if certain necessary deductions are made, the approximate number of small holders is estimated by a well-informed writer in the *Times* at 250,000, of whom only 36,250 are proprietors. In 1909 the continuous decrease was stayed, but the net increase in 1910 was only 809. The smallness of these figures is largely owing to the absorption of many small holdings in urban districts, and to the fact that a large proportion of the new small holders were already tenants of some land. As to whether it is better to be owner or tenant, the experience of other countries—more especially France and Belgium—goes to show that the better policy is to assist small holders to purchase their holdings. Since the Small Holdings Act came into operation, only 2·3 per cent. of the applicants have expressed a wish to buy the land—the actual figures being 519 out of 22,455—but it does not follow that the applicants did not wish to buy it. They did not make application because they lacked the necessary capital for purchase and stocking. The Act does not facilitate purchase. It vests ownership in some department of the State or local authority. What may be done to help the small owner without injuring the seller is shown upon a farm in Bedfordshire—and a hundred other illustrations might be given—where a holding of some 400 acres was recently bought for its capital value at twenty-five years' purchase, and divided into eighteen small ownerships, ranging in size from 1 to 10, 20 and 40 acres. The occupiers pay annual instalments, ranging from 37*s.* to 43*s.* per acre, which also cover certain common rights. At the end of thirty-five years they will become absolute owners. But the shortest time under which a small owner can purchase under the Small Holdings Act is fifty years, and near by the farm to which reference is made above there is another bought by the county council and let to fifteen occupiers, who are paying within 3*s.* per acre in perpetuity of the price at which the holdings on the other farm were sold to occupying owners.

CORRESPONDENCE.

WHEELS, ANCIENT AND MODERN, AND THEIR MANUFACTURE.

My attention has been called to my reference to the Reid-Riekie wheel (*Journal*, April 7th, 1911, p. 532). To prevent a possible misunderstanding, may I add that the wheel there referred to is designed for steam lorries? I am informed by Mr. Riekie that the weight of springs for a motor-car wheel of this make is much less than I stated, viz., from 8 to 16 lbs., and that the free radial movement of the springs is in some cases as much as half an inch.

HENRY L. HEATHCOTE.

April 19th, 1911.

GENERAL NOTE.

SALMON-FISHING IN SIBERIA.—The most important industry of Nicolaevsk is fishing. About twelve years ago the business was of little importance, and its marvellous growth dates from that time. In 1909 the catch in the Amur River, and in the vicinity of Sakhalin Island, amounted to 90 million pounds, an increase of 18 million pounds over 1908. There are three varieties of salmon at these fisheries, namely, Gorbusha, summer, and autumn, the most valuable being the last named. Up to 1907 salmon caviar was considered valueless and was thrown away, but it has since come into use. It sells for three-halfpence in the district where obtained. The amount of caviar obtained from 1,000 Gorbusha salmon is 90 pounds, from the same number of summer salmon 126 pounds, and from 1,000 autumn salmon 144 pounds. About two-thirds of the annual catch of salmon is sold to Japanese fishermen from Hokodate, who prepare and ship them to Japan. The remainder is either smoked or salted, and packed in barrels for shipment to western Siberia and European Russia. There are two refrigerating plants near Nicolaevsk, and large quantities of fish have been frozen and shipped to Hamburg, but the enterprise has not been a success owing to lack of capital. In 1909, however, a British firm sent a refrigerating ship and took frozen fish to Europe, and it is understood that the enterprise was successful. Fishing in the Amur Province is almost entirely in the hands of the Cossacks, who own the lands along the river fronts.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

APRIL 26.—NOEL HEATON, B.Sc., F.C.S., "The Production and Identification of Imitation and Artificial Gems." Principal HENRY A. MIERS, M.A., D.Sc., F.R.S., will preside.

MAY 3.—A. W. GATTIE, "London Transport." JAMES SWINBURNE, M.Inst.C.E., F.R.S., will preside.

MAY 10.—HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

MAY 17.—Professor RAOUL PICTET, "Les Basses Températures."

MAY 24.—FRANK M. ANDREWS, "Architecture in America." Sir ASTON WEBB, C.B., R.A., F.R.I.B.A., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

APRIL 27.—SIR THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India." Sir ARUNDEL T. ARUNDEL, K.C.S.I., will preside.

MAY 25.—W. R. H. MERK, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 o'clock:—

MAY 9.—F. WILLIAMS TAYLOR, "Canada and Canadian Banking."

CANTOR LECTURES.

Monday Evenings, at 8 o'clock:—

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

May 1, 8, 15, 22.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 24...Victoria Institute, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Sir David Gill, "The Sidereal Universe."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. 1. Mr. Haydn T. Harrison, "The Ratio of Light to Illumination." 2. Mr. P. J. Waldram, "Some Notes on the Effect of Wall-papers upon the Illumination of Interiors."

Sanitary Engineers, 120, Victoria-street, S.W., 8 p.m. Mr. G. W. Chilvers, (a) "The Mechanics of Municipal and Sanitary Engineering"; (b) "Refuse Destructors and Power Plant."

Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. W. R. Baldwin-Wiseman's paper, "The Conservation of our National Water Resources," and on Mr. W. Vaux Graham's and Mr. H. F. Bidder's paper, "Judicial and Parliamentary Decisions with Regard to Rights in Underground Water since 1907."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Professor Beresford Pite, "Alberti and Bramante: Architecture a Profession or an Art in the Cinque Cento?"

TUESDAY, APRIL 25...Statistical, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. E. C. Snow, "The Application of the Method of Multiple Correlation to the Estimation of Post-Censal Populations."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. J. E. C. Bodley, "Cardinal Manning."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Annual General Meeting.

Zoological, Regent's-park, N.W., 8.30 p.m. 1. Mr. D. Seth-Smith, (a) "Penguins in Moult"; (b) "Wild Swainson's Lorikeets." 2. Dr. R. T. Leiper, "Some new Parasitic Nematodes from Tropical Africa." 3. Dr. Cuthbert Christy, "On a Collection of Antelope and other Skins from the Chagwe Forests, Uganda." 4. Dr. William Nicoll, "On Three new Trematodes from Reptiles."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. C. Bright, "Imperial Telegraphs."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Dr. W. Rosenhain, "Steel." (Lecture II.)

WEDNESDAY, APRIL 26...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Noel Heaton, "The Production and Identification of Imitation and Artificial Gems."

Geological, Burlington House, W., 8 p.m. 1. Mr. Arthur Wade, "The Llandovery and Associated Rocks of North-Eastern Montgomeryshire." 2. Dr. J. D. Falconer, "The Geology of Northern Nigeria."

Chartered Institute of Secretaries, Great Hall, River Plate House, Finsbury-circus, E.C., 5.30 p.m. Mr. A. J. M. Brice, "The Law as to Misrepresentation."

United Service Institution, Whitehall, S.W., 3 p.m. Mr. P. Bramley, "The Indian Waterway from a Strategical Point of View."

Royal Society of Literature, 20, Hanover-square, W., 5 p.m. 1. Mr. F. R. Harris, "Lady Betty Molyneux." 2. Dr. W. E. A. Axon, "A Fourteenth Century French Fragment of Sydrach."

Mining and Metallurgy, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m.

THURSDAY, APRIL 27...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Sir Thomas Henry Holland, "The Trend of Mineral Development in India."

Royal Institution, Albemarle-street, W., 3 p.m. (Tyndall Lecture.) Professor R. W. Wood, "The Optical Properties of Metallic Vapours." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. Francis Ward, "Phases of Fish Life, and How to Record Them."

Optical, at the Chemical Society's Rooms, Burlington House, W., 8 p.m. Mr. H. S. Ryland, "The Forms and Errors of Visual Lenses."

NOTICES.

NEXT WEEK.

MONDAY, MAY 1ST, 8 p.m. (Cantor Lecture.) ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." (Lecture I.)

WEDNESDAY, MAY 3RD, 8 p.m. (Ordinary Meeting.) A. W. GATTIE, "Improvements in the Transport and Distribution of Goods in London." JAMES SWINBURNE, M.Inst.C.E., F.R.S., will preside.

INDIAN SECTION.

THURSDAY AFTERNOON, APRIL 27TH, Sir ARUNDEL T. ARUNDEL, K.C.S.I., in the chair. A paper on "The Trend of Mineral Development in India" was read by Professor Sir THOMAS HENRY HOLLAND, K.C.I.E., D.Sc., F.R.S.

The paper and discussion will be published in a subsequent number of the *Journal.*

CONVERSAZIONE.

The Society's Conversazione will be held, by permission of the Trustees of the British Museum, in the Galleries of the Natural History Museum, South Kensington, on Tuesday Evening, May 30th, from 9 p.m. to 12.

The Reception, by Sir JOHN CAMERON LAMB, C.B., C.M.G., Chairman, and the other Members of the Council, will be held in the Central Hall from 9 to 10 p.m.

A Selection of Music will be performed by the Band of H.M. Royal Artillery, in the Central Hall, commencing at 9 o'clock.

A Vocal and Instrumental Concert will be given in the Fish Gallery and a Miscellaneous Entertainment in the Shell Gallery, under the direction of Mr. PATRICK KIRWAN, commencing at 9.30 p.m.

The following portions of the Museum will be open:—

The Central Hall, containing cases of specimens illustrating Mimicry; Adaptation of Colour to surrounding conditions; Protective Resemblance; etc. Also specimens illustrating the Food of Fishes, and the Life History of the Eel (East of staircase).

The North Hall, containing the collection of Domesticated Animals.

The Bird Gallery, containing groups of British Birds and Nests; and in the Pavilion, at the West end, an exhibition of the Land and Fresh-water Vertebrate Animals of the British Isles.

The Fish Gallery, containing the Great Basking Shark, the grotesque Deep-sea Fishes (case 44), the Tunny (case 38), the Tarpon and Angler-fish (case 27), and the Lemon-Sole (case 30), etc.

The Shell Gallery, including a life-size model of a Giant Squid (Newfoundland), and of a Giant Octopus (California).

The East and West Corridors on the First Floor, containing the Okapi, African Antelopes, and Giraffes.

Light Refreshments will be supplied at Buffets in the North and South Corridors on the First Floor of the Museum.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. (These cards will be issued shortly.) In addition to this, a limited number of Tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5*s.* each, if purchased before the day of the Conversazione. On that day the price will be raised to 7*s.* 6*d.*

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the Offices of the

Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

It will greatly facilitate the arrangements if members requiring additional tickets will apply for them at as early a date as convenient.

The Council reserve the right of stopping the sale of tickets or of raising the price, if it is found necessary, in order to restrict the number of visitors within reasonable limits.

Further particulars as to the musical and other arrangements will be given in the Programmes, which will be distributed on the evening.

PROCEEDINGS OF THE SOCIETY.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 26th, 1911; Principal Henry A. Miers, M.A., D.Sc., F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Boyd, Miss Emma S., 18, King's-road, Southsea, Hants.

Croll, George, Camden House, Chislehurst, Kent.

Holland, William W., Ph.D., Johns Hopkins University, Baltimore, Maryland, U.S.A.

Holman, Arthur, Ishapore, Bengal, India.

Howat, William Frederick, M.D., Hammond, Indiana, U.S.A.

Sanguinetti, Vivian, c/o Dr. H. H. Sanguinetti, 19, Camden House-road, Kensington, W.

Triggs, Bernard, c/o Messrs. Cox & Co., 16, Charing-Cross, S.W., and Royal Bombay Yacht Club, Bombay, India.

Wood, Casey A., D.C.L., M.D., Suite 1208, Chicago Savings Bank Building, State and Madison-streets, Chicago, Illinois, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Browell, Colonel Edward Thomas (late R.A.), Merrow House, near Guildford, Surrey.

Cotman, Henry William, The Quadrant, St. Ives Hunts, and the Arts Club, 40, Dover-street, W.

Evans, J. Howell, M.A., M.B., M.Ch. (Oxon.), F.R.C.S., 25, Berkeley-square, W.

Graham, W. L., 33, Bowerdean-street, Fulham, S.W., and Bon Accord Sheet Metal Works, Townmead-road, Fulham, S.W.

Hudson, Lieut.-Colonel Sir William Brereton, K.C.I.E., Fairholme, West Kensington, W.

Khan, Khur Shaid Ali, c/o Messrs. Henry Adams and Son, 60, Queen Victoria-street, E.C.

Provis, Charles Herbert, Highfield, Mutley-road, Plymouth.

The paper read was—

THE PRODUCTION AND IDENTIFICATION OF ARTIFICIAL GEMS.

By Noel Heaton, B.Sc., F.C.S.

In order to make the object and scope of this paper clear, I may say at once that I have not anything original to bring before you, or anything that is particularly new to those who have followed recent work on the artificial production of precious minerals. My object is more to review the whole subject in a comprehensive manner from its scientific and economic aspect, and particularly to bring the records of this Society up to date, as it were, by describing such advances as have been made since the subject of precious stones was last discussed in this room.

During recent years the production of artificial gems on a commercial scale has become an accomplished fact, and a great many misconceptions and misleading statements have been made as to the relation which these productions bear to natural products on the one hand and imitation gems on the other. It may therefore be of some use to make the matter clear by describing as fully as circumstances permit what has been done in this direction and what has not been done; what is practicable and what is impracticable in the present state of our knowledge.

I suppose there are few subjects of interest from so many points of view as that of precious stones. The beauty and rarity of fine specimens has from time immemorial rendered them the most treasured of possessions. With the romance that surrounds this aspect of the question we have nothing whatever to do to-night, except to bear in mind that on account of their great value men have for centuries strained their ingenuity to solve the mystery that surrounds the origin of such stones, and amass wealth by producing them at will instead of by the laborious and highly speculative process of digging for them in the earth.

Until the development of modern science and accurate methods of investigation, this problem

resisted all attempts at solution, and it is, in fact, only within the last few years that the artificial production of any species of gem on a commercial scale has become practicable.

Of course, one can cut the Gordian knot by preparing a colourable imitation of the real thing, but that is quite another matter, and I want to make it quite clear, at this point, that I propose to limit the term "artificial" to such productions as possess the same chemical composition and physical constants as the natural stones, differing from them only in minute details consequent upon their being produced in the laboratory instead of being dug out of the earth; all other makeshifts being properly described as "imitations." The production of *imitation* gems is by no means a modern invention, as is doubtless well known to you. To go no further back than the time of the Roman Empire, the master glassmakers of the dawn of our era, whose skill and knowledge of glassmaking one appreciates more highly the more one investigates the industrial life of those times, were able to imitate almost any precious stone exactly, as far as outward appearance went, in coloured glass—and not only the transparent gems, but the structure of such semi-precious stones as agate, cornelian, lapis, and porphyry. It would be quite out of place to devote any time to-night to this historical aspect of imitation gems, but I cannot refrain from alluding to the remarkable examples of such imitations found by Mr. Woolley at Karanòg,* from which it is difficult to resist the conclusion that in quite early times Nubia was the centre of this industry. To judge by the stories one reads about jewels in those times—stories of the Emperor Comnenus, for example—one suspects that the glassmakers turned their skill in this direction to some account and considerable profit on behalf of an ignorant and somewhat credulous aristocracy; for in those days, and, in fact, until quite recently, not only was the nomenclature of gems very vague, but methods of identification were chiefly remarkable for their non-existence.

The chief criterion of a precious stone was its colour, so much so that throughout mediaeval times blue glass was known as sapphire and green glass as beryl, etc., giving rise to the legend that in the time of Queen Elizabeth windows were glazed with sheets of beryl.* As the tendency still lingers to regard all red stones as rubies and green as emeralds, and so on, I would like to make it clear at this point that colour is really quite an accidental property of precious stones: the substance of which nearly every species of transparent gem is essentially composed is colourless, and the colour is really produced by minute proportions of impurity.

This being the case, we find that on the one hand the same species of gem may exist in a large variety of colours, and on the other hand that a colour characteristically associated with one gem may often be found in another having essentially different composition and properties. Owing to this confusion it was very difficult to draw the line between a genuine and imitation stone until the various species of gem stone were accurately defined and their names clearly associated with particular composition and properties, the

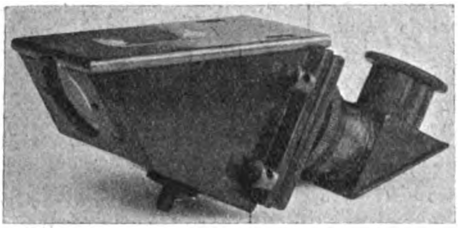
* "Karanòg," by C. L. Woolley and D. Randall. MacIver: Philadelphia Museum, 1910.

* This is quoted in Hollingshed. We read in Theophilus (II., Cap. xii.) of "tabulas saphiri pretiosas ac satis utiles in fenestris." In a previous paper (*Journal*, March 15th, 1907) I have shown how the name jet was applied indifferently to

determination of which forms, at the present time, a means of distinguishing one from another, and also of deciding whether an alleged gem is genuine or imitation with ease and certainty.

The scientific examination and identification of gems in this manner is a matter of the greatest

FIG. 1.



THE HERBERT SMITH REFRACTOMETER.

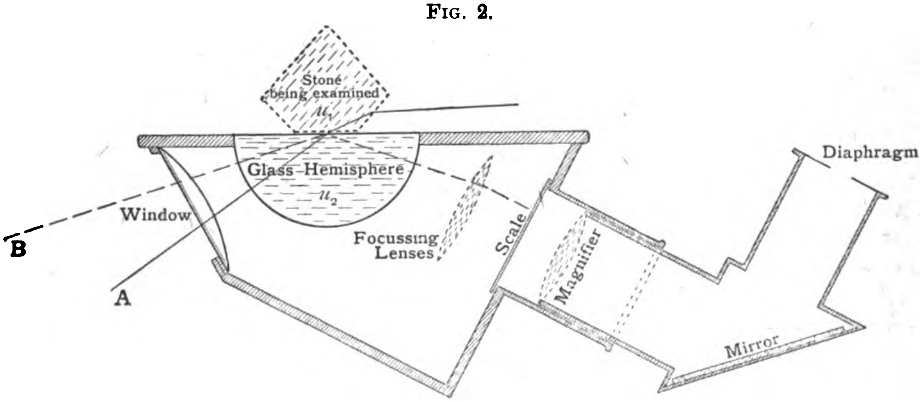
interest, but it would take far too much time to discuss it in detail, and it is quite unnecessary to do so, because it has already been brought before the Society most exhaustively by our chairman, Dr. Miers.* I propose, therefore, merely to remind you of the main points by means of the accompanying summary (Table I.).

In order to bring this matter up to date in the records of the Society, however, I must refer briefly to one or two particulars in which advance has been made since the time of these lectures.

The most important properties of a precious stone are those depending upon its refractive powers. Until recently the accurate determination of the refractive index of a stone was a matter involving the use of complicated and expensive instruments, and a matter for the skilled mineralogist rather than the practical jeweller. It is true that at the time Dr. Miers published his lectures there existed an instrument known as the Reflectometer, but the determination of the refractive index with this was a matter of some difficulty even in skilled hands, and its value for commercial purposes was very small. Since that time, however, thanks to the ingenuity of Dr. Herbert Smith, this instrument has been improved out of all recognition, and in its place we have the Herbert Smith Refractometer (Fig. 1), by means of which anyone of normal common-sense can determine the refractive index of a stone in a few seconds without even removing it from its setting, and which, with a little practice, will also enable one to determine with similar ease the amount and kind of double refraction and the degree of dispersion.

As will be seen from the diagram (Fig. 2), the main principle of the instrument is the same as that of the reflectometer, the refractive index being measured against a standard of highly refracting glass by means of the angle of total reflection, which of course diminishes, the nearer the index of the stone approaches that of the standard. It is, however, in the details of construction that such a marked advance has been made, and it is these details which make all the difference in practical work. To use this instrument all that has to be done is to place the stone under examination in optical contact with the flat surface of the dense glass, and arrange it so that a good light (preferably monochromatic) enters the instrument through the lower lenticular opening, when the refractive index is read off directly on a scale, without calculation.*

FIG. 2.



CONSTRUCTION OF THE HERBERT SMITH REFRACTOMETER.

Some little advance has also been made in the construction of the Dichroscope for determining pleochroism. As will be seen from the

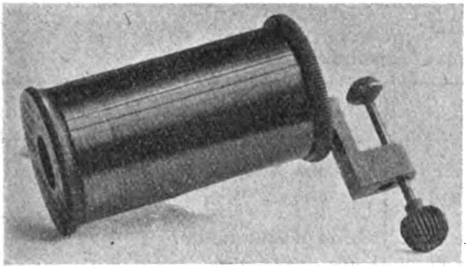
* Cantor Lectures on Precious Stones, April, 1896.

* It is impossible here to give any detailed account of the construction and use of this instrument. Full particulars will be found in "The Herbert Smith Refractometer," published by J. H. Steward, 406, Strand.

illustration (Fig. 3), the instrument in use to-day is provided with a revolving holder tipped with wax, to which the stone is readily fixed, leaving both hands free. A detail, but again it is such details that count in practice.

Taking the properties of precious stones as a whole, the great point about them is the remarkable combination of qualities; it is not so much that they have optical properties which make them extraordinarily beautiful, or that they have remarkable hardness and durability, but they have *both*, and it is the impossibility of reproducing this combination in any other material that renders the detection of imitations a matter of ease in the hands of anyone familiar with the facts.

Fig. 3.



The Dichroscope.

Of course, glass is the obvious material to use in the production of imitation gems, and, as I have indicated, it has been so used from time immemorial. And, in later times, while science was equipping the expert in precious stones with the means of identifying them with certainty, the maker of imitations was also invoking its aid in the production of more successful imitations.

In modern times the manufacture of imitation gems on scientific lines was introduced by Strasser in Vienna; hence the name "strass," although "paste" is the more commonly used term.

The finest of such modern paste bears little relation to the clumsy imitations of early times; the glass is specially prepared in order to combine, as far as possible, the necessary optical qualities with a fair amount of durability. It is well known that by using lead instead of lime as the basic constituent, the refractive index and dispersive power of glass are much increased, and by replacing the alkaline constituent by thallium oxide in the same manner the refractive index may be raised as high as 1·96 and the dispersion to 0·049.* By adjusting the composition in this way, and preparing the glass with the greatest regard to the purity of the materials, manipulating it, moreover, in a similar elaborate manner to that employed in the production of glass for optical instruments, in order to secure the utmost freedom from striation and inclusions, it is possible to imitate any precious stone accurately, as far as outward appearance is concerned.

The trouble is, however, that with glass the more you increase its refractive power in this way the softer and less durable it becomes, until you find that the very "dense" flint used for the refractometer, having a refractive index of 1·8049, is so soft that it has to be handled with great care to avoid scratches, and so little resistant to decay that in a comparatively short time the exposed

TABLE II.

Identification of Imitation Gems.

Paste.	Stones.
Index of Refraction rarely exceeds 1·65.	Index of Refraction ranging up to 2·4.
Single Refracting, or false double Refracting owing to strain.	Double Refracting, with exception of Diamond, Garnet, and Spinel.
Never Pleochroic.	Often strongly Pleochroic when coloured.
Hardness always below 7.	Hardness 7 or over (with a few exceptions).
Specific Gravity usually above 4.	Specific Gravity usually below 4.
Thermal Conductivity low.	Thermal Conductivity comparatively high.
Opaque to X-Rays.	Translucent or transparent to X-Rays.
Generally show spherical bubbles and curved striae.	Frequently show lamination or inclusions.

* These are the constants given for the Jena glass, No. S. 57: the specific gravity is 6·33. Refractive index of diamond is 2·4, and dispersion 0·057.

surface becomes corroded, which is the one weak point of this instrument. It is true that this softness may be counteracted to some extent by further adjustment of the composition, adding a proportion of alumina and zinc, and by careful thermal treatment of the finished stone in some such manner as that originally introduced by Bastie, in which the glass is case-hardened by plunging whilst hot into a bath of oil. In some of the best modern paste I have found a refractive index of over 1·6 combined with a hardness close on that of quartz, but this is the absolute limit, and it is not possible in any way to obtain a paste that cannot be scratched with a hardened steel point. Paste can also be readily identified by means of the scientific tests, as indicated in Table II.

The most important point to remember about paste, however, is its lack of durability; it is not only too soft to stand much wear, but its composition is so unstable that it rapidly deteriorates and loses its brilliancy on exposure. You will see, therefore, that although there is a certain legitimate scope for such paste imitations they are very unsatisfactory substitutes for the genuine article. This being the case, as scientific knowledge has advanced, attention has been more and more concentrated on the problem of producing by artificial means the actual minerals found in nature, and thus obtaining what I have defined as artificial in contradistinction to imitation jewels, having both the beauty and durability of the natural article without the objectional concomitant of enormous cost.

TABLE III.

COMPOSITION OF THE PRINCIPAL PRECIOUS STONES.

	SPECIES.	VARIETY.	COMPOSITION.
ELEMENT	Diamond	—	Carbon.
OXIDES	Corundum	Ruby. Sapphire Oriental Amethyst, etc.	Oxide of Aluminium.
	Quartz	Crystal. Amethyst Cairngorm, etc.	Silica.
ALUMINATES	Spinel	Balas Ruby, etc.	Magnesium Aluminate.
	Chrysoberyl	Cymophane Alexandrite	Beryllium Aluminate.
SILICATES	Beryl	Emerald Aquamarine	Beryllium Aluminium Silicate.
	Garnet	Hessonite	Calcium Aluminium Silicate.
		Pyrope	Magnesium Aluminium Silicate.
		Almandine	Iron Aluminium Silicate.
		Demantoid, etc.	Calcium Iron Silicate.
	Olivene	(Peridot)	Magnesium Iron Silicate.
	Sphene	—	Calcium Titanium Silicate.
	Spodumene	(Kunzite)	Lithium Aluminium Silicate.
	Topaz	—	Aluminium Fluo-Silicate.
	Tourmaline	—	Complex Alkali-Lime-Alumina Silicate.
	Zircon	Jargoon Hyacinth	Zirconium Silicate.
	Turquoise	—	Hydrous Aluminium Phosphate.
	Opal	—	Hydrous Silica.
	Pearl	—	Calcium Carbonate.

The first point to be considered in attacking this problem is the composition of the stone, as it is obvious that, other things being equal, the possibilities of success are greater with one of simple than one of comparatively complicated composition. One also has to consider, however, the economic aspect—it is not much use devoting time and ingenuity to the production of an artificial stone when the natural one is so common that the cost of the two would be practically identical.

Taking these two points in conjunction, and

confining our attention for the moment to the transparent stones as summarised in Table III., the diamond appears to offer the most promising field for attack and corundum comes next, and we find that the main attempts at artificial production centre round these species. From the point of view of composition alone, quartz is the most simple, but it is so common in nature as to render its artificial production scarcely worth while. The aluminate group offers some attraction, but the artificial production of crystalline silicates on a large scale is a very difficult problem, and, with the exception of the emerald, the stones comprised in this group are so freely distributed in nature as to render their artificial production a matter of academic rather than industrial interest.

It is unnecessary to discuss at any length the artificial production of the diamond*—the problem has been attacked by numerous scientists, and was solved by Moissan some years ago. Some fifteen years ago, on the occasion of a visit to Paris, I had the privilege of witnessing the production of his diamonds, prepared, as all the world knows, by saturating iron with carbon at the temperature of the electric arc and plunging the molten mass into cold water. The mass of iron is then dissolved in acid and the residue subjected to a laborious process of extraction, the diamonds being picked out by aid of the microscope. The largest diamond that has been produced in this way is barely visible to the naked eye, however, and when I say that the problem of their production has been solved, I mean from the scientific point of view.

The artificial production of the diamond is, in fact, far more complicated than it appears at first sight. If it were only a matter of obtaining the necessary high temperature to fuse the carbon to obtain it in the crystalline condition it would be simple—such high temperatures are readily obtained nowadays by means of the electric furnace and the oxy-acetylene flame—but carbon is one of those substances which pass direct from the solid to the gaseous state under ordinary atmospheric conditions, and only assumes the liquid condition under enormous pressure. The combination of high temperature and enormous pressure can be obtained momentarily by Moissan's ingenious process, but to obtain crystals of any size it is necessary to conduct the operation on a very large scale and to maintain the combined temperature and pressure for a sufficient length of time to allow the liquid carbon to separate out from its matrix; moreover, the entire operation must be conducted out of contact with air, for carbon rapidly combines with oxygen at high temperatures.

Commercially, we are as far from being able to produce artificial diamonds as in the days of the alchemists. It is, perhaps, a bold thing to say that no such thing as an artificial diamond will ever be placed on the market, but one can safely assert that so far as our knowledge stands at present it is impracticable. In saying this, I am quite aware that statements as to the commercial production of synthetic diamonds being an accomplished fact have quite recently appeared broadcast in the public press, but those who are responsible for such statements are, shall we say, under a misapprehension as to the meaning generally conveyed by the term "synthetic," and are unable to follow the distinction I have drawn between an artificial gem and an imitation.

To pass on to corundum, the problem of its artificial production is very much simplified by the fact that its composition is oxide of aluminium, and alumina—which is, therefore, its amorphous equivalent—fuses to a liquid under ordinary atmospheric pressure at a temperature somewhere about 2,000° C. (the exact point has not as yet been determined), and being the only stable oxide of a strongly basic metal, it can be heated in air without any change.

The chief problem to be faced, therefore, is that of attaining the necessary temperature, and it is not surprising that crystalline alumina was produced as a scientific curiosity as far back as the commencement of the nineteenth century. It is at this time that we first begin to hear of the oxy-hydrogen blowpipe (or the gas blowpipe as it was then called), and in a book published in 1819,* describing various experiments with this new apparatus, we read that "two rubies were placed upon charcoal and exposed to the flame of the gas blowpipe . . . after suffering it to become cold . . . the two rubies were melted into one bead." This hint does not appear to have been followed up for some considerable time, however, and the earlier experimenters in the production of artificial gems worked in another direction; they were unable to obtain products of commercial utility, because although they succeeded in obtaining crystalline alumina, it was produced

* A complete account is given in "Diamonds," by Sir William Crookes (Harper's Library of Living Thought).

* "The Gas Blowpipe," by Dr. E. D. Clarke.

under conditions which resulted in the formation of a mass of small crystals, almost microscopic in size. Moreover, the form of these crystals was that of the hexagonal plate which is the fundamental form of corundum, and such a form would be useless for cutting even when of considerable area, owing to its thinness. Thus Gaudin, who appears to have been one of the first to attain any success in this direction, obtained a mass of such crystals by fusing alum and potassium sulphate in a closed crucible. Ebelman obtained similar results by fusing alumina with borax, and later Deville and Caron used aluminium fluoride and boric acid. All these attempts yielded similar results, as in each case fusion was obtained by the aid of a substance melting at a lower temperature which acted as a solvent. Consequently the alumina crystallised out in much the same manner as a salt crystallises from a saturated solution, and to obtain sufficiently large crystals to be of practical use it would be necessary to conduct the experiment on a very large scale, and subject the fused mass to very slow and carefully-regulated cooling.

In 1877 Fremy and Feil attempted to get over this difficulty by using lead oxide as the flux and employing a crucible composed of highly-acid clay. On heating up the mixture in such a crucible the lead oxide melts and combines with the alumina to form lead aluminate, and on further heating this reacts with the silica of the fire-clay, forming lead silicate and setting free the alumina, which crystallises out. But although very much larger crystals were obtained by this ingenious process they had the same form, and were too thin for industrial employment.*

Some time earlier than this, however, we hear of the oxy-hydrogen blowpipe again, for Gaudin had noticed (as Clarke did in 1819) that by introducing alumina into the flame of an oxy-hydrogen blowpipe he could obtain globules of fused alumina similar to the borax beads one makes in the ordinary blowpipe. Gaudin appears to have taken it for granted that these beads were amorphous—that is, an alumina glass—and it was not realised until many years later that they were really identical in all their properties with natural crystalline corundum. When this was realised, the commercial production of corundum became only a matter of detail.

Having obtained this further point, the idea immediately suggests itself of converting small and useless stones into valuable gems by fusing them together into one, and, as a matter of fact, "reconstructed rubies"—as stones produced by this method are now generally called—made in this manner were the first artificial gems to be prepared on a commercial scale. These were introduced some quarter of a century ago under the name of "Geneva rubies," and were offered as, and realised the price of, natural stones, until the method of their production became apparent.

It will, of course, be well understood that the experiments I have briefly indicated towards the artificial production of corundum had as their immediate objective the formation of ruby, that being by far the most valuable variety. It had long been known that the colour of the ruby was due to a trace of chromium, and by adding a small proportion of potassium or ammonium chromate to their mixture, Fremy and Feil reproduced accurately the colour of the ruby in their crystalline flakes.

The process of producing reconstructed rubies by means of the oxy-hydrogen blowpipe is, roughly, as follows:—The residue from cutting rubies and small worthless stones is broken into coarse sand, a small quantity of which is placed on the centre of a disc of platinum; this is then carefully brought to the fusion point, care being taken at this stage not to raise the temperature to such an extent as to melt the platinum support. As soon as this mass is fused it serves to protect the platinum, and the reconstructed ruby can be built up on it by adding the fragments of ruby one at a time by means of small platinum forceps. These pieces have to be dropped on with great care in order to secure incorporation with the mass and prevent as far as possible the formation of air bubbles. It will be readily understood that this process is a tedious and laborious one, and, in fact, the formation of masses of sufficient size to yield large stones on cutting is a matter of such difficulty that the cost of production is very high.

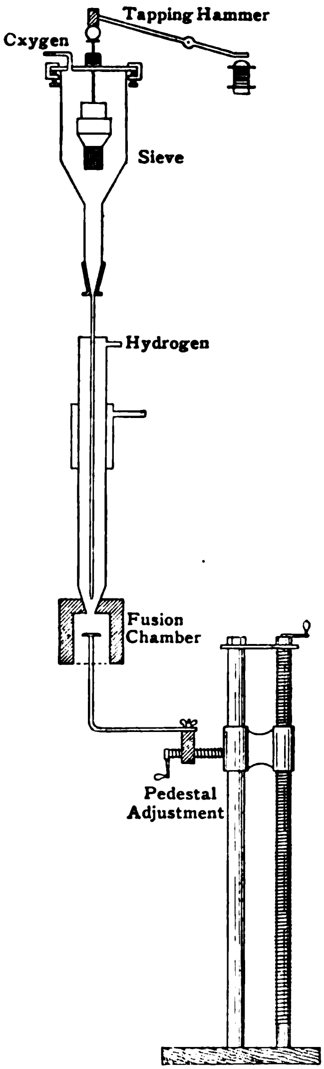
Just about seven years ago, however, Verneuil* overcame this restriction when he hit on the extremely ingenious idea of introducing the raw material through the blowpipe, and thus placing it on the support automatically. The diagram (Fig. 4) shows the principle of his apparatus. The blowpipe is arranged vertically over a small insulated chamber containing the

* For a full account of the history of these earlier attempts, see "La Synthèse du Rubis," by F. Fremy, 1891.

* "Mémoire sur la reproduction artificielle du rubis par fusion," M. A. Verneuil, *Annales de Chimie et de Physique*, Sept., 1904.

support on which the mass is to be built up. The oxygen tube communicates at its upper extremity with a funnel-shaped hopper, in which is suspended a small sieve filled with the raw material, which is rhythmically shaken by means of a small hammer actuated by an electro-magnet or cam. Each time the hammer taps the support of the sieve, causing it to

FIG. 4.

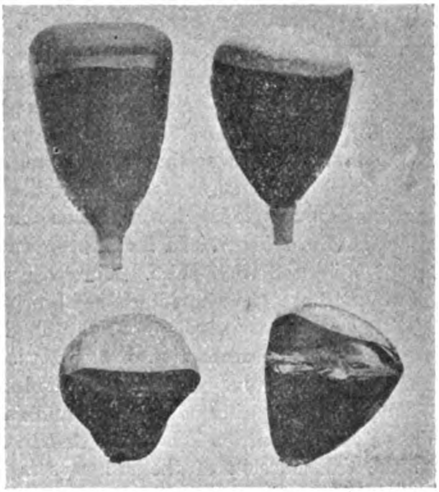


PRINCIPLE OF VERNEUIL'S APPARATUS FOR PRODUCTION OF ARTIFICIAL CORUNDUM.

vibrate, a small quantity of the powder falls through into the tube below, and, carried along by the gas, passes out at its lower extremity into the zone of flame, where it is immediately raised to the fusion point, and falls as a melted globule on to the support below.

As seen in the diagram, this support is arranged with a screw adjustment, so that as the mass of corundum is gradually built up by the constant addition of fresh globules the surface can be kept at a constant level, and the portion already formed removed from the zone of heating so as to allow it to stiffen. When the apparatus is first started the blowpipe is adjusted so as to give a comparatively cool flame, and the powder is admitted slowly. By this means a small "stalk" is formed, which insulates the mass from the support and prevents the fusion of the latter. When this has been formed the full pressure of the blowpipe is put on and the rate of admission increased, with the consequent formation of a "boule," as it is termed, having the shape of a pear as illustrated in Fig. 5.

FIG. 5.



"BOULES" OF ARTIFICIAL CORUNDUM.

With this apparatus a boule weighing some twenty to thirty carats, and capable of yielding two cut stones of about six carats each, can be prepared in about half an hour almost automatically, a single operator being able to control several machines. The boules, on cooling, very often split in half in the direction of their growth, as in the lower example seen in Fig. 5, and this is a convenience rather than otherwise, as the resulting shape can be cut to greater advantage.

In the first instance reconstructed rubies were made in this way after the manner introduced by Gaudin, the material fed into the blowpipe being pulverised rubies and chips, and this method is still employed by some workers. But more commonly nowadays the corundum is produced direct from amorphous alumina by using pure ammonium alum as the raw material. On reaching the flame this decomposes, the

ammonia and sulphuric acid volatilising, leaving the alumina. Stones made by this process are generally known as "synthetic," as distinct from "reconstructed," although, of course, to be pedantic, the process is one of decomposition rather than synthesis.

The "synthetic" corundum produced in this way, if pure ammonium alum is used, is, of course, colourless, and can be used as artificial white sapphire. If a small proportion of chrome alum is added, the resulting stones are rubies, and other colours may be produced in the same way. For a long time all attempts to reproduce the fine blue of the sapphire failed, because, following the apparent analogy of silicates, cobalt was invariably employed as the colouring agent. This, however, does not readily form an aluminate in the same way that it does a silicate, and, in consequence, it is impossible to produce a satisfactory colouration in the corundum by its means; it is possible to get the cobalt in a state of combination by adding a large proportion of magnesia to the alumina, but then the product formed is not a crystalline alumina but magnesium aluminate, and its properties are fundamentally different. Its refractive index is lower, its refraction single, and its hardness lower. In fact, the result is blue spinel instead of sapphire. Moreover, such blue stones have the characteristic absorption of cobalt, and appear purple in a light that does not contain a large proportion of blue rays.

In 1908 Paris attempted to avoid this latter difficulty by preparing a calcium aluminate coloured with cobalt, as it is found that in this case the transmission of the red rays is less pronounced. But the calcium aluminate so formed is not crystalline at all, but amorphous. A year or so ago, however, the problem of producing synthetic sapphire was finally solved by the use of titanium oxide, a very unexpected result, considering the chemical position of this element. With this last advance the artificial production of the corundum gem-stone may be considered to be completely solved, and cut stones can now be obtained in every variety of colour, from pure white to ruby and sapphire, at prices ranging from four to ten shillings a carat, according to colour, quality and size.

Whatever may be their economic importance, a very much debated question, there can be no doubt as to the scientific interest of this group of artificial gems. In the first place it is a matter of some interest that a mass of fused material formed in this way should not only be crystalline but possess all the characteristics of a single crystal. Crystallographers are agreed that each boule is a single crystalline individual, with the axis roughly perpendicular to the plane of formation—that is to say, running from the point of attachment of the pedestal to the top of the mass. On the top of the boule one invariably finds a mass of symmetrically-arranged facets, which Dr. Herbert Smith has found to correspond with the fundamental rhombohedron of corundum. Judging by analogy with other materials, one would expect at first sight that a fused mass formed in this way would be either a heterogeneous mass of minute crystals, or entirely amorphous, possessing the structure characteristic of glass. It is well known, for example, that under similar conditions pure silica yields "quartz glass," which is extensively manufactured at the present time. One is tempted to dwell upon this point, and discuss its bearing on such matters as the devitrification of glass, but it would be entirely out of place to do so in the present paper.

Then, again, there is the matter of colouration. One would like very much to know what is the state of combination of the chromium in a ruby, and whether the colour is produced by chromium aluminate in solution or metallic chromium in molecular suspension. In glass, as is now well established, this colour is produced by the optical effect of ultra-microscopic spheres of metallic gold or copper, but there seems to be no parallel between the two cases.

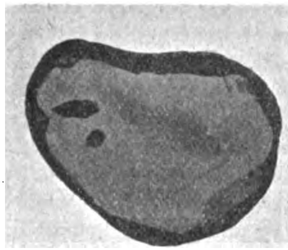
A point of more practical interest is the fact that although the artificial corundum is a true crystal it possesses the shape and formation of a congealed liquid or glass. The practical interest of this lies in the fact that it affords the only means of distinction between this artificial corundum and the naturally-formed gem-stone. Being of exactly the same composition and crystalline structure as the natural mineral, it cannot be identified by any of the physical tests I briefly referred to above. For all practical purposes the artificial ruby *is a ruby*, and one can only deny that it is a "genuine ruby" if this word is held to connote essentially a product found in the earth and not made by man.

And yet, owing to the curious anomaly of its structure, the artificial product can almost invariably be distinguished from the natural with the greatest ease. In the naturally-formed stone any foreign matter which may be present is coerced into following the lines of growth of the crystal, and more particularly bubbles of gas which may be present in the liquid are

distorted from their natural shape so as to accord with this symmetrical growth. It is the great exception to find a natural ruby entirely free from such inclusions, which generally form irregular cavities with a decided tendency to geometrical shape.

It is very common also to find the structure

FIG. 6.

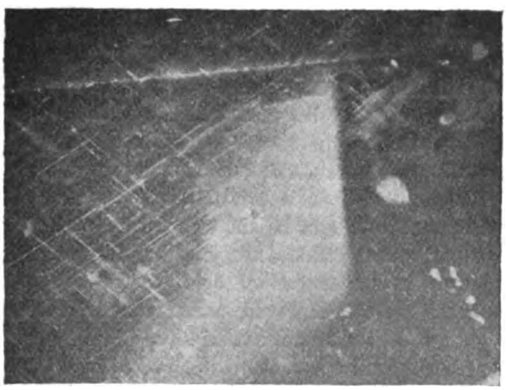


SECTION OF NATURAL RUBY, × 10.

technically known as "silk" caused by microscopic bubbles drawn out into a series of parallel canals, all lying in one plane. Any variation of colour in different portions of the stone also follows the lines of growth in this manner (Figs. 6 and 7).

In the artificially-produced corundum, on the other hand, although the particles arrange themselves symmetrically, any air bubbles that are entangled in the successive globules remain undisturbed, and appear as naturally spherical bubbles in the finished product; and, moreover, if one globule differs slightly from another in the proportion of chromium, the resulting

FIG. 7.

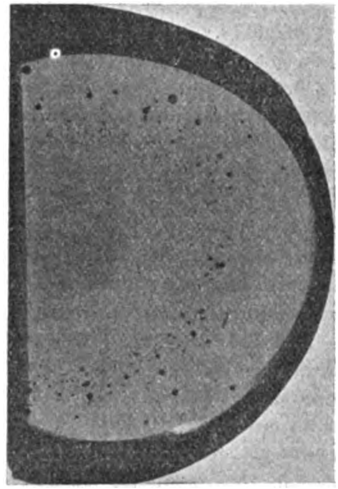


SECTION OF NATURAL RUBY, × 100.

difference in colour follows the form of the mass as a whole, the zones of colour being circular (Fig. 8).

As some of the air entangled between the fine particles fed into the blowpipe almost invariably fails to make its escape during the brief fusion, the presence and form of the bubbles is in this way sufficient to identify the artificial process of formation.

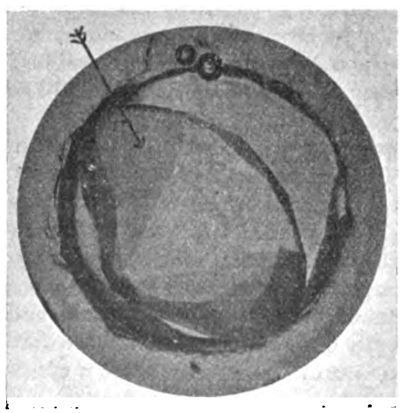
FIG. 8.



SECTION OF ARTIFICIAL RUBY, × 10.

In the great majority of cases examination of the cut stone with a lens is sufficient to decide the point, but in doubtful cases a more minute examination may be made by placing the stone in a little cell filled with highly-refracting liquid, in order to secure regular illumination, and examining it under the microscope by transmitted light, when the minutest trace of structure can be detected (Fig. 9). In

FIG. 9.



SMALL ARTIFICIAL SAPPHIRE, MOUNTED IN CELL, × 10, SHEWING MINUTE BUBBLES.

the case of an absolutely flawless stone it would be impossible to decide whether it were natural or artificial, but such stones are so rare that this case is almost theoretical.

It is claimed in some quarters, it is true, that "experts" can invariably distinguish the artificial product merely by reference to the colour, which is said never to be exactly the same as that of the natural stone, much as this latter varies. Personally, however, I am rather sceptical on this point, as one knows that experts claim in a similar manner to distinguish between one species of natural gem-stone and another by colour alone, and their results are not *always* in accordance with scientific tests. At any rate such dexterity can only be acquired by a lifetime of specialised experience.

As I have already indicated, spinels may be produced artificially by the same process as corundum, adding the necessary magnesia to the alumina, and the same remarks apply to the production and identification of this species as to corundum, the artificial stone being identical with the natural in all respects except those to which I have just referred.

As regards the remaining transparent gemstones, which fall into a group by reason of the fact that they contain silica as an essential component, their artificial production is of little importance. They cannot be produced by the same process as corundum, owing to the fact, already alluded to, that under such conditions both pure silica and compound silicates yield an amorphous product, which has not the optical properties of the natural stone. One is constrained, for the artificial production of the crystalline material, to fall back upon methods similar to those employed in the earlier attempts to obtain ruby—obtaining the requisite composition by chemical reaction and maintaining the mass at a temperature just above its fusion point for a sufficient time to allow the silicate to crystallise out.

Topaz, garnets, and zircon have been produced in this way experimentally as a matter of scientific interest, but the small stones produced have no commercial value, and to describe their production in detail would only weary you to no purpose. The majority of these stones are of such common occurrence in nature, and consequently of such little value, that their artificial production in this manner is not a commercial proposition.

An exception, however, must be made in the case of emerald, which ranks next in value to corundum, and many attempts have been made to produce it artificially. Reconstructed emeralds have been made by the Verneuil process, but these are, of course, amorphous, and do not possess the double refraction and other properties consequent upon the crystalline structure of the natural stone. The problem of producing this stone artificially has not as yet been solved in fact. I am quite aware in saying this that recent newspaper reports lead one to believe otherwise, but, as in the case of the diamond, such reports indicate either remarkable foresight on the part of the writers or show that their imagination is developed at the expense of their powers of accurate observation.

There remain now to be considered those precious stones which are opaque, and owe their beauty entirely to colour and structure.

Turquoise is a stone formed under conditions which are easy to reproduce, and its artificial production was successfully accomplished, many years ago, by precipitating hydrated phosphate of aluminium with the requisite proportion of copper phosphate to give it the colour, and subjecting the precipitate whilst still damp to hydraulic pressure for a considerable time. Prepared in this way the artificial turquoise is so nearly identical with the natural that its identification as a matter of considerable difficulty. There is, however, generally a slight difference in the specific gravity, hardness, and index of refraction (when this can be measured), which will serve to distinguish it on careful examination. The only point in which there is any decided difference between the two is the behaviour on heating, but as this involves the destruction of the stone it cannot be offered as a practical test.

Opal consists essentially of what is known as colloid silica, that is, silica in the amorphous state and combined with water. The play of colour one associates with it is entirely an optical effect, due to an accidental structure of the stone, which is permeated by a number of minute fissures, between which a thin film of air penetrates, the extreme thinness of this film causing the optical effect known as interference. If a piece of opal is powdered it is no longer coloured, as would be the case with a ruby or sapphire, but yields a dirty white powder, and generally a specimen of opal, as found, only shows the structure in parts, the remainder being dull and lustreless like flint.

This peculiar structure is, moreover, by no means confined to opal, but may occur in any mineral deposited under similar conditions. In the mineral known as Lumachello, or fire-marble, for example, the same effect is seen in a limestone. But opal is the only mineral which combines this structure with sufficient durability for use as a gem-stone, and in this connection

it should be remembered that, as a matter of fact, it only just possesses sufficient hardness for this purpose, and is one of the softest and least durable of all the precious stones. This fact, combined with the fragility consequent upon its structure, has involved the opal in a mass of superstition and romance from time immemorial.

Although it has this unfortunate drawback, opal is, at any rate in my estimation, the most beautiful of the precious stones, and when one appreciates the reason of its beauty it will be readily understood that its artificial production, or even successful imitation, presents almost insuperable difficulties.

It is true that a somewhat similar play of colour can be imparted to glass by rendering it translucent by a slight addition of arsenic or tin in the making, and by etching the surface in various ways, and such iridescent glasses are often found naturally as the result of decomposition, but this is merely a surface effect, and such specimens cannot be cut to advantage; moreover, they lack the beauty caused by the fire permeating the entire substance of the gem. The opal ranks with the diamond, therefore, in resisting attempts at artificial production, and is even superior to it in that it cannot be really successfully imitated.

I come finally to the pearl. This, of course, differs from all other precious stones in being entirely of organic origin. The peculiar lustre of the pearl, like the colour of the opal, is due rather to its structure than its composition. It is formed in the oyster by the deposition of successive layers of calcium carbonate round some central object, and consists of an innumerable number of thin overlapping laminæ of the crystalline variety of this substance known as aragonite. These layers being semi-transparent, the light falling on the surface is partially reflected from the surface and partially transmitted into the stone, where it suffers reflection from the surface of lower layers (Fig. 10).

To produce this complicated structure artificially is practically impossible, unless one can describe as an artificial pearl that formed by the oyster in response to the deliberate introduction of irritant foreign matter by human agency. But in this case, who shall decide where nature ends and human ingenuity begins? Perhaps the well-known Japanese pearl may be correctly described as artificial pearl, although the oyster has a great deal to do with it.

Such pearls are formed by introducing a mother-of-pearl shape between the shell and mantle of the oyster and then leaving the oyster alone for a time to allow it to convert this into a pearl by the deposition of several layers of nacre. The mass is then removed from the shell and converted into the semblance of a true pearl by supplying a back of mother-of-pearl. Such pearls, however, never have the fine orient of those produced under normal conditions, and they can readily be detected by examining the back, when the lustreless mother-of-pearl and the line of junction can be detected.

Of course, wonderful imitations of pearl are made in various ways, which are difficult to distinguish from the natural article by casual examination. One method of preparation is as follows:—Small hollow spheres are blown in opalescent glass, coated inside with a preparation of fish scales, and then filled up solid with wax. Such imitations are identified by examination of the hole or by putting a spot of ink on

FIG. 10.

SECTION OF PEARL, × 50.

the surface, when the reflection from the inner surface of the glass is seen. These empirical tests are usually sufficient, and it is rarely necessary to resort to testing the specific gravity and hardness, which provide further means of identification. It is worthy of note, however, that such imitation pearls are unique amongst imitation gems in that, in some respects, they are actually superior to the natural article. They are considerably harder for instance, and their lustre is not affected by constant wear.

In conclusion, I would like to refer very briefly to the present position of gems from the economic point of view. It is, perhaps, natural that the considerable influx of artificial gems in recent years, more particularly of the corundum species, has led to a great deal of controversy and difference of opinion as regards their merits. On the one hand the vendors of the artificial stones often publish extravagant

statements as to their defying identification, which, as I have shown you, is all nonsense. On the other hand, those interested in maintaining the prestige of the natural article make equally unreasonable statements, to the effect that such artificial productions, to quote a recently published circular, "are as worthless as the jewellery from a Christmas cracker." I have, I hope, clearly shown you the immense difference that exists between the imitation and the artificial ruby, taking an example; the former, it is true, depreciates rapidly in use, and deserves such a description, but the latter has absolutely all the essential qualities of the natural stone, and to place the two on the same plane as worthless trash is unfair to modern science and ingenuity. It must be clearly understood that there is no essential difference discernible between natural and artificial ruby as regards their beauty and their durability, which, as we have seen, are the two great items in the intrinsic value of a stone. But, of course, the price of a stone is chiefly determined by that third factor, which I have not so far taken into account—namely, rarity. Personally, I must confess that I have never been able to see why one should value a thing for no other reason than that it is difficult to get, although I suppose here I am in a hopeless minority, and that it is and always will be human nature to take this view.

It would serve no useful purpose to enter into that fruitful subject of controversy, the price of an article due to extrinsic causes, but I may say this—that whilst to me personally one is as good as the other, if any man is prepared to pay £100 for a natural stone when he can obtain essentially the same thing, artificially produced, for five, he is absolutely entitled to get it; and I would not wish you to think that I would defend for a moment the man who attempted to supply artificial as natural. But if this is so, it is still more the case that nobody has any right to supply anyone with paste under the name of artificial (or synthetic, or scientific, if these names are preferred) gem. I do think that the distinction between the two should be clearly recognised, and that it should not be permitted to use the term artificial indiscriminately. At present this is being widely practised; every day one sees offered for sale "rubies, emeralds, sapphires, and pearls artificially produced and having all the properties of the natural stone." Now, as I have indicated, such a thing as an artificial emerald answering this description is unknown, and, as a matter of fact, the stones supplied under this title are, as a rule, nothing more nor less than paste imitations, the public being deliberately led to believe otherwise. There is in this case, as I have indicated, a real practical difference between the two articles, not merely a question of opinion.

Again, one must deprecate the custom that has sprung up of arguing that, because "a rose by any other name will smell as sweet," a "scientific" stone will be as good by any other name than its right one. When synthetic yellow sapphire is called "scientific topaz," perhaps no serious fraud is perpetrated, although it is misleading, but when artificial white sapphire is openly and deliberately sold at a fancy price as "synthetic diamond," with the support of the press, I for one consider that matters are going too far, and that this is being done at the present moment anyone can verify for himself. All these misrepresentations may bring wealth to individuals, but they tend to bring into disrepute the artificially-produced gem, and instead of allowing it a place of its own as a distinct achievement, cause it to be looked upon as a spurious make-believe.

However, I did not come here for the purpose of discussing this aspect, and I will not dwell upon it further. I have, as far as possible, given you a *résumé* of the whole subject, and I will detain you no longer, except, if I may add one more word, to acknowledge the fact that my ability to bring this paper before you is very largely due to the assistance I have received in many quarters, and more particularly from Mr. E. Hopkins, whose enthusiasm on the subject of the technology of precious stones is only exceeded by his knowledge and experience. I am indebted to him, not only for much advice and information, but also for the loan of the specimens from which I have prepared the illustrations to this paper.

DISCUSSION.

The CHAIRMAN, in opening the discussion, expressed his great pleasure at having heard such an admirably clear paper, many of the points in which were new to him. It was the first simple account he had heard of the production of synthetic stones, and his first opportunity of witnessing such interesting and clearly intelligible pictures. Those towards the end of the lecture showed well the differences between the reconstructed and the natural stones, and those slides appealed more eloquently to an audience than any amount of written description. They were practically seen by the audience under the microscope. Mr. Heaton had reminded him (the speaker) of the occasion when he lectured before the Society

fifteen years ago, and it was a satisfaction to him that he had, at that date, been able to call attention to all the methods which had been mentioned that evening, even including X-rays, which had then just become available. He also said at the same date that he thought the time could not be far distant when sapphires could be produced as easily and perfectly as rubies were then beginning to be made. The difficulty seemed to be the reproduction of the peculiar blue colour. He also mentioned in his own lectures the refractometer, the simplest and most effective way of testing a stone by its refractive power. At the time it was a scientific instrument available only to the expert scientist; but Dr. Herbert Smith, with the aid of Mr. Steward, had now constructed an apparatus which was within the reach of any worker, and enabled him to determine, without special knowledge, the refractive index of a stone to a great degree of accuracy. If that were combined with the use of a heavy liquid for determining the specific gravity, it constituted an almost unerring means of determining whether the stone were natural or artificial. When, fifteen years ago, he spoke on the natural and artificial or reconstructed ruby being distinguishable by the air bubbles in the latter, he was only basing his remarks on a limited experience. He was glad to find that, despite all the efforts which had been made to approximate the artificial to the natural stone, that still remained an unfailing distinction. The question was a very interesting one, because of the light it might throw on the manner of production of the precious stones in the earth's crust. For instance, the description of the production of the diamond naturally bore a close resemblance to the manner of creation of the diamond in the masses of meteoric iron which fell from the sky. The research which had been devoted to the production of stones artificially, had pointed out the possibility of adding to the repertoire, for a beautiful series could be produced of which there were no parallels in Nature. Robert Boyle, in 1665, seemed to have been the first person to make scientific experiments on the distinction between artificial and natural precious stones, and he pointed out how important it was to use methods which did not destroy the stones; and for this, among other reasons, recommended the specific gravity as the test. He (the speaker) did not know why paste should be condemned because it was paste, so long as its true nature were known to the purchaser. He had long admired the charm of the Roman gems in the British Museum, and was interested to hear that they probably originated in Nubia. He had never seen anything which illustrated so clearly the reconstruction of rubies as Mr. Heaton's demonstration. He had imagined that the pedestal on which the material was fused was kept in rotation; he did not know whether that was no longer so. The lecture was not one of those which ended merely in talk; it was a scientific and expert exposition, and he hoped to hear criticisms and enquiries from those present, who might include many with practical experience of precious stones.

Mr. J. H. Steward declared that he had no expert knowledge of precious stones, but he had found the paper extremely interesting. His experience had been more in connection with instruments. Fifteen years ago he was present at the lectures given there by the Chairman, and he was much struck by the description of the refractometer, and he thought it would be a very useful instrument if it were further developed. Without knowing very much about it, he took it in hand, but was not quite so successful as he had hoped to be. But Dr. Herbert Smith, of the British Museum, happened to know that he was experimenting with it, and offered his assistance. With that assistance an instrument was evolved of great practical utility, not only for gem determinations, but in other industrial matters. Much gratitude was due to Dr. Herbert Smith for the care which he had bestowed on the improvement of the instrument.

Mr. E. Hopkins thought rarity had a great influence on the value assigned to stones, as in other matters, such as old books, china, furniture, etc. Other articles were quite as useful and valuable intrinsically, but rarity greatly enhanced the market price. Within the last three months two rubies had been sold in London for £1,200, notwithstanding the energy bestowed on the manufactured article. Although the pearl was a softer material than its artificial substitute, the price of that also had risen 50 per cent., and was still rising. Recently a law had become operative in Paris that all manufactured gems must bear the prefix "imitation"; the term "synthetic" was not deemed sufficient. That was, perhaps, carrying the matter rather far, but the energy at the back of the artificial article seemed to have made such a law necessary. White sapphires had been sold as diamonds, and, instead of 4*s.* or 5*s.* per carat, they had realised £5 per carat. One of the best safeguards was to require a detailed invoice with such purchases, as a precaution, especially as the prices differed so greatly, and so much fraud was being perpetrated in such matters.

Mr. B. J. Tully remarked that the slide of the ruby selected for showing on the screen had the structure technically known as "silk"; but such marking was not always present, and it was scarcely a typical test of the true ruby, though where a white sheen was seen on a specimen, it was a certain identification. The microscope was the only real test left, but it was unsatisfactory, as it could be used only for very thin and small specimens. The difficulty of making the sapphire originally was concerned with the colour; cobalt was used, and only by analysis of the real stone was cromium discovered as a constituent. The pretty slide of a pearl which was shown was that of a Scotch specimen; and it was the prismatic structure

in the centre which gave rise to the dull lustreless sheen. It was scarcely a typical specimen of Oriental pearl; the latter could not be ground down thin enough to form a microscopic section; it had a laminated structure, and would split into pieces in grinding. The beautiful slides shown were due to Mr. Heaton's ingenuity. Artificial stones seemed to have reached their zenith, and he hoped they would as quickly decline again. It was gratifying to know that natural stones were now increasing in price more than even they did when artificial stones were not in competition with them, and there was a greater demand for them. The action of one or two societies, and the exposures of fraudulent sales, would do much to reduce the number of artificial stones being worn.

Mr. Frank Stevens pleaded for greater accuracy of definition in the matter of precious stones and gems. Nowadays it was the custom to include among precious stones such things as pearls, which were an animal product, not mineral. He thought a gem should be held to be an engraved mineral, as distinguished from a precious stone which had been cut and facetted by the lapidary. He asked as to the possibility of procuring a synthetic jargoon by fusion of zirconium silicate in the blowpipe, so as to bring about the range of colour from deep orange-brown to apple-green.

Mr. W. S. Lockhart said that as he understood artificial gems always had air included in them, that would surely make a difference in their specific gravity. He had usually found that the smallest error due to this was apparent.

Mr. Heaton, in reply, said the Chairman's remarks were of great interest to him. He had not properly appreciated the work of Boyle on the specific gravity as a means of identifying precious stones. There was a legitimate place for paste for those who did not want to pay for real stones, so long as they understood what it was they were buying or wearing. The pastes mentioned by the Chairman came from Rome, but they were later than the Nubian ones. He shortened his historical account in order to spend more time on the practical side; the early history provided enough material for a lecture by itself. It was true that the revolving pedestal was used in the old apparatus for reconstructing rubies, but it was not necessary in Verneuil's ingenious process. Scientific tests gave much more than a mere opinion; they were always right, and often contradicted an expert opinion. That was most important in view of the skill of some of the imitators. With regard to the silky look, he took extreme examples in each case. It was very exceptional to find a natural ruby which had not some traces of the parallel structure or of inclusions. He did not agree with Mr. Tully that the microscope was not of much use; one could focus it to the centre of the stone, and by immersing the latter in a highly-refracting liquid one could examine the minutest detail of structure, and his own experience was that microscopic examination was of the greatest value. The pearl shown was not an Oriental one, because it was impossible to prepare a decent microscopical section of a proper Oriental pearl. With regard to the synthetical jargoon, the difficulty with all the silicate group was that one could not produce it artificially by the Verneuil process, because it would not then be crystalline but amorphous. Synthetic jargoon had been produced on a small scale by the process of crystallising out with a solvent, but it was not a commercial proposition to make the stones in that way. Zircon was not a very valuable precious stone; if it were rare it would be a serious competitor to the diamond; it had a high refractive index, and its optical properties were very good. With regard to alterations of specific gravity caused by inclusion of air, those could of course be detected if sufficient refinement of method could be achieved. But in the great majority of cases the alteration thus introduced would not be greater than those occurring in the natural stone through slight variations of composition.

On the motion of the Chairman, a vote of thanks was accorded to Mr. Heaton for his paper, and the meeting terminated.

THE LÖTSCHBERG TUNNEL.

The successful piercing of the lofty mountain range which lies to the south-west of the Jungfrau, and separates the Bernese Oberland from the Canton of Valais, is certainly a triumph of Swiss engineering skill and enterprise. It has broken the record in rock boring. The Lötschberg tunnel on the Berne, Lötschberg and Simplon Railway, now in construction, is designed to connect the network of northern Switzerland with the Italian lines. It will, when completed, form one of the principal approaches to the Simplon tunnel, and shorten the distance between Calais and Milan, *viâ* Bâle and Berne, by about fifty-three miles, reducing the time required for the journey by at least three hours.

On the north side, the new line starts from the station of Frutigen (Berne), and, following the course of the Kander River, will enter the tunnel at Kandersteg. From the southern end at Goppenstein, the line winds along the steep mountain-side of the Lötsch-Thal, passing through no fewer than twenty-one tunnels and over ten important viaducts, reaching the Rhône valley near Gompel, and, following the course of the river, will join the Simplon railway near Brigue. The works of this line are being carried out by the "Entreprise générale du chemin de fer des Alpes Bernoises."

The Lötschberg tunnel was commenced on October 16th, 1906, and is 14,535 metres 41 centi-

metres in length (9 English miles). The junction of the two headings was made on March 31st last, and so accurately had the work been planned and carried out by the engineers in charge, that the deviation in the line of the tunnel was found to be only 257 millimetres (10·12 inches); the difference in the levels 102 millimetres (4 inches); whilst the length was found to be 41 centimetres (16·14 inches) shorter. The piercing of the mountain has occupied exactly 53½ months. Its construction has been attended with many difficulties.

Of the four great Alpine tunnels, the Lötschberg will, when completed, be the third as regards length, the longest being that of the Simplon, which is 9¼ miles, and occupied about eight years in construction; it was opened in 1905.

The St. Gothard tunnel, opened in 1880, the second in length, is 14,920 metres (9¼ miles) in length, and occupied 111 months in construction; whilst the first of the great Alpine tunnels, opened about forty years ago, is 12,133 metres (7½ miles) long.

The average length of heading driven from both sides daily was 12·46 metres (40·35 feet). The daily average on the north side, for which the Meyer rock-boring machinery was used, was 7·84 metres (25·72 feet), whilst the progress made on the south side, where the boring was done by the Ingersoll drills, averaged 5·12 metres (16·8 feet). On the north side, the greatest distance tunnelled in a single day was 13·20 metres (43·3 feet) in the limestone, and 10·60 metres (34·77 feet) in the granite. The average length driven per month was 310 metres (1,017 feet) in limestone, and 261·80 metres (858·92 feet) in granite. The daily average for the same period was 10·69 metres (35·07 feet) in limestone, and 8·95 metres (29·36 feet) in granite.

EMPIRE NOTES.

British Trade with Canada.—A Blue Book has just been issued by the Board of Trade embodying a report by H.M. Trade Commissioner for the Dominion of Canada. The report presents a general survey of the prevailing conditions in Canadian markets, and also gives a number of tables and figures indicating the expansion of Canada's trade, and describes the business methods of the representatives of the different nationalities competing for a share in the industrial and commercial development of the Dominion. A section of the report provides an analysis of the import trade of Canada, making special reference to the relations of American and British producers to the Dominion market. The Commissioner points out that there is a keen and unremitting struggle going forward along the whole line of British and American competitors for the trade of that country. The United States, of course, possesses an advantage from its geographical position, and the close social intercourse existing between a large section of its people and those of Canada, and also from the cheapness of communication. On the other hand, Great Britain profits by the preferential customs granted thirteen years ago, and by the long-standing connection between the British producer and the Canadian consumer, and by the high reputation for excellence of quality and workmanship and businesslike dealings which have given her pre-eminence in the markets of the world. While it may be said that British trade with Canada, in manufactured goods, is holding its own with America, it is pointed out that there are some trades which are not doing so. The reason for this is not attributed to the lack of quality in British goods, but in the failure to adapt them specially to the Canadian market. The Commissioner points out that in respect to capital, the investment of American money in British Columbia is noticeably large, and at least half of the capital employed in the mines of that province comes from the United States. Against this there is to be placed the large influx of British capital, which is widespread throughout the Dominion. Many instances are also given in which British goods are more than holding their own, and the report shows that if up-to-date methods of fostering trade are adopted by British manufacturers they need not fear any competitors.

British Trade with Australia.—Mr. C. Hamilton Wickes, H.M. Trade Commissioner for Australia, when interviewed recently, gave some interesting particulars of British trade with Australia. He stated that the imports into Australia of goods from all countries in 1908 totalled £49,799,273; in 1909, £51,171,896; and in 1910, £59,456,238. The goods of British origin in 1908 amounted to £25,274,661 or 50·76; in 1909, £25,862,618 or 50·54; and in 1910, £29,877,209 or 50·25. "That shows," he said, "that the increase in 1910 was £4,014,591, which is enormous. The trade of our two chief competitors in 1909 is represented by a total of imports from the German Empire of £4,538,612, and from the United States of £5,935,740. The increase of goods of British origin in 1910 was therefore, in round figures, within half a million of the total German imports into Australia for the previous year. Apparently Great Britain shows a decrease of the total imports, but in this total of imports by the Commonwealth are included such items as timber, kerosene oil, rubber, raw tobacco, tea, coffee, cocoa beans, fresh fruit, fresh vegetables, fresh fish, and rice, articles which England does not and could not produce, and never will produce. When you come to examine what the trade of Great Britain is, and the percentage of British trade with Australia, deducting these items, you will find that the British share has increased over 63 per cent., and instead of showing a decrease over 1908-9 it shows an increase."

Oil Fuel for the Australian Navy.—The scheme of Australian defence recently promulgated by Admiral Sir Reginald Henderson, will involve the

Commonwealth Government in the expenditure of a large sum of money annually for maintenance, in addition to its initial cost. To meet the necessary outlay, which the Government are quite ready to do, the question of the relation of the scheme to the trade and industry of the country is one of importance. It is interesting, therefore, to note that a contract is being placed with the Commonwealth Oil Corporation for the supply of oil fuel for the navy. Discussing this matter in the House of Representatives, the Hon. G. F. Pearce, Minister of Defence, who has recently made a thorough inspection of the works of the Corporation, said:—"I am thoroughly satisfied, from the businesslike preparation they are making, and the extent of the works, that there can be no doubt that in a short while they will be able adequately to supply all our requirements in the way of oil fuel for defence purposes. No one could go through the trip I have just accomplished without being impressed with the value of the industry to Australia from a commercial point of view. I think very few people realise the value of the shale-oil industry, or what its possibilities are." It is estimated that the oil industry will find employment for many thousands of workers.

Trade, Commerce, and Mining in Rhodesia.—Satisfaction is being expressed everywhere throughout Rhodesia at the excellent position which is revealed by the official figures for Rhodesian trade for 1910. The imports by Southern Rhodesia of United South Africa products amounted to £467,907, against £438,660 in 1909, and of £2,318,414 other than South African products, as against £1,775,345 in the previous year. Of the latter, 64 per cent. was imported from the United Kingdom, 4·1 per cent. from other parts of the British Empire, and 31 per cent. from foreign countries. The value of the exports of Southern Rhodesia for 1909 was £2,801,811, and for 1910, £2,797,906; the value of goods re-exported for 1910 bringing the total to £3,199,956. North-western Rhodesia also shows an appreciable increase on 1909, and the mining industry of Rhodesia is in a similarly satisfactory condition. At the annual meting of the Chamber of Commerce, the President stated that if the requirements for labour were satisfied, there would in five years' time be 80,000 natives employed in Rhodesian mines against 30,000 at present. Two new companies were registered in Southern Rhodesia during 1910, the nominal capital of which is about one million and a quarter. The dividends of the various mining companies amounted in 1910 to £905,999, as against £481,000 in 1909. The value of the output from small gold claims registered in 1910 was £76,687, or over £46,000 more than in the previous year. Capital is being found for development work in the mines which, at depth, are proved to possess permanent and continuous ore bodies.

Indian Industries.—A novel industry appears to be on the eve of development in India, where oil of good quality is being produced in considerable quantities from boiled sardines on the west coast of Madras. It is asserted that it is suitable for the jute, leather, and steel (tempering) trades, and for many other operations. The oil is said to contain a large amount of fish tallow (stearine). According to the Director-General of Commercial Intelligence at Calcutta, one of the most important industries of the country, that of wood-pulp, is showing marked signs of progress. Eight paper-mills are in operation, whilst others are approaching completion. The value of the output for 1909 amounted to £516,666, which is the highest on record. The wheat export from the Bombay Presidency was on an exceptional scale during the season 1909-10, the shipments being the largest for many years past. On the other hand, there has been considerable depression in the cotton and spinning industry, owing largely to the high prices ruling for raw material, and in part to the competition of imported goods, which was an adverse factor of some moment.

HOME INDUSTRIES.

Unemployment Insurance.—The Chancellor of the Exchequer's scheme of social insurance will shortly be unfolded, and although some of its main provisions are known, its full presentment is awaited with very deep interest. It is to cover sickness and invalidity completely, and it is said that it will touch unemployment. German pioneer work will help the Chancellor in his attempt to solve the problems of maintenance during sickness and infirmity, and the German system of joint contributions from the employer, the employed, and the State, is to be followed. But formidable as are the difficulties to be faced in the endeavour to create a satisfactory system under these two heads of insurance, they are much less so than those which will confront the Chancellor if he attempts to legislate for insurance against unemployment. Irregularity of employment is the most pressing evil of the present industrial system, and is clamant for a remedy. The unemployed may be divided into (*a*) those who cannot work owing to age or ill-health; (*b*) those who are incompetent owing to habits; (*c*) those who are able and willing to work but are unemployed from lack of demand. Class I. will be covered by sickness and invalidity benefits and old-age pensions; class II. need punishment rather than help; it is class III. with which unemployment insurance must be mainly concerned. There are no statistics available on which to found a rigidly accurate actuarial scheme, and even if they were available they would not necessarily form a trustworthy basis for the future. Taxation, emigration, increase of population, improvement in machinery and methods of working, relations with the colonies and other countries, all these and many other considerations must have their bearing upon the result of any possible legislation. It is safe to say that no system of unemployment insurance can either

be a preventive or a cure of the evil, but a well-devised scheme that will help the needy and worthy workman in the days of unemployment is not perhaps too much to hope for. But it is difficult to see how this gigantic subject can be satisfactorily dealt with by Parliament whilst it is in the throes of a great constitutional struggle. And better no legislation on such a subject than any which has not been thoroughly thought out and fully discussed.

The New Mines Bill.—The Coal Mines Bill has now entered upon the Committee stage, after being the subject of separate and joint conferences of the coalowners and miners. There will be keen fighting in Committee over several of the clauses. One of the stiffest fights is likely to be on Clause 60, which imposes restrictions on the use of electricity in mines. The opponents of the use of electricity in the coal-mining industry are to be found on both sides, some colliery owners and managers being as keenly opposed as are some of the men. In certain mines there is practically a complete absence of inflammable gas in the airways and working places, and here electricity has been accepted by managers and workmen, but the West Stanley disaster in Durham, and the explosion at the Hulton Colliery in Lancashire, have deepened the distrust of the workmen as to the safe use of electricity in mines. Clause 60 authorises the inspector of the district to enforce the withdrawal of an existing supply of electricity from any mine, subject only to an appeal to arbitration, but this does not satisfy the opponents of electricity, who want to see it withdrawn from all mines. Another clause, of much less real importance, is likely to be the subject of hot debate, namely, that which makes compulsory the provision of bathing accommodation at all collieries. The colliery baths in Germany have proved a distinct gain to the miner, but the colliery owners contend that the obligatory use of the bath by every workman before he leaves the colliery will be an endless source of irritation between the management and the men. The younger men may be willing to adapt themselves to the new conditions, but it is pretty safe to say that they will be resented and resisted by many of the older miners.

Electricity and Colliery Accidents.—In connection with electricity in mines a paper written by Mr. Robert Nelson, H.M. Inspector of Mines, appears very opportunely. Mr. Nelson reviews the accidents and deaths due to electrical causes recorded during the six years ending December 31st, 1910. These he divides into three divisions, (1) ignitions of firedamp, (2) underground fires, and (3) electric shock. There were five fatal ignitions of firedamp, giving rise to thirteen deaths; and in each case it appeared that the presence of gas was unsuspected. Two fatal underground fires and two deaths were recorded. In each case the insulation of the cable and the presence of woodwork aggravated the fire. One fire arose from the sparking of a continuous-current motor, and the other probably originated in the oil-switch of a three-phase motor. Electric shock was responsible for fifty-three accidents and fifty-five deaths, thus greatly outnumbering other electrically-caused accidents. Of the accidents, twenty-two were due to defective or non-existent earthing of electrical cables and apparatus, twenty were due to defective insulation of cables, nine to contact with uninsulated parts, and two to other causes. Of the twenty-four accidents on cables, twenty occurred on unarmoured cables, thus showing the urgent necessity for enclosing all cables and, as far as possible, all other underground electric plant in efficiently earthed armouring. As regards the influence of current, thirty-three out of the fifty-three accidents occurred on three-phase systems and twenty on continuous current. It would seem that proper protective methods may be relied upon to eliminate most of the dangers arising out of electricity in mines.

The Break-up of Estates.—Whatever may be the explanation—and authorities differ as to it—there is a tendency just now on the part of great owners to sell portions of their estates. Not long ago it was announced that Mr. Walter Long, whose family has been established in Wiltshire for several centuries, had decided to sell something like half his Wiltshire estates. Since then many other considerable landowners, notably Lord Onslow, have followed suit, and now it is announced that the Duke of Bedford is about to sell nearly the whole of his estates in Devonshire. It may be hoped that the tenants, or most of them, will be able to buy, since two-thirds of the purchase-money can remain on mortgage if desired. In Norfolk, an estate of 5,240 acres, of which more than 3,000 consist of agricultural land, is in the market; in Suffolk an estate of 6,000 acres is to be divided up and sold in lots; and in Shropshire a property of 3,500 acres will shortly be the subject of an auction. Lord Ilchester is getting rid of his estates in Hampshire and Wiltshire, and other landowners are mentioned as having the intention to sell very shortly. If these estates pass into the hands of competent and solvent occupiers the change may be welcomed. A single change of ownership would, more likely than not, be a disadvantage to the tenantry. The big landowners, whose families have been associated with the land for centuries, are usually generous landlords, the "new men," more frequently than not, are the contrary.

Bogus Banks.—A very much wanted Bill has been introduced in the House of Commons, having for its object the restriction of the use of the term "bank" to *bonâ fide* banks, undertakings of sufficient importance and stability to entitle them to use it. During recent years all kinds of commercial undertakings for lending and borrowing money have called themselves "banks." There

have been "loan and discount banks," "land and investment banks," "building banks," "financial banks," and other variations. Some of these have been stable concerns, honourably conducted, but most of them have assumed the title of "bank" merely to obtain credit on insufficient capital. The public, more especially the working classes, usually ignorant in such matters, have been the chief sufferers. The difficulty is to define a "bank," and to distinguish between a *boná fide* bank and one not entitled to use the word. Major White's Bill provides that every person, not being a limited company, who commences to carry on the business of banking after the Act, shall deposit with the Board of Trade £20,000, to be invested in trust securities, and to be available for satisfying creditors. An annual balance-sheet, and profit and loss account, must be prepared, and every five years an independent investigation must be made for the Board of Trade into the financial condition of the concern. Whether the Bill would be adequate to accomplish its object, whether it might not encourage the public to assume the solvency of the concern to be guaranteed by the Government, when in fact it was not, are points upon which opinion will be divided, but whatever the merits of this particular Bill, its object cannot be too highly commended; and it ought not to be above the capacity of our legislators to stamp out the bogus "banks," which, by means of an honoured name to which they have no right, prey upon a credulous public.

Australian Shipping Laws.—It may be assumed that the Federal Ministers now on their way from Australia will be empowered and instructed to discuss with the Imperial Government the provisions of the Australian Navigation Bill. The protest made by the Liverpool Shipowners' Association has been seriously considered by the Federal Government, but it is not at present prepared to make all the concessions asked for. The principal clause objected to is 206, which enacts that "a steamship in respect of which a certificate of survey, granted or recognised by the Board of Trade of the United Kingdom, has been issued, shall, while that remains in force, be exempt from survey under this Act." The Board of Trade would like to see the exemption extended so as to cover all vessels holding Lloyd's or the International Registry's classification survey status, but the Australian Government are reluctant to concede this point.

OBITUARY.

James George Henry Glass, C.I.E. — Mr. J. G. H. Glass died at Naples on the 21st inst. Born at Bracadaile, Isle of Skye, in 1843, he entered the Indian Public Works Department in 1862, and was posted to the Central Provinces. In 1885 he was appointed Provincial Secretary of the Department, a post which he held for nine years in combination with the chief engineership. He was created a C.I.E. in 1890; four years later he was transferred to the United Provinces as chief engineer and secretary of the buildings and roads branch; and in 1896 he was again transferred to Bengal, where he acted in a similar capacity. He was a member of the Lieutenant-Governor's Council. He retired from the service in 1898, and on his return to this country he served on the board of visitors of Cooper's Hill Indian Engineering College until it ceased to exist.

Mr. Glass became a member of the Royal Society of Arts in 1900. He wrote a paper on "The Great Landslip at Gohna, in Garhwal, and the Measures adopted to Prevent serious Loss of Life," which was read before the Indian Section in 1896, during the author's absence in Bengal, where he was then Chief Engineer and Secretary of the Public Works Department. He received the Society's silver medal for the paper.

GENERAL NOTES.

The Turin International Exhibition, 1911.—Great activity is being displayed at the present time in every department of the exhibition at Turin in order to have all in readiness for the opening, which will take place on the 29th inst. The "International Exhibition of Industries and Work," as it is entitled, besides occupying the whole of the gardens of the Valentino Castle, on the left bank of the Po, extends for a distance of three kilometres (nearly two English miles) on both sides of the river, covering an area four times greater than that of the last exhibition, held in the same gardens in 1898. Here are situated the principal exhibition buildings, which comprise the gallery of machinery in motion, and that of electricity, together occupying an area of 60,000 square metres (14¾ acres). The galleries allotted to chemical and extractive industries, manufactures, silk, public works, railways, etc., cover about 70,000 square metres (17 acres). The British section occupies a prominent position in these gardens, covering an area of about 20,000 square metres (nearly five acres). The Hungarian section, which is also on the same side of the river, is considerably less in extent, occupying about two acres. Among the other many attractions on this side of the river may be mentioned the "Palace of Fashion," the palace of journalism, the exhibition of musical instruments, and the great Hall of Festivals. The buildings erected by the other nations are mostly on the right bank of the river, the space allotted to some of the principal countries being: France, 14,000 square metres (3 acres); Germany, 30,000 square metres (nearly 7½ acres); Belgium, 6,000 square metres (1½ acres); Russia and the United States, 8,000 square metres (about 2 acres) each, whilst the exhibits of the other nations are proportionately less extensive.

Altogether the total area covered by buildings is estimated at upwards of 400,000 square metres (about 100 acres). In addition to the two existing stone bridges over the Po, viz., the "Ponte Umberto I." and the "Ponte Isabella," communication between the two sides of the river is established by the fine monumental bridge, provided with a moving platform, above which is a second roadway. Two aerial transporters worked by electricity also cross the river, where an efficient service of motor-launches for conveying passengers is provided.

Export of Raw Silk from Japan.—The quantity of raw silk exported from Japan to Europe has increased steadily during the last five years. The following figures give the number of bales shipped from that country during the six months ending December 31st, 1910, as compared with those of similar periods of the previous years:—

	No. of bales exported to Europe.	America.	Total.
1906	20,162	48,650	68,812
1907	22,893	40,041	62,934
1908	18,698	53,314	72,012
1909	27,990	51,508	79,498
1910	26,421	63,003	89,424

Opossum Farming in Australia.—On account of the recent rising market for opossum skins in Australia, chiefly because of their large export, especially to the United States, much attention is now being given to the possibility of breeding opossums for their fur in timbered parts of Australian farms. Several experiments of this kind have already been tried profitably. It is apparent that the future demands for Australian opossum skins can only be met by carefully breeding these animals commercially. An interesting suggestion in connection with the possibilities of opossum farming has been made by the Director of the Zoological Gardens at Sydney. He believes that every eucalyptus tree on Australian farms can be made productive by providing food for opossums, and that for every good-sized gum or eucalyptus tree the income of the farm might be increased by about two shillings. He is of opinion that a proportion of one male to three or four females would be an economical number to have, and that a simple method of keeping stock would be to place a number of small boxes, large enough to hold one opossum, in the trees and in an accessible position. The opossums would use these to sleep in during the daytime, when it is their habit to sleep, and the boxes would make it convenient to catch and examine them. The cultivation of maize and of chief fodder crops is also recommended in order to increase the opossum-carrying capacity of the farm and to enable the opossums to reach maturity more quickly. The chief food of the animals, however, is eucalyptus leaves, which in Australia, the native home of the eucalyptus tree, are naturally very abundant.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

May 3.—A. W. Gattie, "Improvements in the Transport and Distribution of Goods in London." James Swinburne, M.Inst.C.E., F.R.S., will preside.

May 10.—Hal Williams, M.I.Mech.E., M.I.E.E., "Beet Sugar Factories."

May 17.—Professor Raoul Pictet, "Les Basses Températures."

May 24.—Frank M. Andrews, "Architecture in America." Sir Aston Webb, C.B., R.A., F.R.I.B.A., will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

May 25.—W. R. H. Merk, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India."

Colonial Section.

Tuesday afternoon, at 4.30 o'clock:—

May 9.—F. Williams Taylor, "Canada and Canadian Banking." His Grace the Duke of Argyll, K.T., G.C.M.G., G.C.V.O., will preside.

Cantor Lectures.

Monday Evenings, at 8 o'clock:—

Alfred E. H. Tutton, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

Syllabus.

Lecture I.—May 1.—*The External Form of Rock Crystal and Chemical Character of its Substance.* Early Observations of its Geometrical Shape, and Conclusions drawn therefrom as to the Nature of Crystals in General—The Modern Conception of a Crystal—Measurement of the Angles between the Faces of a Quartz Crystal, and the Facts thereby Deduced—The Plan or Scheme of Arrangement of the Faces, and the Occurrence of Right and Left-handed Varieties of Quartz.

Lecture II.—May 8.—*The Internal Structure of Rock Crystal, and the Means we possess of Elucidating it.* The Chemical Molecules of Silica, and their Arrangement in a Space-lattice — The Influence of the Arrangement of the Elementary Atoms in the Molecule of Silica in Determining a Right or Left-handed Screw Structure—The probable Disposition of the Atoms and Molecules in the Right and Left Varieties of Quartz, and the Effect of this Internal Structure in determining the Outward Geometric Form—Revelation of the Oppositely Helical Structure by Etching and Liquid Cavities.

Lecture III.—May 15.—*Optical Evidence of the Two Complementarily Opposite (Mirror-image) Screw Structures.* Rotation of the Plane of Vibration of Polarized Light in Contrary Directions by the Two Varieties of Quartz—Experiments on the Artificial Reproduction of the Quartz Phenomena, in proof of the suggested Screw Structure—The Twinning of Quartz and Apparent

Enhancement of the Symmetry and Destruction or Modification of the Optical Activity thereby—The Interesting Case of Amethyst—The Magnificent Polarization Phenomena of Twinned Quartz.

LECTURE IV.—MAY 22.—*Scientific and Industrial Uses of Rock Crystal.* Its Thermal and Electric Properties, and its Transparency to Ultra-violet Rays—The Construction of Prisms and Lenses (including spectacles) of Rock Crystal, and their Advantages over Glass—The Use of Quartz for Balance Weights and in connection with the Interferometer—The Artistic Use of Quartz for the Carving of Vases and other Objects—Destruction of the Crystalline Structure by Fusion, and the Uses of Fused Silica in Fibres and Scientific Apparatus.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. A. E. H. Tutton, "Rock Crystal—its Structure and Uses." (Lecture I.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. H. Trustram Eve, "Agricultural Land and Local Taxation."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Mr. H. C. H. Shenton, "The Protection of Water-Supplies."

Chemical Industry (London Section), Burlington House, W., 8 p.m. Mr. C. Edward Sage, "The Testing of Creosote."

British Architects, 9, Conduit-street, W., 8 p.m. Annual General Meeting.

Actuaries, Staples Inn Hall, Holborn. W.C., 5 p.m. Mr. T. Bradshaw, "Notes on the Insurance Act, 1910, Dominion of Canada."

Concrete Institute, International Building Trades Exhibition, Olympia, West Kensington, W., 5.45 p.m. Mr. R. W. Vawdrey, "Reinforced Concrete." (Lecture I.)

Economics and Political Science, London School of, Clare Market, Kingsway, W.C., 8 p.m. Mr. W. M. Geldart, "Legal Powers and Limitations of Trades Unions."

TUESDAY, MAY 2...Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. George Paish, "Savings and the Social Welfare."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. J. E. C. Bodley, "The Decay of Idealism in France and of Tradition in England."

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Economics and Political Science, London School of, Clare Market, Kingsway, W.C., 8 p.m. Mr. J. H. Morgan, "The Legal Liability of the Executive."

Faraday Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. 1. Mr. A. Scott-Hansen (Christiania), "Hydro-Electric Plants in Norway and their Application to Electrochemical Industry." 2. Mr. Verdon Cutts, "Electro-Metallurgy in the Steel Foundry." 3. Mr. Edgar Stansfield, "Two Simple Forms of Gas-Pressure Regulators."

WEDNESDAY, MAY 3...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. A. W. Gattie, "Improvements in the Transport and Distribution of Goods in London."

Public Analysts, at the Chemical Society's Rooms, Burlington House, W., 8 p.m. 1. Messrs. J. C. Umney and C. T. Bennett, "The Evaluation of Certain Spices used in Medicine." 2. Mr. Edward Halliwell, "Absorption of Dissolved Oxygen by Sewage Effluents and the Royal Commission's Provisional Standard." 3. Dr. G. D. Lander and Mr. A. E. Walden, "The Detection of Traces of Hydrogen Cyanide." 4. Messrs. A. E. Parkes and J. D. Roberts, "Note on the Composition of 'Blaud's Pills'"; "Note on the 'Pearl Coating' of Pills." 5. Mr. J. F. H. Gilbard, "A reaction for 'Caulophyllin.'"

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Miss E. K. Prideaux, "The Sculptured Figures on the West Front of Exeter Cathedral Church."

Economics and Political Science, London School of, Clare Market, Kingsway, W.C., 5 p.m. Sir John Cockburn, "The Referendum in Australia."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.45 p.m. Mr. R. W. Vawdrey, "Reinforced Concrete." (Lecture II.)

THURSDAY, MAY 4...Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. The Rev. T. R. R. Stebbing, "On John Vaughan Thompson and his Polyzoa, and on *Vaunthompsonia*, a genus of Sympoda." 2. Professor Sydney J. Hickson, "On *Polytrema* and some allied genera." 3. Mr. J. M. Brown, "Observations on some new and little-known British Rhizopods. 4. Mr. R. All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 8TH, 8 p.m. (Cantor Lecture.) ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." (Lecture II.)

TUESDAY, MAY 9TH, 4.30 p.m. (Colonial Section.) F. WILLIAMS TAYLOR, London Manager of the Bank of Montreal, "Canada and Canadian Banking." His Grace the DUKE OF ARGYLL, K.T., G.C.M.G., G.C.V.O., will preside.

WEDNESDAY, MAY 10TH, 8 p.m. (Ordinary Meeting.) HAL WILLIAMS, M.I.Mech.E., M.I.E.E., "Beet-Sugar Factories." The EARL OF DENBIGH, C.V.O., will preside.

CANTOR LECTURE.

On Monday Evening, May 1st, Dr. ALFRED E. H. TUTTON, M.A., F.R.S., delivered the first lecture of his course on "Rock Crystal: its Structure and Uses."

The lectures will be published in the *Journal* during the summer recess.

LIST OF MEMBERS.

The new edition of the List of Members of the Society is now ready, and can be obtained by Members on application to the Secretary.

CONVERSAZIONE.

The Society's Conversazione will be held, by permission of the Trustees of the British Museum, in the Galleries of the Natural History Museum, South Kensington, on Tuesday Evening, May 30th, from 9 p.m. to 12.

The Reception, by Sir JOHN CAMERON LAMB, C.B., C.M.G., Chairman, and the other Members of the Council, will be held in the Central Hall from 9 to 10 p.m.

A Selection of Music will be performed by the Band of H.M. Royal Artillery, in the Central Hall, commencing at 9 o'clock.

A Vocal and Instrumental Concert will be given in the Fish Gallery and a Miscellaneous Entertainment in the Shell Gallery, under the direction of Mr. PATRICK KIRWAN, commencing at 9.30 p.m.

The following portions of the Museum will be open:—

The Central Hall, containing cases of specimens illustrating Mimicry; Adaptation of Colour to surrounding conditions; Protective Resemblance; etc. Also specimens illustrating the Food of Fishes, and the Life History of the Eel (East of staircase).

The North Hall, containing the collection of Domesticated Animals.

The Bird Gallery, containing groups of British Birds and Nests; and in the Pavilion, at the West end, an exhibition of the Land and Fresh-water Vertebrate Animals of the British Isles.

The Fish Gallery, containing the Great Basking Shark, the grotesque Deep-sea Fishes (case 44), the Tunny (case 38), the Tarpon and Angler-fish (case 27), and the Lemon-Sole (case 30), etc.

The Shell Gallery, including a life-size model of a Giant Squid (Newfoundland), and of a Giant Octopus (California).

The East and West Corridors on the First Floor, containing the Okapi, African Antelopes, and Giraffes.

Light Refreshments will be supplied at Buffets in the North and South Corridors on the First Floor of the Museum.

Visitors travelling by the District Railway (or other underground railways in connection therewith) will be allowed free use of the company's subway, which leads from South Kensington Station direct into the grounds of the Museum.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. (These cards will be issued shortly.) In addition to this, a limited number of Tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5s. each, if purchased before the day of the Conversazione. On that day the price will be raised to 7s. 6d.

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the Offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

It will greatly facilitate the arrangements if members requiring additional tickets will apply for them at as early a date as convenient.

The Council reserve the right of stopping the sale of tickets or of raising the price, if it is found necessary, in order to restrict the number of visitors within reasonable limits.

Further particulars as to the musical and other arrangements will be given in the Programmes, which will be distributed on the evening.

PROCEEDINGS OF THE SOCIETY.

NINETEENTH ORDINARY MEETING.

Wednesday, May 3rd, 1911; JAMES SWINBURNE, F.R.S., M.Inst.C.E., Past-President Inst.E.E., in the chair.

The following candidate was proposed for election as a member of the Society:—

Beg, Mirza Faiz Husain, Kothi M. Abbas Beg, Kaiserbagh, Lucknow, Oudh, India.

The following candidates were balloted for and duly elected members of the Society:—

Cope, Thomas, 27, Rosenthal-road, Catford, S.E.

Das, J. N., F.R.G.S., M.R.A.S., Khalispur H. E. School, Khulna, Bengal, India.

Gibson, Captain R. R., Immigration Office, Essequibo, British Guiana.

Giveen, Richard Lockwood, Colet-court, Hammersmith-road, W.

The paper read was—

IMPROVEMENTS IN THE TRANSPORT AND DISTRIBUTION OF GOODS IN LONDON.

By A. W. GATTIE.

Sir Alexander Henderson, the Chairman of the Great Central Railway, stated eight years ago, in an address to his shareholders, that if overlapping in goods traffic in London could be avoided by a combination of only six of the railway companies coming into London, a saving of a considerable portion of £2,500,000 a year could be made by those railway companies. (See Appendix D.)

I have not Sir Alexander's figures before me, and I am, therefore, unable to tell you how this estimate was arrived at, but I have myself investigated this matter very closely, and I have come to the conclusion that if the work of goods handling and cartage in London were done on scientific lines, a gross saving to the community of at least £20,000,000 a year could be made in London alone.

Everything that applies to London would, of course, apply in varying degrees to our other densely-populated centres, and I am quite sure that I am within the mark in stating that an economy well within the reach of science can be made which would effect an annual saving of an amount more than equal to the entire government revenue of the United Kingdom. With such a statement before you, you will at once recognise that economy in transport is not a matter of interest to any group or groups, but is one of vital importance to every man, woman, and child. The cost of transport enters into the price of everything, and therefore must affect every producer and every consumer. This fact is apt to be lost sight of, because, if a man goes into a cheesemonger's shop to buy a pound of cheese, the cheesemonger tells him the price of that pound of cheese is 1s., and in due course the cheesemonger sends it round to the house of the purchaser, and makes no charge for delivery. As a matter of fact, however, the cheesemonger has charged so much for the cheese and so much for transport. It may surprise some people to know that while transport in the matter of some things is a very small percentage of the cost, yet in others it is a very high percentage. If we may take, as an important item, such a thing as wheat, we find that in 1868 the cost of conveying a quarter of wheat from Chicago to Liverpool was 11s. 6½d., whereas at the present moment it is 2s. 10½d., and you will see that in this one

important item a saving of 8s. 8d. has been made out of 11s. 6½d. This saving is due to improvements in means of transport. If a sum of 8s. 8d. can be saved in the transport of one quarter of corn, it is sufficiently obvious that by multiplying this figure by some millions, we may easily arrive at a very large sum. You will, therefore, see that by an economy analogous to the one I have already quoted, a saving of £200,000,000 a year is by no means out of the question.

The enormous saving which has been made in water-borne transport during the last forty years has been effected by improvements in machinery and by the economic system of management of shipping companies. This economic system of management, and the encouragement which has been given to marine engineers to improve their methods, is due to the fact that steamship companies have had to compete with one another; but in the matter of land transport, while there has been a certain competition between the bureaucracies governing railway companies, it has been a restricted competition of not the most healthy kind.

I must not be understood to say that the efficiency of the locomotive has not been improved; it has been enormously improved. Since the year 1850 it is interesting to know that the tractive power of passenger locomotives has increased 83 per cent., and the tractive power of goods locomotives has increased 97 per cent.; but despite the splendid results achieved by the locomotive engineers, goods transport has not improved. That means that the whole of the 97 per cent. improvement made by the locomotive engineer has been frittered away in bad management at terminals. Let us be under no misapprehension as to why goods transport in this country has remained the most expensive in the world. There are only two factors of cost—hauling and handling.

I have shown you in exact terms that the tractive power of the goods engine has almost been doubled; but, unfortunately, all the economies achieved on the track are squandered in the hideous waste of our terminal arrangements.

In an address to the London Chamber of Commerce last June, I promulgated the adoption of the principle of the Bankers' Clearing House to the business of transport. I showed how great a benefit the Clearing House has been to the banker, and I believe I succeeded in proving, by analogy, that it would be a benefit as great, or even greater, in the matter of transport.

The Bankers' Clearing House is a place where certain pieces of paper called cheques are collected and redistributed.

A Goods Clearing House is a place where truckloads of general merchandise, goods, bales of goods, and parcels, could be collected and redistributed. By general merchandise I mean practically everything except coals and cattle. In the Bankers' Clearing House pieces of paper called cheques pass from the hand of one clerk to the hand of another clerk, and the transference is completed. A clerk distributing a portmanteau full of cheques at the Clearing House might, by moving only a few yards, distribute parcels of cheques to twenty or thirty other clerks in less than a minute; but before the Bankers' Clearing House was established, that clerk would have had to walk round the whole of the City and call at twenty or thirty banks, a tour which would probably take him an hour or more. Thus it will be seen that out of sixty minutes, fifty-nine have been saved, and this saving applies to every bank admitted into the Clearing House.

Now for the analogy. Instead of the word "banker" let us use the word railway, or carrier, or trader. Instead of a portmanteau and a bundle of cheques, we will substitute a railway wagon, or a motor-van, and a load of bales, which may, perhaps, weigh three tons. It is, of course, quite easy for one man to hand to another a handful of pieces of paper, but in order to handle heavy weights rapidly and without concussion, modern apparatus is absolutely necessary. Therefore, instead of clerks, I propose to equip the Goods Clearing House with apparatus suitable for the purpose.

At the present moment I only wish to invite your attention to the enormous economy to the railway companies which would be effected by the adoption of this Bankers' Clearing House system, because it provides a place where railway companies can exchange loads with one another without shunting or marshalling, and consequently without the necessity of the enormous shunting yards which they now use. It is no exaggeration to say that these goods stations and shunting yards are, figuratively, bottomless lakes into which railway managers are throwing their shareholders' money, and the money of the community, by the sackful. But this is not merely a question of railway

economy; it is also a question, and an equally important and pressing question, of economy of van traffic in London streets. All traffic between goods stations would necessarily disappear, as the business could be done in one place; but, more than that, it is quite clear that both in taking goods to consignees and carrying them from consignors one vehicle only would be necessary where a great number are now used.

In the Address to the Chamber of Commerce above referred to, I drew particular attention to the existing condition of street traffic in London. Summarising my statement on that occasion, I showed that at least twenty vans were used to do work which on co-operative and organised lines might be done by one, and, turning to the use made of the railway wagon, I showed that even a worse state of things prevailed.

The life of a railway goods wagon is about seventeen years, and during that seventeen years it is only mobile on the track for six months—in other words, for sixteen and a half years out of seventeen that wagon is detained in loading, unloading, and shunting, and, as a consequence of the shunting, undergoing repair. This goods wagon may cost anything from £70 to £100, and the cost of keeping it in repair, at a very moderate estimate, would be £4 a year.

Well, if this goods wagon is standing for sixteen and a half years, it must be standing somewhere, and it is very often standing uselessly rotting in sunlight and rain on a very expensive piece of land. If you will look at the map on the wall, you will see I have marked the sites of these standing-places in red, and to enable you to form some idea of the large area they cover, I have coloured Hyde Park, St. James's Park, and various other parks in green.

With such figures, and such a map before you, you will, I think, realise that there is room for much improvement. It is quite clear that if, instead of using a railway goods truck for half-an-hour out of twenty-four hours, it could be used for a whole hour out of twenty-four hours, only half the number of wagons would be required to do the work, and only half the standing-place required to berth them.

Now railway companies own about 766,000 wagons, and these, at a low computation, must be at least worth £50,000,000. These wagons have to be renewed every seventeen or eighteen years at vast capital outlay, not to speak of maintenance. They are not worn out in use; they are worn out in disuse, and misuse. By the latter I mean the process known as shunting, which consists in bringing the vehicles into violent collision with one another. This process is dangerous to human life, it is damaging to railway property, and it is uneconomic, unscientific, and abominable from every point of view. It may be as well to explain by an example what shunting means, and why, under existing circumstances, it is necessary.

For instance, a goods train leaves Bristol for London, and it carries a number of wagons with what is called "through traffic," or traffic for other railways. On arrival at the shunting-yard at Willesden, called Old Oak Common, it will be necessary to split that train up into sections, and to push the various sections into sidings, one or more wagons going into each siding, each siding being set aside for a particular railway company.

Let us assume that one of these railway wagons was shunted into a siding, and is destined to go to a station on the London, Brighton and South Coast Railway. This wagon will not necessarily be immediately moved from Old Oak Common; it will wait in the siding into which it has been shunted, and after some hours this siding will get full of other wagons, also for the London, Brighton and South Coast Railway. Having waited, perhaps, six hours, and endured much banging, a Great Western engine will haul it, together with some thirty other trucks, to a shunting-yard called Lillie Bridge, at Brompton. It will be noticed that these supposed thirty or thirty-five trucks from the Great Western would be in no particular or desired order. They will simply be taken by the Great Western to the Brighton Railway at Lillie Bridge without any sorting whatever having been done, and without any sorting whatever being possible. At Lillie Bridge the process of marshalling will take place. The wagons in marshalling are picked up and dropped, and picked up and dropped, and banged together again, hour by hour, at Lillie Bridge, until the various goods trains on the Brighton system are made up in the proper order, and depart on their journeys.

I cannot help thinking that if these processes of shunting and marshalling were to give way to a scientific and economic substitute, everybody, railway companies, traders, and the community at large, would greatly benefit. Let us see how, with suitably

designed apparatus, it would be possible to deal with the train from Bristol I have already instanced.

According to the proposed Goods Clearing House regulations, all trains coming into it would be loaded in such a way as to permit of their burdens being lifted off the vehicles by cranes; these cranes would be of a special pattern, and capable of moving loads through all three dimensions of space. In this way the load of goods I have instanced as being shunted at Old Oak Common, and then carried to Lillie Bridge and marshalled, would go through none of these processes. The train would arrive at the Clearing House, and the load would be lifted from the Great Western train and put on to the Brighton train, if the Brighton train were there to receive it. If the Brighton train were not there to receive it, it would be put in an appointed place in the Clearing House, and would wait until the Brighton train was there to receive it, and it would then be placed in its right position on the Brighton train. In this very simple way this substitute for the work of shunting could be done at, I believe, 1 per cent. of the present cost in time, space, and labour.

The Goods Clearing House, however, would not confine itself to the mere transference of heavy loads. It would also be equipped for the rapid sorting of goods and making up of loads, and this work could be carried out at a speed of something like 2,000 bales a minute. I propose to go into this matter in further detail later on.

Nearly a year has lapsed since the delivery of my speech at the London Chamber of Commerce, and although it has been given the very utmost publicity in the daily press, and in newspapers varying in character from the *Drapers' Record* to the *Lancet*, and in a great number of technical papers of high standing, no one has accepted my invitation to amend the figures I then put forward. I have, however, been asked many questions, and one very persistently. How is it, it has been asked, if so great a benefit can be conferred on railway companies by your proposed reforms, that railway managers do not receive you with open arms? The directors of my company have been quite as puzzled on this subject as our questioners, and in order to clear the matter up, and enable me to give you some definite information on the point, we last month addressed the following letter to all the general managers and goods managers of the railway companies running into London:—

"Dear Sir,—The general managers of two railway companies coming into London have expressed the opinion that the project put forward by this company of establishing a Central Goods Clearing House in London is 'impracticable.'

"The directors of this company naturally attach considerable importance to this expression of opinion, and are, therefore, anxious to learn whether you endorse it.

"If that is the case, may we inquire whether you claim that the alleged impracticability consists in any of the following details:—

"1. The proposed electrical arrangements.

"2. The proposed mechanical arrangements.

"3. The proposed structural arrangements, and, if so, whether in the matter of the proposed approaches or in the structure and design of the building itself.

"4. The proposed system of sorting parcels, bales, or heavy loads of goods by automatic conveyors.

"5. The proposed clerical arrangements.

"6. The proposed arrangements for elimination of shunting and marshalling.

"7. The proposed arrangements for the manipulation of traffic.

"8. The proposed financial arrangements, and, if so, in what specific direction.

"Failing the discovery of any impracticability in the foregoing features, would you so far indulge us to let us know in what shape, form or function you discover the alleged impracticability?

"We should be very much indebted to you if you can see your way to do this, as we feel that the opinion expressed by the two general managers referred to must be due to a misconception or want of detailed information as to the proposals actually put forward by this company.

"We shall have much pleasure in answering any question you care to put to us, or in clearing up any point of objection if made in a specific form.

"Under separate cover we are sending you a copy of our chairman's address to the London Chamber of Commerce last June.

"The subject will be further discussed on the 3rd of May next at the Royal Society of Arts, and any railway gentleman will be, we know, heartily welcomed by that Society.

"Awaiting the favour of your reply,
"We are, Dear Sir,
"Yours faithfully,
"THE NEW TRANSPORT COMPANY, LTD."

I have received a variety of replies from the railway companies, but not one will give any endorsement to the opinion of the two general managers, who, without the remotest knowledge of any of the apparatus it is proposed to

employ, expressed the opinion that the project was "impracticable."

There are, however, two letters written from railway companies in which the writers confess themselves unable to offer an opinion, as they are without any detailed knowledge on the subject, and it is worthy of note that neither of these gentlemen expresses any anxiety to be enlightened. They do not say the scheme is "impracticable"; they merely say, under the conditions with which they are familiar, such a project would be impossible, and with this opinion, both I, and the group of distinguished engineers with whom I have the honour to be associated, are in full concurrence.

Without the necessary machinery, the Clearing House would be an impossibility.

In a conversation with one of the two general managers who have expressed the opinion of the "impracticability" of a goods clearing house, the question was raised as to how it would be possible to deal with the fish traffic coming in to London. This is one of the innumerable matters of detail which have to be dealt with in any proper consideration of this scheme. Vague generalities are worse than useless, and I am, therefore, going to take this subject which was selected by the railway manager, and explain it in unmistakable terms.

In reply to his inquiry I gave the following explanation :—

I told him that about 800 tons of fish arrive every day at Billingsgate, and of this 400 tons is water-borne, and 400 tons is carted from the various London goods stations by means of about 180 pair-horse railway vans. The bulk of these vans arrive at Billingsgate between three and four in the morning, and remain waiting in the precincts of the market for an average of over eight hours, when they depart, on their return journey to the railway stations whence they came, with loads of empty and very malodorous fish trunks. Owing to the presence of these vans during the long hours of their detention, retailers' carts are unable to come close up to the market place, and that disability involves the necessity of expensive porterage. I may here say that these porters who carry the fish trunks on their heads may earn as much as £3 a week. The disadvantages of such a state of things are quite obvious. I explained to this general manager that my proposal was that all fish trains, or all railway wagons carrying fish, should proceed to the Clearing House, and thence proceed to the proposed Clearing House wharf, *via* Snow Hill railway connection, as shown on the map in front of you.

You see that the wharf is situated between the railway bridge and the road bridge at Blackfriars, on the north bank of the river, and is only a two-minutes' run by rail from the Clearing House. The fish so conveyed would be packed either in trunks or in bulk, in suitable steel cage containers of about eight to ten tons capacity, and detachable from the railway wagons. On arriving at the wharf, these cages or containers would be lifted from the railway wagons by the cranes and lowered into specially designed fish barges, each of which would carry about 100 tons, and would be equipped with a view to facile unloading on arrival at Billingsgate. These barges would be reserved exclusively for this service, and on their return journey would bring away from Billingsgate all empty fish trunks in the returned containers. On arrival at the wharf on this return journey, the containers which brought the fish of the previous day would now be hoisted from the barges with their load of empties and dipped into a deodorising tank by the crane. The crane would then unload the newly-arrived fish from the railway wagon and place it in the barge, and would then load up with the cage of empty trunks for the return journey.

It will be seen that in this simple way London street traffic would be relieved of two journeys by 180 wagons and 360 horses. At the same time a great economy would be effected, because the loading up of the fish boxes at the goods station and the unloading of them on arrival at Billingsgate would be done away with, and the loading up of the empties into the vans and the unloading of them again at the goods station on the return journey would also be done away with. In addition to this great advantage, there would be the saving in space, and the retail fishmonger would be able to get near to the market place, which would no longer be blocked with the unnecessary vans.

The general manager in question was unable to see any advantage in the proposed method, which he declared to be impossible. I have, however, communicated with the Fishmongers' Hall, and have received an intimation that the matter will be considered at the next meeting of their council.

In considering the attitude of railway managers towards the Clearing House scheme, two important factors must not be lost sight of. The one is the immense force of habit of mind

and the other is the great progress which has been made in recent years in scientific apparatus. Railway managers are not men of science. The manager has been accustomed all his life to receive a goods train in London in the small hours of the morning, to have it unloaded clumsily, slowly, and arduously, by hand and hand-truck, and, having so unloaded it, to allow empty trains to cumber come fifty miles of sidings for about sixteen or seventeen hours, when some of these trucks are again loaded and despatched from London. We are all of us creatures of habit, more so than we realise, and the railway manager is no exception to the rule. Consequently he wants to know where we are going to store some 12,500 wagons for seventeen hours in the Clearing House. To store wagons in the Clearing House is utterly absurd and impossible; it has never been suggested, and it is by no means necessary. The necessity only exists in the mind of the railway manager.

Let us now see how this unnecessary waste of time, space, and rolling-stock can be avoided. Towards the end of the business day the clearing house would receive some thousands of tons of goods consigned to it by traders and manufacturers in London. The total amount of goods delivered by road during the whole day would probably amount to 25,000 tons, 15,000 tons of which would be for despatch by rail, and 10,000 for despatch by road. The greater quantity of the 15,000 tons would be received in the afternoon and evening, and would probably all be in hand by ten o'clock at night. By midnight the whole of these goods could be sorted and loaded up into containers. (Let me remind the audience, a container is a large box, or cage, or skip, designed to contain anything required.)

As soon after twelve o'clock as can be arranged, goods trains loaded with goods from every part of the country might begin to arrive at the Clearing House in ever-increasing numbers, hour after hour.

There are twenty-four working train berths in the Clearing House; each of these berths is 1,300 feet long, and therefore capable of receiving a train of about that length, if called upon to do so. These twenty-four berths are overhung and served by 240 electric travelling cranes, each crane being capable of hoisting five tons at a time. There are also six supplementary berths only accessible to the road level cranes. The arriving trains would be so loaded that their contents could be seized by these cranes and immediately hoisted into the Clearing House. Supposing that the cranes installed were able to work as rapidly as the steam crane now in use on Folkestone Pier, which every day hoists containers from the Channel steamers on to the railway wagons on the quay, we should be able to make a little more than one hoist per minute per crane. Our maximum hoisting capacity in the Clearing House would be, therefore, 240 loads per minute. Assuming that each load was about two tons, this gives us in round figures an unloading capacity of about 500 tons per minute. Having unloaded a train, the next thing to do would be to reload it from the store of goods already in the Clearing House and despatch it with as little delay as possible. It will thus be seen that trains arriving in the Clearing House can be unloaded and reloaded at a speed which is now utterly undreamt of by our friends the railway managers.

On Folkestone Pier they have themselves proved what can be done, but they have not learnt the lesson they have taught.

We will now consider in detail how trains might arrive at the Clearing House.

If you will look at the map before you, you will see there are three pairs of tubes, one going to the north, and serving a group of huge goods stations marked in red immediately above King's Cross. These goods stations are collectively about half a mile broad by three-quarters of a mile long, as nearly as I can measure it.

Another tube goes to the east and joins on to another enormous goods station, and a third goes south and links up the Clearing House, *viâ* Blackfriars railway bridge with South London, and it also links it with the River Thames, an avenue of approach by no means to be despised. It would present no difficulty whatever for trains to arrive at any of these three points, viz., King's Cross and St. Pancras, Bishopsgate, or Blackfriars, and to be there held for such number of minutes as might be convenient until the Clearing House was ready to receive them. A digest of the railway routes approaching the Goods Clearing House is printed in Appendix A., and eventually a time-table showing the hour of arrival and departure of each train will be drawn up.

At the present moment there are about 290 goods trains coming into London every day. It would be quite possible to receive these 290 trains through the three tubes shown. If each tube were to receive a train once in three minutes, the Clearing House would be supplied with one train a minute, and it could in the same

way despatch one train a minute, or one train by each tube at intervals of three minutes.

In this way it will be seen that the whole of the postulated traffic could be negotiated in 290 minutes, or less than five hours.

This is a considerable improvement on the methods in vogue. At one goods station where I have spent many hours in investigation, I find that by the hand and hand-truck method, 195 men were able to load 918 tons in seventeen and a quarter hours, the men working on eleven hour shifts.

I remind you here that Clearing-House speed can load up 500 tons a minute. It will, therefore, be seen that Clearing House loading speed is, as nearly as possible, 500 times as great as goods station speed.

I trust that what I have said will show that when the two railway managers said the scheme was impracticable, it was probably because they did not understand the possibilities created by the introduction of modern machinery into the matter of goods handling.

I think it is now clear how a speed such as I claim for Clearing House methods will easily account for the fact that the Clearing House would be able to do the entire work not only of the seventy-two goods stations, the larger of which you see marked in red on the map before you, but also of a very much greater number of receiving depots and carriers' yards, all of which are of the old-fashioned "ramshackle" type.

I remember on one occasion visiting the premises of one of our most important carriers, and I saw a man coming upstairs with a bale of goods on his back. I have never forgotten it.

I will now ask you to look at this diagram, which represents one of the great sorting floors in the Clearing House; this sorting floor is about as large as Lord's cricket ground, and the one above it, and just like it, is also about as large as Lord's cricket ground. These two floors are overhung by cranes; these cranes hoist container loads of goods from the railway beneath, or from the roadway beneath. The roadways consist of thirteen bridges running east and west, and these bridges span the railway tracks beneath, which run north and south. The bridges are each fifty feet wide and fifty feet apart from each other, thus leaving a gap or void between them, so that a crane can hoist a load through the numerous wells or hatches either from the road or from the rail. Having so hoisted a load from either one or the other into the sorting room, the crane, which can move loads in all three dimensions of space, deposits its burden on to the required bay or sorting deck. When a container is thus deposited on the floor of the sorting room, it is opened either at the back or the sides or top, and the contents are removed, and checked against a list in the usual manner. The separate packages of which the load consists are now put on to steel trays which run at each side of the bay, and are shown on the diagram marked R D. These trays move at the will of the man in charge of that particular sorting deck. When a tray in moving from the point R to the point D reaches the point D, a man called the distributor reads the address on the parcels with which the tray is loaded. Supposing he sees that the parcel (or parcels) is directed to Manchester, he knows that the number of the Manchester bay is, say, 123. He would strike the appropriate keys on the instrument before him, and depress his starting-switch. Nothing would happen as a consequence of this, until a disengaged section of this travelling platform reached an exact point. The arrival of this disengaged section at an exact point would complete certain electric circuits energising a pair of roller magnets fixed at the despatching point, and also a similar pair of roller magnets fixed on the conveyor section. These two pairs of rollers would rotate synchronously, that is to say, they would rotate at the same speed. Now the property of these roller magnets is interesting. The effect of magnetising anything is to make it sticky. The stickiness of the magnets in question is something in the nature of a quarter of a ton, but although these magnets stick to the bottom of the tray, and will not let it slip from them, yet they can be easily rotated, and will roll on the under-surface or bottom of the tray quite freely. Thus when these magnets begin to rotate, they drive the tray forward in a given direction and at a uniform acceleration. When the tray, being despatched, has got midway between the despatching point and the moving platform, it is travelling at its highest speed. The despatching magnets release it at this point, and the receiving magnets on the moving platform seize it, and, by continuing their rotation, bring it into a central position on the moving surface of the section. At this moment they come to a halt, they drop downwards, and in so dropping thrust two cone-shaped bolts into the bottom of the tray, thus fixing it to the conveyor. On arriving at the predetermined point, which we have called 123, these roller magnets are again energised. They rise in their bearings, and in so rising they withdraw the bolts, unfastening the

tray from the conveyor, and by a synchronous rotation discharge the tray on to a receiving point, which is also fitted with a pair of similar magnets.

The foregoing would be a very simple operation, but it would not be sufficient for Clearing House purposes. It would be constantly necessary for bales, crates, and parcels to pass from one end of the Clearing House to the other, or from one floor of the Clearing House to the other.

You will note from this plan that the floors of the sorting-rooms are veined by what I have previously called magnetic rivers. Not only could a tray be conveyed from one point to another on the same magnetic river in the way I have just described, but more than this can be done, much more. You will see there are six divisional conveyors or belts, which are numbered one to six and coloured green on the plan; and running inside the wall of the building, all the way round, you will see there is another very big conveyor coloured red; that big conveyor I call the main belt; it links up all the six divisional belts. On the inner side of it you see it runs in parallel contact with the ends of the divisional belts. On its outer edge you will notice it runs in parallel contact with another belt. This other belt is called the dipping belt, coloured purple; perhaps I shall best describe it by calling it a loop belt. There are ten of these belts. They journey from the sorting floor below to the sorting floor above, and down again to the sorting floor below. They are placed all the way round the building, and act as connecting links between the two main belts.

Now a feature of the Clearing House system is, that a bale of goods can be placed on a tray, and the operator having struck the necessary keys on his despatching instrument and depressed his starting-switch, the tray will start on its journey; that journey might involve the following transfers before reaching the predetermined destination. Supposing that the despatch point were at the north end of the Clearing House, and the receiving point were at the south end, *and* on the floor above, the route would be as follows:—

The tray would travel in this direction until it reached the main belt. This main belt goes at double the speed of the divisional belt, and therefore main belt sections are constantly overtaking the divisional belt sections. On a disengaged main belt section coming into correspondence with an engaged divisional belt section, and the controlling apparatus on the divisional section permitting, a transfer of the tray would take place automatically from the divisional belt section to the main belt section. The main belt section would then have possession of the tray, and on coming into contact with the dipping belt section a little further on, the main belt section would re-transfer it to the dipping belt section. The dipping belt section would take it to the floor above, and in the same way as before transfer it to the main belt on the upper floor. The main belt on the upper floor would then carry it to the required divisional belt on that floor, and would deliver it to a disengaged section of that belt. The divisional belt on the upper floor would then carry it to the receiving point, where it would be delivered. The whole of these transfers are automatic, and are performed without any concussion. It will be noted that, together with the transfer of the tray, the original register set by the operator in the first instance is transmitted from one instrument to the other until the final directions are received on the receiving divisional belt. In fact, these instruments practically talk to each other.

I will now return to the less scientific side of the question.

We have postulated that it might be necessary for the clearing house to receive one train per minute at certain hours during the day. This would involve a large intake of goods in the sorting rooms, which would have to be dealt with very expeditiously.

Let us suppose that in a busy hour of the day 1,200 loads of miscellaneous articles need to be hoisted into the sorting rooms and there dealt with. If each load were to weigh two tons, that would amount to 2,400 tons. If all these bales and packages were small, the average weight might be half a hundredweight each. This would be an abnormally small lot, but in such a case the sorting room would be required to sort nearly 100,000 packages in the hour.

We know very well that without machinery it could not be done, but with the introduction of machinery all that is altered.

The first process of distribution is accomplished by the cranes which hoist the containers into the sorting room, each container being placed in its appointed position. These containers have to be opened and their miscellaneous contents distributed all over the two floors, so that each package can reach its appointed place. The items are removed from the containers in which they arrive, are checked in the usual manner against a list, and the

porters place them on any of the adjacent trays.

Let us suppose that in this busy time of the day we employ 2,000 of these porters. I think you will agree that without particularly exerting himself, each porter during the hour could manage to take fifty parcels out of a container and put them on to a tray, and to remove fifty parcels from a tray and put them into a container—that is to say, that each porter would be called upon to handle 100 parcels in an hour—that is to say, each porter has to read an address and move a parcel either by hand or by means of a pneumatic hoist, from a container to a tray, or *vice versâ*, the distance between the tray and the container being three feet or four feet perhaps. Half a minute does not sound a very long time, but I think that if I were to pause in speaking to you for half a minute in search of a word, you will find it a very long time indeed. I am perfectly certain that the time I am here allowing is ample, because it is five times as long as the sorters at the Parcels Post Office, Clerkenwell, take to do the same work, i.e., handle a parcel.

With regard to the rate at which these trays, each carrying one parcel or more, can be distributed, you will see by the plan that there are some 216 distributing points. Supposing the Clearing House to be working at full shift, and supposing that each of these men were to despatch about five trays a minute, you will see that our speed of sorting would be about 1,000 trays a minute, and, as I said before, these trays would carry one, two, or more parcels apiece.

I think I have now indicated the speed capacity of the Clearing House, and when we come to compare a performance of this description with the system at present in vogue, I think it will be agreed that the new plan is an improvement.

By the hand and hand-truck method, even granting the floor space I have specified, the work done by 2,000 men rushing about the Clearing House with hand trucks is a spectacle of chaos, before which one's imagination absolutely quails. Let these men work as hard as they like, it would be difficult for a man to make more than five or six hand-truck journeys in the course of an hour; but with only 10 per cent. of these men, each standing at the distributor's desk and striking the keys and depressing the switch, I see no difficulty in their performing this duty in one minute or less. We all of us know the condition of a railway platform on the arrival of a heavy train from the Continent, and the scrimmage which takes place in order to get our luggage on to our cab. That gives a very good idea of the present system of sorting goods at a goods station by hand. I think it is best described by the word "scrimmage."

Scientifically speaking, the difficulty lies in the conflicting lines of traffic on the goods station platform. In the Clearing House there are no conflicting lines of traffic; the platforms are only four feet wide as against the fifty feet wide platform of the goods station, and yet, though less than one-twelfth of the width of the latter, the Clearing House moving platform can do twenty times the amount of work; but whether the speed of the Clearing House is ten times as great, is not of immediate moment. The question of importance is whether machinery is better for our purpose than hand and hand-truck methods, and, if so, what are the reasons for opposing its adoption.

We will now turn our attention to the question of cartage of goods by road to and from the clearing house, and we will see how rapid loading and unloading of vehicles affects the question.

Under existing circumstances, a carrier's van, or railway van, will usually spend eight hours a day out of an available twelve to sixteen in loading and unloading at the depot. If this eight hours spent in loading and unloading can be reduced to something less than half an hour, it is clear that this van would have seven and a half hours more time available for doing work. This reform alone would admit of one van doing the work of three, but there are many other economies to be effected by the adoption of the Clearing House system.

Let us now consider what would be the number of vans requisite to do a day's work to and from the Clearing House in the administrative county of London.

To begin with, there are 634,110 houses (occupied or unoccupied) in this area. We will suppose it to be necessary to visit about one house in ten every day—that is to say, we will suppose that a day's work will consist of visiting 63,000 houses of all sorts and kinds; some of these houses will be private, and others will be business houses. Some houses it would be requisite to visit many times, and others only once, either to collect or deliver goods. It must be borne in mind that we are now considering slow-going van traffic, and in this category we of course do not include the rapid cart of the butcher and the baker and other local tradesmen.

Let us suppose that in dealing with the 63,000 houses we propose to visit, either to collect or deliver goods, we make the following calls :—

Number of Houses.	Number of Times Visited.	Total Visits.
20,000	1	20,000
15,000	2	30,000
10,000	3	30,000
5,000	4	20,000
4,000	5	20,000
3,000	6	18,000
3,000	7	21,000
2,000	10	20,000
1,000	20	20,000
20	50	1,000
63,020		200,000

We will now consider what the visiting capacity of a Clearing House car might be in, let us say, twelve hours.

Let us assume that each car makes 100 visits a day, each visit occupying five minutes. This would give us 500 minutes, or eight hours and twenty minutes out of the available twelve. This would allow us about three hours and twenty minutes on the road, and leave a total of twenty minutes spent in the Clearing House loading and unloading. With a running time of three hours odd at eight miles an hour, each car could perform an average of four journeys to and from the Clearing House, each journey being an average of three miles out and three miles in. In order to call on the 63,000 houses necessary, and make the requisite 200,000 visits during the day, we should, of course, require 2,000 cars to do the work.

I do not say that this estimate is correct, or approximately correct, as regards actual requirements ; I merely say that supposing the work to be what I have indicated, it could be done by 2,000 cars. The actual number of slow-going vans now employed on the London streets, either privately owned, or owned by the railway companies or the carriers, is not known, but the Midland Railway have admitted that they have 1,000 of these vehicles in use on the London streets, and if this may be taken as any criterion of the number of road wagons employed by the other railway companies in London, we must needs multiply this figure by at least ten. This would give us a total of 10,000 railway wagons in use on the streets of London, and as a matter of fact we have almost an equal number of carriers' vans, as will be seen by reference to Appendix C.

So long as the railway managers withhold the necessary information, so long, of course, we are deprived of the advantage of investigating the subject in the light of exact figures. Why railway managers object to investigation, I do do not know. I should be glad to know. If railway managers will tell us the exact amount of collection and delivery work that has to be done, together with full details, we shall be able to make a closer estimate. It must be remembered that railway arrangements, as at present devised, tend to force all the work into a few hours, whereas Clearing House arrangements, as proved in practice in the Bankers' Clearing House, tend to spread it over the whole day.

The question whether the traffic of London streets would be perceptibly relieved if this work of collèction and delivery were done by 2,000 cars, or even 4,000 cars, is best answered by reminding you that the mileage of London streets is, according to the London County Council published statistics, 2,192 miles. Therefore, if 4,000 cars, double the number I have postulated, were distributed over these streets, there would be one car to every half mile of streets. On the other hand, under existing conditions, on the basis of the Midland Railway admission, we must assume that the number of railway vans only on the streets of London is, in round figures, 10,000. I simply use this estimate as a basis of calculation, and I leave the railway managers, who have access to exact sources of information, to correct me. My argument, however, will not be shaken by any possible amendment, as will be seen. Certain special counts of vehicles have been made by the expert advisers of the New Transport Company, Limited, and the results will be found in Appendix C., previously mentioned. Reference to this Appendix shows that nearly half the street traffic of London consists of goods vehicles. The classified enumeration shows that railway vans form more than a quarter of the total of goods vehicles in use, and carriers' vans over one-sixth. If the number of railway vans is 10,000, more or less, the total trade vehicles must be put at 40,000, more or less.

I have shown you what an organised service of 2,000 cars might be reasonably expected to do, and if we go so far as to double that number, that would only be 10 per cent. of the vehicles now blocking the streets of London to the unnecessary and avoidable detriment of everybody using the thoroughfares. This is my answer to the question that has been put to me: "How would the Clearing House relieve the congested condition of the streets of London?"

I shall be very grateful to any member of the audience who will be so kind as to amend any figure I have advanced.

APPENDIX A.

DIGEST OF ROUTES.

FROM THE VARIOUS RAILWAY SYSTEMS TO THE PROPOSED GOODS CLEARING HOUSE.

Prepared for the New Transport Company, Limited, Bath House, Holborn Viaduct, E.C.

By VERNON R. M. GATTIE.

Introductory Note.

The routes here given are classified under three headings —

Main Routes,
Subsidiary Routes,
and Emergency Routes.

The main routes are those routes which a train would naturally take—distinguished by directness and continuance over the same system, where possible. It will thus be found that each system has one, or at most two main routes to the Clearing House.

The subsidiary routes are those routes which might with advantage be employed in the event of the main route becoming unduly congested at any period, or in the event of a temporary stoppage of the main route. In most cases, the distance over the subsidiary route is not much longer than that over the main route.

The emergency routes are those routes which, by reason of their devious nature or unfavourable road or gradients, would only be employed in the event of an accident on the main and subsidiary routes.

In some cases, no subsidiary routes are given. This is where there is no route beyond the main route which could with any advantage be mployed except in the event of accident.

Where no emergency routes are given, it is because they are too devious to be within the range of practical utility.

GREAT NORTHERN RAILWAY.

All lines run to Finsbury Park.

Main Route.

Route 1.—*Via* Finsbury Park and King's Cross.

Subsidiary Route.

Route 2.—*Via* Finsbury Park, to N. London Railway, Canonbury, Dalston Junction and Broad Street.

MIDLAND RAILWAY.

All lines run to Hendon.

Main Route.

Route 1.—*Via* West Hampstead, Kentish Town, and St. Pancras.

Subsidiary Route.

Route 2.—To Metropolitan Railway, Finchley Road, Baker Street, and King's Cross. (This route only by shunting.)

Emergency Routes.

Route 3.—*Via* West Hampstead, to Tottenham and Hampstead Junction Railway, South Tottenham, to G.E. Railway, Clapton Junction, Hackney Downs, and Bishopsgate.

Route 4.—To N. & S.W. Junction Joint Railway, Acton Wells Junction, South Acton, to L. & S.W. Railway, Clapham Junction, to S.E. & C. Railway, Loughborough Junction, and Snow Hill.

Route 5.—To N. & S.W. Junction Joint Railway, Acton Wells Junction, South Acton, to L. & S.W. Railway, Grove Road, to Hammersmith & City Joint Railway, Westbourne Park, to G.W. Railway, Bishop's Road, to Metropolitan Railway, Baker Street, and King's Cross.

LONDON AND NORTH-WESTERN RAILWAY.

All lines run to Willesden Junction.

Main Route.

Route 1.—To N. London Railway, Camden Town, to Midland Railway, St. Pancras—

(*a*) *Via* Gospel Oak and Kentish Town.
(*b*) *Via* Chalk Farm.

Subsidiary Route.

Route 2.—To N. London Railway, Camden Town, Dalston Junction and Broad Street—

(*a*) *Via* Gospel Oak and Kentish Town.
(*b*) *Via* Chalk Farm.

Emergency Route.

Route 3.—To West London Joint Railway, Addison Road, to West London Extension Joint Railway, West Brompton, to S.E. & C. Railway, Loughborough Junction, and Snow Hill.

GREAT CENTRAL RAILWAY.

All lines run to Neasden.

Main Route.

Route 1.—To Metropolitan Railway, Finchley Road, Baker Street, and King's Cross.

Emergency Routes.

Route 2.—To Midland Railway, Acton Wells Junction, to N. & S.W. Junction Joint Railway, South Acton, to L. & S.W. Railway, Clapham Junction, to S.E. & C. Railway, Loughborough Junction, and Snow Hill.

Route 3.—To Midland Railway, Acton Wells Junction, to N. & S.W. Junction Joint Railway, South Acton, to L. & S.W. Railway, Grove Road, to Hammersmith and City Joint Railway, Westbourne Park, to G.W. Railway, Bishop's Road, to Metropolitan Railway, Baker Street, and King's Cross.

NOTE.—The line from High Wycombe can utilise Routes 2 and 3 above, and also all routes open to trains from the Great Western Railway.

GREAT WESTERN RAILWAY.

The two lines from Reading and from High Wycombe join by way of Greenford and Hanwell, so that all routes are interchangeable.

Main Route.

Route 1.—*Via* Ealing, Bishop's Road, to Metropolitan Railway, Baker Street, and King's Cross.

Subsidiary Route.

Route 2.—To N. London Railway, Camden Town, to Midland Railway, St. Pancras—

(*a*) *Via* Ealing, Acton Wells Junction, to N. & S.W. Junction Joint Railway to L. & N. W. Railway, Willesden Junction, Gospel Oak, and Kentish Town.

(*b*) *Via* Ealing, Acton Wells Junction to N. & S.W. Junction Joint Railway Willesden Junction, to L. & N.W. Railway, Chalk Farm.

Emergency Routes.

Route 3.—To N. London Railway, Camden Town, Dalston Junction, and Broad Street—

(*a*) As above Route 2 (*a*).

(*b*) As above, Route 2 (*b*).

Route 4.—*Via* Ealing, to West London Joint Railway, Addison Road, to West London Extension Joint Railway, West Brompton, to S.E. & C. Railway, Loughborough Junction, and Snow Hill.

NOTE.—Trains coming from High Wycombe can only utilise Routes 2 and 3 by way of Greenford and Ealing.

Trains from High Wycombe can also utilise Routes 2 and 3 of G.C. Railway.

LONDON AND SOUTH-WESTERN RAILWAY.

I. Main line from Woking or Guildford and line from Epsom. All trains go through Wimbledon.

II. Line from Staines *via* Feltham.

The branch line from Shepperton can join either route by way of Coombe and Malden or Twickenham.

I. Main line *via* Wimbledon.

Main Route.

Route 1.—To S.E. & C. Railway, Loughborough Junction, and Snow Hill—

(*a*) *Via* Clapham Junction.

(*b*) To L.B. & S.C. and L. & S.W. Joint Railway, Streatham, to L.B. & S.C. Railway, Tulse Hill.

Emergency Routes.

Route 2.—To L.B. & S.C. and L. & S.W. Joint Railway, Streatham, to L.B. & S.C. Railway, Tulse Hill, Peckham Rye, Old Kent Road, to E. London Joint Railway, Deptford Road, and Bishopsgate.

Route 3.—*Via* Clapham Junction, to W. London Extension Joint Railway, West Brompton, to W. London Railway, Addison Road, to Hammersmith and City Joint Railway, Westbourne Park, to G.W. Railway, Bishop's Road, to Metropolitan Railway, Baker Street, and King's Cross.

II. Line from Staines.

Main Route.

Route 1.—To S.E. & C. Railway, Loughborough Junction, and Snow Hill—

(*a*) *Via* Brentford, Kew Bridge, Barnes, and Clapham Junction.

(*b*) *Via* Twickenham, Richmond, and Clapham Junction.

Subsidiary Routes.

Route 2.—To N. London Railway, Camden Town, to Midland Railway, St. Pancras—

(*a*) *Via* Brentford, to N. & S.W. Junction Joint Railway, Kew Bridge, Acton Wells Junction, to L. & N.W. Railway, Willesden Junction, Gospel Oak, and Kentish Town.

(*b*) *Via* Brentford, to N. & S.W. Junction Joint Railway, Kew Bridge, Acton Wells Junction, Willesden Junction to L. & N.W. Railway, Chalk Farm.

Route 3.—*Via* Brentford, Kew Bridge, Grove Road, to Hammersmith and City Joint Railway, Westbourne Park, to G.W. Railway, Bishop's Road, to Metropolitan Railway, Baker Street, and King's Cross.

Emergency Routes.

Route 4.—To N. London Railway, Camden Town, Dalston Junction, and Broad Street—

(*a*) *Via* Brentford, to N. & S.W. Junction Joint Railway, Kew Bridge, Acton Wells Junction, to L. & N.W. Railway Willesden Junction, Gospel Oak, and Kentish Town.

(*b*) *Via* Brentford, to N. & S.W. Junction Joint Railway, Kew Bridge, Acton Wells Junction, Willesden Junction, to L. & N.W. Railway, Chalk Farm.

Route 5.—*Via* Brentford, Kew Bridge, Shepherd's Bush, to W. London Junction Railway, Addison Road, to West London Extension Junction Railway, West Brompton, to S.E. & C. Railway, Loughborough Junction, and Snow Hill.

Route 6.—*Via* Twickenham, Richmond, Clapham Junction, to W. London Extension Joint Railway, West Brompton, to W. London Railway, Addison Road, to Hammersmith and City Joint Railway, Westbourne Park, to G. W. Railway, Bishop's Road, to Metropolitan Railway, Baker Street, and King's Cross.

NOTE.—Routes 2 and 4 can also be followed by way of Richmond.

LONDON, BRIGHTON AND SOUTH COAST RAILWAY.

I. Trains from Redhill which proceed—

(*a*) *Via* Norwood Junction.

or (*b*) *Via* Selhurst.

II. Trains from Epsom and Sutton which proceed—

(*a*) *Via* Mitcham Junction.

(*b*) *Via* Norwood Junction.

(*c*) *Via* Selhurst.

I. Trains from Redhill.

Main Routes.

Route 1.—*Via* Norwood Junction, New Cross, to S.E. & C. Railway, London Bridge, and Snow Hill.

Route 2.—*Via* Tulse Hill, to S.E. & C. Railway, Herne Hill, Loughborough Junction, Snow Hill—

(*a*) *Via* Norwood Junction and Crystal Palace.

(*b*) *Via* Selhurst and Streatham.

Emergency Routes.

Route 3.—*Via* Norwood Junction, New Cross, to E. London Railway, Deptford Road, and Bishopsgate.

Route 4.—*Via* Tulse Hill, Peckham Rye, Old Kent Road, to E. London Railway, Deptford Road and Bishopsgate—

(*a*) *Via* Norwood Junction and Crystal Palace.

(*b*) *Via* Selhurst and Streatham.

II. Trains from Epsom and Sutton.

Main Routes.

Route 1.—*Via* Norwood Junction, New Cross, to S.E. & C. Railway, London Bridge, and Snow Hill.

Route 2.—*Via* Tulse Hill, to S.E. & C. Railway, Herne Hill, Loughborough Junction, and Snow Hill—

(*a*) *Via* Mitcham Junction and Streatham.

(*b*) *Via* Norwood Junction and Crystal Palace.

(*c*) *Via* Selhurst and Streatham.

Subsidiary Route.

Route 3.—*Via* Clapham Junction, to S.E. & C. Railway, Loughborough Junction, and Snow Hill—

(*a*) *Via* Mitcham Junction and Wimbledon.

(*b*) *Via* Mitcham Junction and Streatham.

Emergency Routes.

Route 4.—*Via* Norwood Junction, New Cross, to S.E. & C. Railway, London Bridge and Snow Hill.

Route 5.—*Via* Tulse Hill, Peckham Rye, Old Kent Road, to E. London Railway, Deptford Road, and Bishopsgate—

(*a*) *Via* Mitcham Junction and Streatham.

(*b*) *Via* Norwood Junction and Crystal Palace.

(*c*) *Via* Selhurst and Streatham.

NOTE.—The line from Oxted, run conjointly with the S.E. & C. Railway, can employ any of the routes from Redhill, and also routes over the S.E. & C. Railway, for which see thereunder.

SOUTH-EASTERN AND CHATHAM RAILWAY.

I. Routes *via* New Cross.

II. Routes *via* Bromley.

I. Routes *via* New Cross.

Main Route.

Route 1.—*Via* New Cross, London Bridge, and Snow Hill.

Emergency Route.

Route 2.—*Via* New Cross, to E. London Joint Railway, Deptford Road, and Bishopsgate.

NOTE.—The various lines from Chatham which can employ either of these routes are—

1. *Via* Chislehurst.
2. *Via* Hither Green.
3. *Via* Charlton Junction, Blackheath, and Lewisham.

The line from Dartford proceeds *via* Lewisham.

II. Routes *via* Bromley.

Main Route.

Route 1.—*Via* Loughborough Junction and Snow Hill—

(*a*) *Via* Bromley, Beckenham, and Herne Hill.

(*b*) *Via* Bromley, Beckenham, to L.B. & S.C. Railway, Crystal Palace, Tulse Hill, to S.E. & C. Railway, Herne Hill.

(*c*) *Via* Bromley, Nunhead, to L.B. & S.C. Railway, Peckham Rye, to S.E. & C. Railway.

Emergency Route.

Route 2.—*Via* Bromley, Beckenham, to L.B. & S.C. Railway, Crystal Palace, Tulse Hill, Peckham Rye, Old Kent Road, to E. London Joint Railway, Deptford Road, and Bishopsgate.

NOTE.—The only line from Chatham which can employ either of these routes is that *via* Chislehurst.

There are also branch lines from Crystal Palace and Greenwich Park which have separate routes. All other branch lines join the main line.

From Crystal Palace and from Greenwich Park.

Route 1.—*Via* Nunhead, to L.B. & S.C. Railway, Peckham Rye, to S.E. & C. Railway, Loughborough Junction, and Snow Hill.

Line from Oxted run conjointly with L.B. & S.C. Railway. For routes over the L.B. & S.C. line see thereunder.

Routes over S.E. & C. Railway—

Main Route.

Route 1.—*Via* Beckenham, New Cross, London Bridge, and Snow Hill.

Emergency Route.

Route 2.—*Via* Beckenham, New Cross, to E. London Joint Railway, Deptford Road, and Bishopsgate.

NOTE.—The above two routes are those employable by trains from Addiscombe Road and from Hayes.

GREAT EASTERN RAILWAY.

I. Main line from Cambridge.

All trains run through Tottenham.

Main Routes.

Route 1.—*Via* Bethnal Green and Bishopsgate—
- (*a*) *Via* Clapton Junction and Hackney Downs.
- (*b*) *Via* Loughton Junction and Stratford.
- (*c*) *Via* Loughton Junction and Channelsea Junction.

Route 2.—*Via* Stepney and Goodman's Yard—
- (*a*) *Via* Loughton Juncton and Stratford.
- (*b*) *Via* Loughton Junction and Channelsea Junction.

Subsidiary Routes.

Route 3.—*Via* Loughton Junction, Victoria Park, to N. London Railway, Dalston Junction, and Broad Street.

Route 4.—To Tottenham and Hampstead Junction Joint Railway, South Tottenham, Highgate Road, to Midland Railway, Kentish Town and St. Pancras.

II. Line from Chingford.

All the above routes are available.

III. Line from Ongar.

Routes 1–3 above are available by way of Loughton Junction.

IV.—Lines from Enfield and Cheshunt.

(1) All trains can proceed *via* Angel Road and Tottenham, and thus employ any of the routes above.

(2) All trains can proceed *via* Seven Sisters.

Main Routes.

Route 1.—*Via* Bethnal Green and Bishopsgate—
- (*a*) *Via* Seven Sisters and Hackney Downs.
- (*b*) *Via* Seven Sisters, Clapton Junction, and Hackney Downs.
- (*c*) *Via* Seven Sisters, Loughton Junction, and Stratford.
- (*d*) *Via* Seven Sisters, Loughton Junction, and Channelsea Junction.

Route 2.—*Via* Stepney and Goodman's Yard.
- (*a*) *Via* Seven Sisters, Loughton Junction, and Stratford.
- (*b*) *Via* Seven Sisters, Loughton Junction, and Channelsea Junction.

Subsidiary Route.

Route 3.—*Via* Seven Sisters, Loughton Junction Victoria Park, to N. London Railway, Dalston Junction, and Broad Street.

V. Line from Wood Green.

All trains can employ any of the above routes except Route 4 above.

VI. Line from Colchester.

All trains run through Stratford.

Main Routes.

Route 1.—*Via* Stratford, Bethnal Green, and Bishopsgate.

Route 2.—*Via* Stratford, Stepney, and Goodman's Yard.

Subsidiary Route.

Route 3.—*Via* Stratford, Victoria Park, to N. London Railway, Dalston Junction, and Broad Street.

VII. Line from Beckton, North Woolwich, and Gallions (Port of London Authority).

Main Routes.

Route 1.—*Via* Stratford Market, Bethnal Green, and Bishopsgate.

Route 2.—*Via* Stepney and Goodman's Yard—
- (*a*) *Via* Stratford Market.
- (*b*) *Via* London, Tilbury, and Southend Railway, Bromley, to G.E. Railway.

Subsidiary Route.

Route 3.—To N. London Railway, Dalston Junction, and Broad Street—
- (*a*) *Via* Stratford and Victoria Park.
- (*b*) To London, Tilbury, and Southend Railway, Bromley.

VIII. Line from North Greenwich and Blackwall.

Main Route.

Route 1.—*Via* Stepney and Goodman's Yard.

Subsidiary Route.

Route 2.—*Via* Burdett Road, to N. London Railway, Dalston Junction, and Broad Street.

London, Tilbury and Southend Railway.

All lines run to Barking.

Main Routes.

Route 1.—*Via* East Ham, Bromley, to G.E. Railway. Stepney, and Goodman's Yard.

Route 2.—*Via* Forest Gate, to G.E. Railway, Stratford, and Bishopsgate.

Subsidiary Routes.

Route 3.—*Via* East Ham, Bromley, to N. London Railway, Dalston Junction, and Broad Street.

Route 4.—*Via* Forest Gate, to G.E. Railway, Stratford, Victoria Park, to N. London Railway, Dalston Junction, and Broad Street.

Emergency Route.

Route 5.—*Via* Forest Gate, to Tottenham and Forest Gate Joint Railway, South Tottenham, to Tottenham and Hampstead Junction Joint Railway, Highgate Road, to Midland Railway, Kentish Town, and St. Pancras.

North London Railway.

From Poplar.

Main Route.

Route 1.—*Via* Dalston Junction to Broad Street.

APPENDIX B.

A List of London Goods Stations.

* "Selected carriers" include all railway companies' vans and all those of the following public carriers, viz., The Atlas Express Company, Messrs. Chaplin & Co., the Globe Parcel Express, Messrs. Sutton & Co., Messrs. Thompson, McKay & Co., the London Parcels Delivery Company, Messrs. Carter, Paterson & Co., and Messrs. Pickford & Co.

† These figures relate to Aldgate at junction of Fenchurch Street and Leadenhall Street.

APPENDIX D.

Extract from the Report of the "Railway Times" on Sir Alexander's Henderson Speech at the Half-yearly Meeting of the Great Central Railway, held on February 11th, 1903.

Speaking of railway difficulties Sir Alexander Henderson said :—

"Some of those difficulties were of their own making, and the keen competition—he might almost say the scramble for every ounce of traffic—was to be regretted, but it was hardly likely to be altered until the companies put all their horses together.

"That such a combination would result in great benefits to railway shareholders and to the public, he had not the slightest doubt.

"The economies that could be effected by such a combination were enormous. Taking only the six companies carrying between Manchester and London, the total of their expenditure on collection and delivery of merchandise alone must

come to something like £2,500,000 per annum, and it would no doubt be possible, if some pooling arrangement were entered into, to save a considerable part of that heavy item. That only represented one direction in which economies might be effected. It might be urged that a combination of the railways might be to the disadvantage of the traders and the public, but he was convinced that the interests of the public and the traders could be amply protected and that benefits would accrue from it to the public to an extent quite equal to those that would be received by railway proprietors."

DISCUSSION.

The Chairman, in opening the discussion, said the applause with which the paper had been received intimated how much it had been appreciated. When one's attention had been called to the subject, one realised how the traffic was very much blocked by a large number of goods vans—in nearly all cases empty — getting into each other's way, and stopping outside warehouses. The same thing could be noticed in travelling on a railway. When a large town was being approached a wilderness of shunting yards was passed through, where trucks were, as Mr. Gattie so picturesquely put it, being banged about in a complicated way. It would be realised that the railway companies had to face a very difficult problem when they tried to do shunting and sorting on one plane, that was to say, in one dimension and with only an endways movement. That was obviously a very bad system. Mr. Gattie had referred to the human race as being "creatures of habit." He thought Mr. Gattie might have used a stronger term and said "savages." People had the savage instinct very strongly, especially in a civilised country, and when anything new was proposed in the way of improvement that savage instinct was seen to its best advantage. A person did not, of course, oppose his own new thing, but he opposed everybody else's. Mr. Gattie very boldly faced the big end of the subject, and he was quite right in so doing. By beginning at the big end he had shown how big the problem he was tackling really was. One difficulty which had at the present time to be faced in London was the making of new streets for the accommodation of the traffic, but if Mr. Gattie was right, his scheme would obviate that difficulty, thereby saving an enormous amount of money, probably enough to provide for the proposed new Clearing House.

Mr. H. E. Roper said the author had given an instance of a truck going from Bristol to Brighton, and when it got to Old Oak having to be taken off the Great Western train, put into a siding, then taken by a Great Western engine to another yard, where it was again marshalled into a siding till the Brighton train started. He assumed the whole of the goods in that wagon were for the one destination, namely, Brighton, so he did not quite follow what the object was in taking them out of one truck and putting them into another.

Mr. C. Urquhart Fisher said Mr. Gattie seemed to have been born before his proper time. He thought a great drawback of the present system of locomotion in London was the enormous number of vans in the streets. The public, as a whole, had to be considered, and he did not agree with any railway manager who said that there had been a great improvement with regard to railway companies' vans during the last five years. At the present time such vans, some of them as big as pantechnicons, and always a great many of them empty, caused a serious blockage in the streets. The London Chamber of Commerce had appointed a committee to look into the details of Mr. Gattie's scheme, and he might go further and say that many gentlemen, who had scientific knowledge, on the County Council had endorsed the scheme. He was sure, when it came forward in full detail, it would be greatly appreciated and better understood by the public at large.

Mr. Lewis R. S. Tomalin thought it was a most striking fact that no one had attempted to refute or to amend the figures and facts which Mr. Gattie had brought forward, which surely would have been the case if Mr. Gattie was bringing forward an impossible or mad scheme, and misleading the public. All Mr. Gattie's statements were founded on the results of an enormous amount of research and industry, and he could be trusted. He (the speaker) could remember the state of the traffic in the City for the past forty-seven years, and he maintained that the obstruction of the streets was worse at the present time than it ever was before. Mr. Gattie had not made it quite clear that evening that the collecting carts of the proposed Clearing House would be motor-wagons. Those motor-wagons would take the containers with goods to a warehouse, say, in Wood-street, the containers would be promptly hoisted off, other containers with goods going from Wood-street to the Clearing House would be substituted, and off they would go, the result being there would be very little delay or waiting of the lorries outside the warehouse, and, of course, the transit through the streets would be much more rapid. From every point of view, as a commercial man who believed, without having any scientific or expert knowledge, that he thoroughly understood the wants of London in that respect, he strongly endorsed Mr. Gattie's scheme, and trusted that the fact of his having been permitted to read his paper before such a very old and highly-thought-of society as the Royal Society of Arts, would aid him in obtaining more publicity and more support.

Mr. S. Chapman referred to the fact that most of the goods traffic arrived in London in the early morning by the means of 290 trains according to Mr. Gattie. With the most improved appliances those

290 trains could be promptly unloaded in the Clearing House, but it had occurred to him (the speaker) that at the precise moment when those trains were unloaded there would not be the corresponding amount of goods with which to reload them, and, therefore, they would be standing idle until the evening traffic came along. He also appreciated the system of contacts and the method of conveying the parcels from one section of the flooring to another, but he would like to ask one question with regard to documentation. One got as far as the documentation of the container when it had reached the floor, but if the container was to be disposed of with the greatest rapidity, how was the documentation going to be carried on from the point when the goods were unloaded from the container and distributed to various other parts of the premises? If the documentation was to be made out for each separate package at the precise moment, the time occupied in bringing it would not be quite so short as might be assumed from the author's remarks. Another point was that assuming that 2,000 wagons did the work of 10,000, and they took a shorter time owing to the facilities offered by the Clearing House, it might readily happen that a large proportion of those wagons would make two or more journeys through the streets, and if so, although the actual number was only 2,000, there would be as much congestion as if there were 5,000 or 6,000 wagons in the streets.

Mr. HENRY MURRAY said the erection of such a Clearing House would cost a large amount of money, and he inquired if the author distinctly saw his way to showing any considerable profit on the cost of that erection. Could he give any figures indicating what that profit might be reckoned at on the basis of current rates?

Mr. C. E. RATCLIFFE inquired if there would be any provision in the nature of private sidings or warehouse accommodation. Also, would any provision be made for the public to do their own carting? Many consignees had premises close to certain stations, which premises would be a long way from the Clearing House, and this would be a disadvantage to those people. Was it intended that in addition to the traffic being bulked in the Clearing House for subsequent distributions, such matters as accounts, correspondence and claims would also be dealt with there? Carrying that further, suppose one vanload contained consignments from half a dozen railway companies, how would the money be collected and redistributed to the different companies?

Mr. M. H. MATTHEWS asked if Mr. Gattie had made any special arrangements for handling goods of a special nature. It had been mentioned that the containers were 11 feet in length, which he, the speaker, supposed would be for normal traffic. He therefore presumed that bridge girders, for instance, would have to be handled at special times of the day, as at present.

Mr. W. L. MADGEN remarked that anyone having any knowledge of electrical engineering and the possibilities of endowing apparatus with selecting faculties by means of electricity, would see that sooner or later a device of the kind under discussion was inevitable. He himself did not see any serious practical difficulty in carrying Mr. Gattie's scheme into effect. He might mention one matter in which he thought the author would probably be disappointed. Mr. Gattie appeared to believe that his system of dealing with the goods traffic of the Metropolis would alleviate the congestion of the streets. He (the speaker) did not think it would. It was promised, with the introduction of tubes and every other movement in the direction of facilitating passenger and other traffic, that that congestion would disappear, but, as a matter of fact, it was worse at the present time than ever it had been. He thought there was only one solution of that, namely, an organised redistribution of industries, and one of the greatest obstacles to that was the attitude of the governing bodies of the Metropolis, including the County Council, which, they had heard that night with considerable surprise, contained some scientific men.

Mr. S. WATERS believed, as a railway man, it was possible for railway companies to remodel their system so as to make a greater use of electricity. He was glad to see that Mr. Gattie had provided for a greater use of electrical apparatus in his scheme, but the chief difficulty which he (the speaker) could see in the scheme would account also for the opposition of the railway companies themselves. Mr. Gattie's scheme would take away a very large part of the railway companies' revenue derived from the delivery of goods, and how did he propose to compensate the railway companies in that respect? Mr. Gattie proposed to have tubes running from the London goods termini into the Railway Clearing House, and proposed to transfer the goods from the railway trucks into certain receptacles which would be placed in special trays and run through the tubes into the Clearing House. He would like to inquire how that was going to be done, and at whose cost, and also who was going to do the checking which would be necessary to ensure the safe transit of the large number of articles which would go through the tubes day by day? If the Clearing House proposed to do it, it would necessitate having a large staff at the railway station. Another point was how was it proposed to determine the route that the goods should travel, and who would determine which company was to be favoured with the traffic?

Mr. GUY LIDDELL referred to the value of co-operation in the establishment of a Goods Clearing House and in that connection quoted the case of the Port of London Authority and the great appreciation in the shares of those railway companies who had some time ago entered into a working agreement. The Committee of the Board of Trade on Railway Agreements, in its

report, had also given a most favourable verdict on the principle of co-operation among railway companies in this country. Mr. Gattie had made out a good case for the adoption of his scheme. There was such an enormous amount of overlapping in regard to the collection and delivery of goods in London that a more uneconomical or unsystematic scheme could not well be imagined. The streets of London were crowded with vans competing for vulgar fractions of goods, and their presence greatly impeded the time-saving traffic. Every class of person desired a change, and he appealed for the hearty co-operation of the railway companies to carry Mr. Gattie's scheme forward.

Mr. A. G. SEAMAN said the author had called attention to the large proportion which the cost of carriage formed of the cost of articles. This country at present possessed the great economical advantage that its manufacturers were more or less concentrated within limited areas. That was not the case in America, where the more important manufacturing centres were in many cases hundreds of miles apart. Directly it was admitted, as it had to be, that the principal cost in transferring goods was not the cost of forwarding them from one place to another, but was the cost of handling the goods at the terminals, it would be found that this country was wasting a very great economic advantage which it at present possessed by its manufacturers being close together.

Mr. E. EVANS said the author had mentioned that a goods truck's life was seventeen years, and that it was only mobile on the track for six months during that time, but he (the speaker) took it that Mr. Gattie included coal trucks, which were allowed to remain at the docks waiting for shipment for a considerable time. Miles and miles of them could be seen in Wales, and it was hardly fair to take such trucks into account. With regard to the style of wagon, he took it that the containers would have to be loaded up by the cranes when the goods were loaded in close-roofed vans. That would take a considerable time for the loading-up of the containers for distribution to the different parts of the Clearing House. It seemed to him that decentralisation would relieve the congestion of the streets of London, and that was what the railway companies had done by putting depôts convenient to the places of business of their customers. If a system of concentration was adopted the congestion of the streets would be increased. Then there were receiving offices all over London. It was hardly likely they would be done away with. The only way was to adopt some system of steam, electric or motor traction for conveyance of goods, and so speed the traffic along; but that system could be adopted, and he believed was being adopted by the railway companies.

Mr. GATTIE, in reply to Mr. Evans, said that his estimate of the life of a railway goods truck and its mobility on the track was arrived at from a calculation on the whole of the goods and mineral trucks, and his answer to the question was in the affirmative. If Mr. Evans would read the copy of the London Chamber of Commerce proceedings he would see that the whole of the trucks were taken in arriving at the calculation, which showed a 3 per cent. efficiency. He had also, with very great difficulty, worked out the efficiency for the general-merchandise truck, and found it was as nearly as possible the same. With regard to the question of decentralisation, he thought he had shown that there would be 2,000 wagons on the streets instead of about 30,000 or 40,000, and the question was, which would occupy the more space? His 2,000 cars would make about four journeys, but that showed they would not be standing still. What caused congestion in the streets was not the moving but the stationary traffic. The question must be reduced to van-space minutes. If a car which went two miles an hour through the streets was taken, it would occupy the streets for the journey done exactly twice as long as a car going four miles an hour. Turning again to Mr. Evans's remarks, he would point out that the distance from the centre to any point on the circumference was the same. The car miles of the Clearing-House system, although it did not appear so at the present time, were really less than when a great number of journeys had to be made. Those were only determined by most careful calculations, diagrams and curves, which he had not had time that evening to produce. He could simply assert that it was so. With regard to the division of the moneys and the taking away of the profits made by the railway companies at the terminals, supposing there was a business which cost the railway companies 1*s*. and which cost the New Transport Company 3*d*. to do, it was clear to his mind that the railway companies might have one-third, the public might have one-third, and the New Transport Company might have one-third, and nobody would be injured. With regard to the question of the difficulties which took place in booking, the best way was to make it all through traffic. There was no difficulty in booking through between the London, Brighton Company and the South-Western Company and why should there be any more difficulty in booking things either to or from the New Transport Company? Even if the New Transport Company was regarded as a carrier company, the same thing happened every day with the eight hundred other carrier firms in London. To Mr. Chapman's question, the best answer he could give was to ask what was the documentation of the hand-truck system. He was substituting for the hand-truck an electrical apparatus which he firmly and honestly believed would do the work of eighty men, but there was no alteration involved in documentation. The belt sections he had referred to must be regarded as human machines, only they were much more efficient; they could do more work, carry heavier

loads, and did not get tired. Whatever applied to the present system of documentation and the hand-truck, equally applied to the electric system. There was also the further point that the electric carrier was absolutely honest, and therefore he thought the book-keeping need not be quite so strict as under the present system. One speaker had inquired how goods exceeding 11 feet in length would be dealt with. Such goods would not be placed in containers, because they could not be; but the Clearing House was a fairly large place, and there would not be the slightest difficulty in lifting a girder even of 60 feet length. With regard to what one gentleman had said about how traders living near to goods stations would be affected, it was very nice perhaps for a man who owned a horse and cart to be next to Bricklayers' Arms Station, for instance. It would be very easy for such a man to go into that station. But how long would his horse and cart remain there? (A voice: "For hours.") He quite agreed, and that appeared to him to be a very costly thing. According to the New Transport Company's system, one of their cars would call for the man's goods—he would not be bothered about the matter at all—and therefore that horse and cart would not be wanted. Another question asked was, Would there be any storage accommodation in the Clearing House? The answer was in the affirmative. There were 117,000,000 cubic feet of space, and that represented a large space. With regard to possible profits, that question had been gone into very carefully by chartered accountants (who, of course, could not certify anything but facts), and it had been found that taking current rates, on a revenue of £10,000,000, something over £6,000,000 a year would be saved. That was a 60 per cent. proposition. Then an important question had been asked, How could the trains be reloaded up when there were not the available goods with which to do that? His company had approached every railway company and asked for details and information. When the railway companies gave that information he guaranteed that within one calendar month the Clearing House time-table would appear which would show the time of arrival and departure of every train, what it was being loaded with and its destination. The difficulties were caused by the railway companies themselves. The New Transport Company did not intend necessarily to adhere to the exact time-tables of the railways, because those were made so as to fit in with the present arrangements. With new arrangements new time-tables would be adopted. The new Clearing House would receive a train, unload it, reload it with goods which had accumulated in the Clearing House, and send it away again, and, astonishing as it might seem, a goods train with fifty trucks could easily be unloaded and reloaded in ten minutes.

On the motion of the CHAIRMAN, a vote of thanks was accorded to Mr. Gattie, and the meeting terminated.

THE PRODUCTION OF MOCHA COFFEE.

All the Mocha coffee grown in the world comes from the Yemen, a Turkish province in the south-western part of Arabia, and is so called because the entire crop was formerly shipped from Mocha. The trade is now wholly divided between Hodeida and Aden, the bulk of it going from the latter port. Coffee can be grown successfully, probably, in any of the mountainous parts of the Yemen, but its cultivation is, in fact, confined to a few widely-scattered districts and the acreage is relatively small. This is due to the fact that the Yemen Arab never uses coffee himself, contrary to general opinion and the reports of some travellers, but cultivates it almost entirely for export. He uses "Kishar," a beverage he brews from the dried hulls in large quantities, but it is certain that he never would devote much land or labour to the cultivation of the berry for its hulls, because there would be little profit in it. In cultivating coffee for export, the Arab realises a good profit in money when his trees yield their crop and it is sold. But he must wait four years after planting, during which the cost of labour is heavy, before his trees begin to yield, and the main desideratum with him is not money but food. In a land where the barter of commodities is difficult, through lack of means of communication, money may mean clothing and comforts, but the one necessity is food, and he may not always be where he can buy food with his money. In consequence the Yemen Arab devotes little of his land to coffee, and very much excellent coffee land to dhurra, a plant resembling Indian corn in appearance but producing a grain like millet. He argues that, however superior the money-getting qualities of land planted with coffee, he gets sixteen crops of dhurra while waiting for one of coffee, and is sure that his family is safe from starvation. According to the American Consul at Aden, the principal coffee regions are in the mountains between Taiz and Ibb, and between Ibb and Yerim, and Yerim and Sanaa on the caravan route from Taiz to Zabeed; between Hayelah and Menakha on the route from Hodeida to Sanaa, and in the wild mountain ranges both to the north and south of that route; between Beit-el-Fakih and Obal, and between Manakha and Mathan to the north of Bajil. Of all Yemen or Mocha coffee the best is that known as Mohtari, from the district of Beni Mohtar lying almost due south of Sanaa. Another nearly, if not quite as good, comes from Yafi, near Taiz. Other kinds that are considered superior are Sharsh, Menakha, and Hifash. It is said that all these coffees are the same variety, and that the superior quality of any of the so-called kinds is due wholly to the curing. In Beni Mohtar the coffee lands are held by large and wealthy proprietors, whose means enable them to hold their crop for some months after it is gathered. The berries picked in September are accordingly stored away, and allowed to cure all the winter. The bean thus dries out thoroughly before it is hulled and brought to market. This accounts for the clear,

almost translucent yellow colour of the finest berries when they reach the market. The planters in the other districts, however, are compelled to sell their crop quickly in order to tide over the winter. Hence they pick the fruit before it is properly ripened and hull the berry before it is properly dried. As a result, the colour is pale and lifeless, the flavour weak and flat compared with the berry cured within the hull. So little is coffee used by the people, that a few months after the new crop has been gathered it is impossible for one passing through the country to buy a single pound except at Hodeida and Sanaa.

BRONZE CASTING IN SIAM.

According to old records, the art of bronze casting was introduced into Siam by the Chinese in the eleventh century. Bronze, however, has been known throughout Indo-China since the earliest times, as shown by the discoveries of bronze hatchets and arrow-heads in limestone caves and other places of deposit of pre-historic remains. Ancient bronze figures of Indian divinities and of the Buddha testify to the early employment of the bronze founders in these cults in Siam. Figures of the Buddha are found in the north of Siam in great numbers on the sites of ancient temples which have been crumbling for centuries, leaving the majestic bronze figures standing enclosed by great forest trees. The interesting point about these figures is the perfect condition of the bronze after centuries of exposure to a tropical sun and rains. This bronze is called by the natives "samrit"—the perfect or auspicious alloy—and its composition for a long time remained a secret, until, according to the American Consul at Bangkok, a few years ago the formula was discovered in an old Siamese manuscript belonging to the late King of Siam, of which the following is a translation:—"Take twelve ticals (one tical is equal to one half-ounce avoirdupois) weight of pure tin, melt it at a slow fire, avoiding bringing it to red heat. Pour two ticals weight of quicksilver, stir until the latter has become thoroughly absorbed and amalgamated, then cast the mixture in a mould, forming it into a bar. Take one catty in weight (eighty ticals) of refined copper and melt it. Then gradually incorporate with it the amalgam, keeping in the meantime the fused mass well stirred. When this has been done, throw into the crucible a sufficient quantity of ashes obtained from the stems of the 'bua-bok' (lotus) creeper, so as to cover the molten metal. Remove the dross with an iron ladle; the metal remaining is samrit bronze." According to this recipe, the proportion of the ingredients employed in the manufacture of the alloy in question thus proves to be 85·11 copper, 12·76 tin, and 2·13 quicksilver. One of the best known statues of the Buddha cast of samrit bronze may be seen in the city of Pitsanuloke, Siam. This figure dates from the beginning of the eleventh century, and ranks among the most beautiful objects of art that the Siamese have ever produced. Samrit bronze was also much used in old days for casting vessels and implements for sacred uses, and was supposed to be endowed with mystic qualities. The art of casting bronze Buddhas still forms quite a home industry. The method followed is to mould a figure in clay and coat it with wax, and then apply a coating of clay; the wax is melted by the application of heat and the molten metal poured in. When cold, the mould is broken, and the figure cleaned and polished. In the temples of Bangkok may be seen many fine specimens of modern statues of the Buddha, which compare favourably with those of other countries.

HOME INDUSTRIES.

The Sale of Milk.—The Acreage and Live-Stock Returns for 1910 just published, show that for the first time since 1902 the number of cows and heifers in milk or in calf have decreased, the total for 1910 being 26,500 less than in the previous year. In the North Riding of Yorkshire alone there has been a decrease of 1,235 cows and heifers as compared with 1909, and in the county of Durham a decrease of 876. It is to be noted that the decrease in 1910 as compared with 1909 is to be found in Wales and Scotland as well as England, but it is principally in England and in the north-eastern and northern districts that this decline is shown for the first time during the thirty-five years covered by these tables. Mr. Rew says that the causes of this loss are not very apparent, but it may be assumed to have been mainly due to temporary or accidental causes. It is at least remarkable that, notwithstanding the ever-increasing demand for milk by a rapidly growing population, the stock of cows is actually decreasing in Great Britain, and in the north of England decreasing in a somewhat marked degree. The explanation of this untoward change may well be found in the administration of the Sale of Milk Regulations, 1901. Milk is liable to fall below the presumptive limits fixed by the Milk Regulations, which is almost always the 3 per cent. of butter-fat. Now many farmers have been brought up in the police-courts, and magistrates have treated the presumptive standard of the regulations as being virtually an absolute standard. But the liability of the milk to fall below the presumptive 3 per cent. of butter-fat was well known before the regulations were drawn up, and was admitted by the Departmental Committee which sat in 1900. It was less generally known until recently that the dairy herds in the north of England are specially liable to give milk below the standard at frequent but irregular intervals, and from no ascertainable cause. The fact has been proved to demonstration by the publication of the results of experiments carried out on behalf of the Durham County Council at the Offerton Dairy Farm in the early part of 1909. The mixed milk of a herd of five specially-selected dairy cows was subjected to daily

analysis. The cows were liberally fed, and yet it was found that in eighty-four separate tests the morning's milk fell below the 3 per cent. standard eighty times, the weekly average of the butter-fat falling on several occasions to 2·5. Similar results followed experiments made on behalf of the North and West Riding County Councils at Garforth Experimental Farm, and much other evidence has accumulated, all tending to prove that the liability to variation in the quality of milk, particularly in the spring, is so frequent and so general that no milk-producer can hope to escape trouble with the local authorities if the sampling officers are zealous in the discharge of their duties. And they seem to be very zealous in the north, where they are encouraged by magisterial decisions that have over-much regard to the strict letter of the law. The result is widespread agitation among the farmers, who at a representative meeting at Stockton-on-Tees last week demanded the immediate suspension of the Sale of Milk Regulations, pending a full inquiry into the administration of the Sale of Food and Drugs Acts as they affect the dairying industry in the north of England. It may be hoped that the Government will see their way to accede to a request that would appear to be necessary to the well-being of a very important industry.

The Coal Mines Bill.—The Miners' Federation have drafted a clause to the Coal Mines Bill respecting the inspection of mines which, if accepted by Parliament, will compel the employment at every mine of an inspector who will be solely occupied with examining and reporting upon the safety of the mine. This inspector will have nothing to do with the production of coal. He will be engaged by the men, subject to the approval of the mine inspector, and will not be liable to dismissal except with the consent of the district inspector appointed by the men. Duplicates of his reports will have to be sent to the mine inspector every fortnight. The qualifications of these inspectors are to be fifteen years' experience in a coal-mine, five of which have been spent at the coal face, and their appointment is to be by ballot of the miners. Moreover, if the miners show by a majority that they have lost confidence in the inspector, they will have the right to compel him to submit himself to a ballot for confirmation or rejection.

Sulphate of Ammonia.—The output from coke ovens may be expected to be largely increased as a result of orders placed for batteries of ovens during recent months. They are not likely to affect the output for the current year, but must have considerable effect upon that of 1912. Sulphate of ammonia is becoming increasingly popular, and the demand is expected to be quite equal to the increased supply. To the Scotch mineral-oil trade sulphate of ammonia is a by-product of great value, and it is expected that the forthcoming reports will show that it has been a main source of profit. The price of sulphate of ammonia has risen very considerably in recent months. Recently it was over £14 per ton, and although now lower there is, at present prices, a big margin of profit, since the cost of production is not more than £5 per ton. Great Britain and Germany are the principal producers, Germany producing last year 373,000 tons against Great Britain's 369,000 tons. The United States produced 116,000 tons, France 56,000 tons, Belgium and Holland 43,000 tons, and the rest of the world 100,000 tons. Of the British production, 168,000 tons are produced at gas-works, 120,000 tons at coke and galvanising works, and from producer gas, 60,000 tons from shale, and 21,000 tons from blast furnaces. The British exports last year amounted to 248,000 tons, and the home consumption to 87,000 tons.

The Motor Liner.—There would seem to be no foundation for a report that has been current to the effect that the Hamburg-American Company has decided to abandon its experiment in the construction of a motor liner. On the contrary, the Company is understood to have just placed a contract for a similar vessel with a Bremen firm, and has the intention to order an even larger boat than the two of 6,500 tons each now on order. It is said that other German companies, including the Hamburg-South American Company, also have ocean-going motor-boats in course of construction, whilst the Danish East Asiatic Company is building two for its New York service, one on the Clyde and another at Copenhagen. A Tyne-built oil-engined vessel, the "Toiler," will be the first of the kind to cross the Atlantic, but it must be admitted that the pioneer work has been mostly done by foreign companies. It looks, however, as if there will be more activity in home ports in this connection before long. A motor cargo-boat of considerable size is being built for Lord Furness, and an order was recently given for an oil-tanker of 6,000 tons, which is to be fitted with Diesel engines.

Trawling and the Three Mile Limit.—Considerable sympathy must be felt with those who are endeavouring to induce the Government to extend the three mile limit within which fishing by means of beam or "otter" trawl is at present prohibited. In recent years the position has been completely changed by the steam trawlers, now so common. Their methods are terribly wasteful and destructive, not only of fish, but of fish-spawn, and in many districts the line fishermen, who in Scotland number some 13,000 men and boys, find their occupation almost gone. The representatives of the line fishermen are urging the Government to recover freedom of action for this country, which is at present bound by the North Sea Convention, and by international agreement, to fix a general twelve mile limit against steam trawlers. It will be remembered that Russia has recently put in force a twelve mile limit in the White Sea, a proceeding against which the British Foreign Office has protested. But having regard to the havoc

wrought by the steam trawler, there would seem to be a good deal to be said for imitating Russian procedure in this respect. It cannot be to the national advantage to see the line fishermen disappear, and this is what must happen if they are not to be more fully protected against the depredations of the trawler.

Ireland's Canals.—The final report of the Royal Commission on the canals and inland navigation of Ireland has now been issued. It recommends the creation of a controlling authority for the purpose of taking over those inland waterways which are already under the control of the State, of local authorities, or of a public trust, and of acquiring such other waterways as are determined to be of importance. This controlling authority, the Commissioners consider, should be entitled the Water Board, should form a branch of the Department of Agriculture for Ireland, and should consist of three or five Commissioners, one of whom should be paid and give his whole time to the work. Lord Farrer does not sign the report, because in his opinion there ought to be no further administrative changes in Ireland involving a charge on the public purse unless and until a purely Irish elected authority has agreed to pay for them. Lord Farrer is alarmed at the growth of public expenditure in Ireland, which, in his opinion, will not be checked unless the people who benefit have themselves to pay for public improvements. The commodities carried by Irish canals consist mainly of coals, bricks, timber, sand, turf, oats, flour and grain, and such agricultural requisites as artificial manures, grass seeds, etc., besides a fair proportion of general cargo. They are, therefore, calculated materially to benefit the farmer if their efficiency is maintained.

The Manning of British Ships.—Considerable discussion has arisen upon a letter addressed by Messrs. Glen & Co. to an official of the Seamen's Union who had protested against the practice of the Company in employing Chinese as firemen in their steamers. Messrs. Glen & Co. say that this preference is not due to motives of economy. The wages are practically the same as with Europeans. But Messrs. Glen & Co. go on to say that they "would be quite prepared to pay considerably higher wages to Chinese than we would to Britishers, as they are much more sober and steady, and do their work much more efficiently." That is not a statement that can be supported by adequate evidence. It may be more or less true, as Mr. Cuthbert Laws, the General Manager of the Shipping Federation, says, of the tramp steamship that goes anywhere, with no fixed route; but is certainly not true of vessels trading regularly from port to port—the home coasting trade and liners both in the foreign and home trade. In certain Eastern trading vessels that are away from home for irregular periods the Chinese, for many purposes, are preferred. They are better adapted to the climate, and do not get restive, want to get home, and finally desert their ships, as the British sailor does. But it is not well to generalise too much. Chinese and other foreign seamen are preferred by many skippers because they do not resent ill-treatment, physical ill-treatment, as the British sailor does. It is, oftener than not, the skipper rather than the owner who prefers the Chinaman or Lascar.

The Motor-Cab Industry.—It is too soon to speak with any certainty as to the prospects of the motor-cab industry and its attractions (if any) for the investor. It is obvious that the industry has great and exceptional difficulties to face. The operating companies are pioneers. The industry is only about six years old. In 1905 there were only nineteen motor-cabs in service in London, in March, 1910, the number had increased to 7,165, and since then there has been a large addition to the number on the streets. But the data are still wanting to enable a decided opinion to be formed as to depreciation and reserve; it is still a matter, more or less, of speculation as to how long rolling-stock will last, and this question goes to the bottom of the business. Nor is the period of the serviceable life of a motor-cab the only one of vital importance with which the existing companies have to reckon. There is a steady improvement in design which threatens to make stock obsolete earlier than it would be from fair wear and tear. And of course competition has to be faced. If the present companies are able to show large profits others will soon be appealing to the public for capital, which will be subscribed under the glamour of large dividends—not that there is much likelihood, so far as can be seen, of such dividends. The oldest and most important of the operating companies, formed five years ago, paid its 7 per cent. preference dividends for the last two years, but the net profit, which for 1908-9 was stated at £225,553, fell in the year ended July 31st, 1910, to £201,525. The second company on the list made a net profit in the financial year ended October, 1910, of £22,064, but the directors did not consider themselves justified in recommending a dividend. A third company has issued accounts for a period of fourteen months to July, 1910, which show a net profit of £5,509, but the other companies have not, as yet, issued any accounts. There is nothing in the available information to modify the opinion expressed in these Notes a year ago that shares in the motor-cab companies must necessarily represent a highly speculative, and therefore, from the prudent point of view, undesirable investment.

NOTES ON BOOKS.

WILLIAM FORD STANLEY. Edited by Richard Inwards. London: Crosby Lockwood & Co. 2*s*. 6*d*. net.

The first five chapters of this slender volume are autobiographical, and give an interesting account

of a remarkable man who rose by sheer ability, persistence and courage, from the smallest beginnings to a position of very considerable influence and wealth. Thanks to the unpractical nature of his father, who, though an excellent mechanic, was cleverer at losing than at making money, young Stanley got no better education than was to be had at a village school—where he learnt spelling, writing and hymns—and a small private school, kept by an ex-bank clerk, who had lost his situation through drunkenness. The lad, however, if he learnt little from his teachers, possessed the art of self-education. Compelled to begin earning his own living at the age of fourteen, he attended classes at the Birkbeck Institution after a ten hours' day of hard manual labour, and, being a diligent student, he soon gained a fair knowledge of English literature, technical drawing, and modelling. After several changes he found himself, at the age of twenty-five, master of one hundred pounds, and he then decided on the step which finally led him to fortune. He took a little shop at 3, Great Turnstile, Lincoln's Inn, and set up there as a maker of drawing instruments. By various improvements which he introduced—notably in the tee-square and the theodolite—Stanley's instruments soon became favourably known to architects and engineers, and he built up the business which has now large factories at Lincoln's Inn, Norwood, London Bridge, and Great Turnstile.

Stanley's autobiography ends about this point, but the rest of the story is told in a few short chapters by the editor, who sketches the character of a very lovable and accomplished man. One of the last acts of his life was the building and endowment of the Stanley Hall and Technical Schools at Norwood, at a cost of some fifty thousand pounds. As he himself said, "he was moved to this enterprise by the painful sense of his own imperfect education, and he was determined that at least some of the rising race should not lack proper teaching." In this institution, Stanley's own views on the ideal technical school are carried out. An hour and a half of book learning or lecture alternates with an hour and a half practical work at the bench, vice or lathe, and by this change of occupation the interest of the students is kept constantly awake.

Mr. Inwards has produced an interesting little volume, which should prove a great encouragement to those who have to make their own way in the world.

The English Staircase. By Walter H. Godfrey. London: B. T. Batsford. 18*s*. net.

In this work Mr. Godfrey gives an historical account of characteristic types of the English staircase, the main body of which belongs to the period 1500 to 1800. As he modestly states, no attempt has been made to write an exhaustive treatise on the subject, but he has been at great pains to collect drawings and photographs of interesting and beautiful specimens, with the result that we have sixty-three full-page plates and over fifty other illustrations. As the work has been published by Mr. Batsford, it is hardly necessary to add that these have been admirably reproduced by the collotype process.

After giving an illustrated outline history of the stone staircase from Norman to Tudor days, Mr. Godfrey describes the new methods of the Early Renaissance, the Jacobean type, and the quiet dignity of the Later Renaissance. The graceful elegance of the Georgian stair, and the application of ironwork to the later design, conclude his review.

Mr. Godfrey in his preface laments that in the general decline of domestic architecture which took place during last century, the staircase reached a lower level than any other feature. It is still far too often cramped into a narrow and badly-lighted well, mainly, no doubt, with the object of curtailing as little space as possible from the rooms; but when one sees how beautiful and striking a feature it may become, one cannot but hope that the architects of the future may be inspired by Mr. Godfrey's book to restore to it some of the splendour of the past.

GENERAL NOTES.

Memorial Tablets. — The London County Council have affixed a memorial tablet to the house known as The Grove, Hampstead, which was from 1856 to 1864 the residence of Sir George Gilbert Scott, architect. The two chief works on which he was engaged at this period were the erection of the Foreign and India Offices in Whitehall, and the preparation for the Albert Memorial. A tablet has also been erected on No. 32, Soho Square, well known as the residence of Sir Joseph Banks, who was for over forty years President of the Royal Society. The house became famous as "a sort of academy of science—the rallying point of science and genius of all countries."

Forestry in Japan.—In a paper entitled "Some Statistics of Japan," recently read before the Royal Statistical Society, Mr. Charles V. Sale gave some interesting particulars relating to Japanese forestry. About 60 per cent. of the area of the country is covered by forests. Of this the State owns 29,186,850 acres; the Crown, 6,152,350 acres; communities and temples own 6,632,150 acres; and private owners, 14,112,000 acres—a total of 55,083,350 acres. "The importance of forestry," writes Mr. Sale, "has been recognised from very early times, and during the Tokugawa *régime* (1603-1867) the most stringent protective rules were enforced. Inasmuch as wood was the only fuel and the only building material, whether for houses or boats, it was necessary that each feudal domain should secure a constant supply of the different timbers within its own borders. Hence arose the practice of regarding the production

of timber in the same light as that of crops, and of enforcing a certain rotation with given periods for cutting and replanting. With the fall of feudal government these restrictions were removed, and for a time there was much reckless felling of timber, especially where it was within easy reach of a market, but in the year 1882 draft forest laws were prepared by officers who had been trained in Germany, and in 1899 the general Forest Law was promulgated. Under this law the State and Crown forests are administered, and the cutting of other forests is regulated. Hitherto, the Forestry Bureau has been principally engaged in laying down the system of management and control. The country is divided into ten districts, with 270 local offices and 1,259 sub-offices. The State forests are all to be managed as a trading concern, small isolated areas are being sold so as to consolidate the estates, and a very considerable amount of replanting is being undertaken—about 100,000,000 trees per annum. The revenue from State forests is expected to increase year by year, and to amount to some millions sterling per annum within two or three decades." The rate of progress during the last ten years has been very striking, the total revenue having risen from £196,882 in 1900 to £968,811 in 1909.

The Iron Industry of Elba.—A great increase in the output from the rich deposits of iron ore in the island has been made during the last few years, as will be seen from the following figures taken from a recent report issued by the administration of the Elban mines and metallurgical works. The introduction of modern plant and machinery for the working of the mines, as well as the treatment of the ore by up-to-date processes is now giving excellent results. There are about thirteen miles of railway with eight locomotives and 1,500 trucks for the transport of the ore from the various mines to the works and coast. Several lines of aerial rope transporters have also been constructed, and three others are nearly completed. The facilities for shipping the ore have been considerably increased during the last few years, and it is now possible to load vessels of larger tonnage than was formerly the case. 510,701 tons of ore were shipped last year as compared with 207,664 tons during 1909. The production of pig iron last year amounted to 156,004 tons, whilst that of Bessemer steel for the same period was 66,862 tons, as compared with 28,028 tons of the previous year.

International Silk Congress, Turin. — An international silk congress is announced to be held at Turin, on September 21st, 22nd, and 23rd, 1911, to which delegates from the various institutions and associations connected with the silk industry, the Chambers of Commerce, as well as persons connected with establishments for the "conditioning of silk" of all nations are invited. Other persons interested in the silk trade may attend, on payment of a fee of 20 lire (16s.) to cover the cost of printing, etc.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

May 10.—Hal Williams, M.I.Mech.E., M.I.E.E., "Beet-Sugar Factories." The Earl of Denbigh, C.V.O., will preside.

May 17.—Professor Raoul Pictet, "Les Basses Températures."

May 24.—Frank M. Andrews, "Architecture in America." Sir Aston Webb, C.B., R.A., F.R.I.B.A., will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

May 25.—W. R. H. Merk, I.C.S., C.S.I., LL.D., "The N.W.F. Province of India." The Earl of Minto, K.G., G.C.S.I., G.C.M.G., G.C.I.E., will preside.

Colonial Section.

Tuesday afternoon, at 4.30 o'clock:—

May 9.—F. Williams Taylor, "Canada and Canadian Banking." His Grace the Duke of Argyll, K.T., G.C.M.G., G.C.V.O., will preside.

Cantor Lectures.

Monday Evenings, at 8 o'clock:—

Alfred E. H. Tutton, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

Syllabus.

Lecture II.—May 8.—*The Internal Structure of Rock Crystal, and the Means we possess of Elucidating it.* The Chemical Molecules of Silica, and their Arrangement in a Space-lattice — The Influence of the Arrangement of the Elementary Atoms in the Molecule of Silica in Determining a Right or Left-handed Screw Structure—The probable Disposition of the Atoms and Molecules in the Right and Left Varieties of Quartz, and the Effect of this Internal Structure in determining the Outward Geometric Form—Revelation of the Oppositely Helical Structure by Etching and Liquid Cavities.

Lecture III.—May 15.—*Optical Evidence of the Two Complementarily Opposite (Mirror-image) Screw Structures.* Rotation of the Plane of Vibration of Polarized Light in Contrary Directions by the Two Varieties of Quartz—Experiments on the Artificial Reproduction of the Quartz Phenomena, in proof of the suggested Screw Structure—The Twinning of Quartz and Apparent Enhancement of the Symmetry and Destruction or Modification of the Optical Activity thereby—The Interesting Case of Amethyst—The Magnificent Polarization Phenomena of Twinned Quartz.

Lecture IV.—May 22.—*Scientific and Industrial Uses of Rock Crystal.* Its Thermal and Electric Properties, and its Transparency to Ultraviolet Rays—The Construction of Prisms and Lenses (including spectacles) of Rock Crystal, and their Advantages over Glass—The Use of Quartz

for Balance Weights and in connection with the Interferometer—The Artistic Use of Quartz for the Carving of Vases and other Objects—Destruction of the Crystalline Structure by Fusion, and the Uses of Fused Silica in Fibres and Scientific Apparatus.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 8...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. A. E. H. Tutton, "Rock Crystal: its Structure and Uses." (Lecture II.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Brewing, Institute of (Scottish Section), Caledonian Station Hotel, Edinburgh, 8 p.m. Mr. A. J. Heslop, "The Washing and Aeration of Barley."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. J. J. Done, "Development of Building Land."

Geographical, Burlington-gardens, W., 8.30 p.m. Mr. J. A. J. De Villiers, "Foundation and Development of British Guiana from Unpublished Documents."

Victoria Institute, 1, Adelphi-terrace House, W.C., 4.30 p.m. Professor F. F. Roget, "A Life Contribution to the Harmony of Christianity, Philosophy and Science."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Sir George Reid, "The Past, Present, and Future of Australia."

TUESDAY, MAY 9...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. F. Williams Taylor, "Canada and Canadian Banking."

Illuminating Engineers, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Annual Meeting.

Asiatic, 22, Albemarle-street, W., 4 p.m. Anniversary Meeting.

Royal Institution, Albemarle-street, W., 3 p.m. Mr. J. E. C. Bodley, "The Institute of France."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Mr. R. I. Pocock, "On the Palatability of Some British Insects." (Experiments made in the Society's Gardens with Arthropods (chiefly Insects) and Molluscs, and Notes on the Significance of Mimetic Resemblances.) 2. Professor Gilbert C. Bourne, "Contributions to the Morphology of the Group Neritoidea of Aspidobranch Gastropods. Part II. The Helicinidæ." 3. Mr. J. J. Lister, "On the Distribution in the Pacific of the Avian Family Megapodidæ."

WEDNESDAY, MAY 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Hal Williams, "Beet-Sugar Factories."

Biblical Archæology, 37, Great Russell-street, W.C., 4 p.m.

Geological, Burlington House, W., 8 p.m.

Automobile Engineers, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Mr. L. A. Legros, "The Use of Pressed Steel in Automobile Construction."

Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Mr. F. J. Hawkins, "Notes on Illumination by Gas and Electricity."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.45 p.m. Mr. R. W. Vawdrey, "Reinforced Concrete." (Lecture III.)

THURSDAY, MAY 11...Iron and Steel Institute, at the Institution of Civil Engineers, Great George-street, S.W., 10.30 a.m. Annual Meeting. 1. Messrs. Felix A. Daubinè and Eugène V. Roy, "Note on a Process for the Desiccation of Air by Calcium Chloride." 2. Mr. J. E. Stead, "On Welding up of Blowholes and Cavities in Steel Ingots." 3. Messrs. E. F. Law, W. H. Merrett, and W. Pollard Digby, "On Some Studies on Welds." 4. Dr. J. N. Friend and Mr. J. H. Brown, "On the Action of Aqueous Solutions of Single and Mixed Electrolytes on Iron." 5. Mr. Percy Longmuir, "On the Corrosion of Steel." 6. Mr. J. W. Cobb, "On the Relation of Impurities to the Corrosion of Iron." 7. Mr. E. Adamson, "On Temperature Influences on Carbon and Iron."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Roman Studies, Society for the Promotion of, Lecture Theatre, Burlington-gardens, W., 4.30 p.m. Inaugural address by the President, Professor F. Haverfield.

Royal Institution, Albemarle-street, W., 3 p.m. (Tyndall Lecture.) Professor R. W. Wood, "The Optical Properties of Metallic Vapours." (Lecture III.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Professor H. E. Armstrong, "Leaf Studies."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. J. S. Heather, "The Driving of Winding Engines by Induction Motors."

Architects, Society of, 28, Bedford-square, W.C., 8 p.m. Mr. A. Saxon Snell, "Hospitals."

FRIDAY, MAY 12...Iron and Steel Institute, at the Institution of Civil Engineers, Great George-street, S.W., 10.30 a.m. Annual Meeting. 1. Mr. H. C. H. Carpenter, "On the Growth of Cast Irons after Repeated Heatings. Parts II., III. and IV." 2. Messrs. J. O. Arnold and A. A. Read, "On the Chemical and Mechanical Relations of Iron, Chromium and Carbon." 3. Messrs. A. McWilliam and E. J. Barnes, "On the Influence of 2 per cent. of Vanadium on Steels of varying Carbon Content." 4. Mr. W. H. Hatfield, "On the Influence of Vanadium upon Cast Iron." 5. Messrs. C. H. Ridsdale and N. D. Ridsdale, "On Mechanicalising Analysis as an Aid to Accuracy and Speed for Commercial Purposes."

Royal Institution, Albemarle-street W., 9 p.m. Professor W. Stirling, "Biology and the Cinematograph."

Malacological, Burlington House, W., 8 p.m. 1. Dr. W. H. Dall, "Some Remarks on the Nomenclature of the *Veneridæ*." 2. Mr. G. B. Sowerby, "Description of a New Species of *Conus* from South Africa." 3. Rev. A. H. Cooke, "A Modification in the Form of Shell (*Siphonaria Algesiræ*) apparently due to Locality."

Astronomical, Burlington House, 5 p.m.

African Society, Trocadero Restaurant, Shaftesbury-avenue, W., 8 p.m. Sir H. Hesketh Bell, "Recent Progress in Northern Nigeria."

SATURDAY, MAY 13...Metals, Institute of, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8.30 p.m. Dr. G. T. Beilby, "The Hard and Soft States in Metals."

Royal Institution, Albemarle-street, W., 3 p.m. Professor Selwyn Image, "Walter Pater: or, the Connoisseur and Art."

Municipal and County Engineers (Midland District Meeting), Town Hall, Stratford-on-Avon, 11 a.m. 1. Mr. Roden Dixon, "Notes on Stratford-upon-Avon Municipal Work." 2. Mr. H. D. Bell, "General Description Sewage Disposal Works." 3. Visits to Municipal Works, etc.

Journal of the Royal Society of Arts.

No. 3,051. VOL. LIX.

FRIDAY, MAY 12, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

Monday, May 15th, 8 p.m. (Cantor Lecture.) Alfred E. H. Tutton, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." (Lecture III.)

Wednesday, May 17th, 8 p.m. (Ordinary Meeting.) Professor Raoul Pictet, "Les Basses Températures."

CANTOR LECTURE.

On Monday Evening, May 8th, Dr. Alfred E. H. Tutton, M.A., F.R.S., delivered the second lecture of his course on "Rock Crystal: its Structure and Uses."

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday Afternoon, May 9th, His Grace the Duke of Argyll, K.T., G.C.M.G., G.C.V.O., in the chair. A paper on "Canada and Canadian Banking" was read by Mr. F. Williams Taylor, London Manager of the Bank of Montreal.

The paper and discussion will be published in a subsequent number of the *Journal.*

CONVERSAZIONE.

The Society's Conversazione will be held, by permission of the Trustees of the British Museum, in the Galleries of the Natural History Museum, South Kensington, on Tuesday Evening, May 30th, from 9 p.m. to 12.

The Reception, by Sir John Cameron Lamb, C.B., C.M.G., Chairman, and the other Members of the Council, will be held in the Central Hall from 9 to 10 p.m.

A Selection of Music will be performed by the Band of H.M. Royal Artillery, in the Central Hall, commencing at 9 o'clock.

A Vocal and Instrumental Concert will be given in the Fish Gallery and a Miscellaneous Entertainment in the Shell Gallery, under the direction of Mr. Patrick Kirwan, commencing at 9.30 p.m.

The following portions of the Museum will be open:—

The Central Hall, containing cases of specimens illustrating Mimicry; Adaptation of Colour to surrounding conditions; Protective Resemblance; etc. Also specimens illustrating the Food of Fishes, and the Life History of the Eel (East of staircase).

The North Hall, containing the collection of Domesticated Animals.

The Bird Gallery, containing groups of British Birds and Nests; and in the Pavilion, at the West end, an exhibition of the Land and Fresh-water Vertebrate Animals of the British Isles.

The Fish Gallery, containing the Great Basking Shark, the grotesque Deep-sea Fishes (case 44), the Tunny (case 38), the Tarpon and Angler-fish (case 27), and the Lemon-Sole (case 30), etc.

The Shell Gallery, including a life-size model of a Giant Squid (Newfoundland), and of a Giant Octopus (California).

The East and West Corridors on the First Floor, containing the Okapi, African Antelopes, and Giraffes.

Light Refreshments will be supplied at Buffets in the North and South Corridors on the First Floor of the Museum, and at the end of the Bird Gallery.

Visitors travelling by the District Railway (or other underground railways in connection therewith) will be allowed free use of the company's subway, which leads from South Kensington Station direct into the grounds of the Museum.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. (These cards will be issued shortly.) In addition to this, a limited number of Tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5*s.* each, if purchased before the day of the Conversazione. On that day the price will be raised to 7*s.* 6*d.*

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the Offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

It will greatly facilitate the arrangements if members requiring additional tickets will apply for them at as early a date as convenient.

The Council reserve the right of stopping the sale of tickets or of raising the price, if it is found necessary, in order to restrict the number of visitors within reasonable limits.

Further particulars as to the musical and other arrangements will be given in the Programmes, which will be distributed on the evening.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A Meeting of the Indian Section was held on Thursday, April 27th, 1911, Sir Arundel T. Arundel, K.C.S.I., presiding.

The Chairman, in introducing the lecturer, said Sir Thomas Holland went to India in the year 1889 as a Fellow of Owens College, and joined the Geological Survey shortly afterwards. In 1903 he was appointed by Lord Curzon Director of that department, which post he held for six years, when he completed twenty years' service. Sir Thomas had held various other official appointments in India, and his work had met with the approbation of the Government, who had conferred upon him a knighthood. He had also been made a Fellow of the Royal Society and a Doctor of Science. He had, moreover, received a unique compliment from the commercial community of Calcutta and Bombay in being asked to sit for his portrait by the Hon. John Collier, in order that there might be a permanent record of his connection with India.

The paper read was—

THE TREND OF MINERAL DEVELOPMENT IN INDIA.

By Professor Sir Thomas H. Holland, K.C.I.E., D.Sc., F.R.S.,
Late Director, Geological Survey of India.

Introduction.

The purely descriptive aspect of mineral occurrences in India has been treated sufficiently for present requirements in a series of official publications issued during my term of office as Director of the Geological Survey.* In this paper, therefore, I propose to review only those facts that are essential for a fair discussion of the practical lessons to be derived from past developments. Being no longer tied by official reticence, I am free to initiate discussion on topics about which, like many other Indian questions, there is still much prejudice in this country, prejudice largely due to insufficient knowledge and imperfect appreciation of the serious changes which have recently occurred in the balance of economic, social and political forces. My object thus is frankly to provoke discussion, but in the firm belief that the attitude of the Government to mineral questions is one which will safely bear honest critical examination.

The average investor in this country still entertains a vague impression that the India of to-day is the India of the nineties, when the Government rules for the grant of mineral licences and leases were apparently likely, if not actually designed, to clean out the wheat of honest investment with the tares of speculation, and when violent variations in exchange made it impossible for the capitalist or mining venturer to be certain that even the face-value of his stock could be realised again in gold.

Stability of Exchange.

Two reforms which were of the greatest importance in the development of Indian mineral industries took effect in 1899. In May of that year a series of rules, prescribed by the Secretary of State during Lord George Hamilton's administration, were gazetted by the Government of India for regulating the grant of prospecting licences and mining leases in British

* "Review of the Mineral Production of India during the years 1898 to 1903" (*Records, Geological Survey of India*, Vol. XXXII., Part 1); *Imperial Gazetteer*, Vol. III., 1907, Chapter III.; "Sketch of the Mineral Resources of India, Calcutta, 1908"; "Review of Mineral Production during 1904 to 1908" (*Records, Geological Survey of India*, Vol. XXXIX.). References to papers on special minerals are given in these summaries.

India. In September of the same year, as the outcome of the Government policy of restricting the coinage of silver in the Indian mints, it became possible to declare a gold standard of currency, with a fixed exchange at the rate of 15 rupees to the sovereign. The new rules for granting mineral concessions removed most of the undesirable restrictions imposed by those that had been in force since 1894. The new stability of exchange made it possible for the English investor to be certain of the nominal value of his capital outlay, and of the worth of his dividends. Both reforms were, however, effected so quietly that for some years their reality was not fully appreciated, and even now the ordinary investor retains a vague impression that the policy of the Government of India is unsympathetic, if not inimical, to the interests of the mining venturer. The changing attitude of public opinion, in India and at home, with regard to the financial policy of the Government, has been demonstrated by Mr. Reginald Murray, in his paper on "Banking in India," which was read before this Society on January 19th last;* the other subject now remains to be examined.

Mining and Prospecting Rules.

One incident should be sufficient to illustrate the general ignorance and persistent prejudice recently prevailing with regard to the mineral policy of the Government of India. In 1904 one of the Members of the Viceroy's Council (who can be assumed to have known the general feeling of financial circles at home) recorded in the secretariat, as a simple, unqualified and incontrovertible statement, that the Indian rules for the grant of mineral licences and leases were generally recognised to be obstructive and calculated to prevent mineral development, and he accordingly called for an examination of the laws in force in the colonies. As the outcome of this demand, the most recent laws controlling mining enterprise in the colonies were gathered together, and compared with the rules now in force in India. It then became evident that the Indian rules framed by Lord George Hamilton were based largely on colonial legislation, but with limitations made evidently and purposely liberal, not only in regard to areas of concessions, but also in regard to rents, royalties, shapes of blocks and periods of tenure.

Nevertheless, complaints appeared from time to time, either regarding the nature of the rules, or the way in which they were administered by district officials. Although, naturally, only those who have grievances, real or fancied, make complaints, while the satisfied residue discreetly keep silent, it is evident that a certain amount of revision is now desirable, partly because of the way in which some of the rules, as at present worked, lend themselves to variety in their local interpretation, but mainly because of the industrial and economic changes which have occurred in India during the past ten years. While in charge of the Geological Survey, I invited owners of mineral concessions, prospectors and miners, freely to record their views regarding the policy indicated by the rules as well as regarding their local interpretation. As the outcome of correspondence and conversation with those who were thus really affected, I received abundant testimony regarding the generous nature of the rules as a whole, a certain number of specific complaints about the way in which they were applied by district officials, but only a few objections to the spirit of the rules themselves. It became increasingly evident, as the inquiry developed, that complaints of a general kind occasionally heard were due largely to the supposed survival of the objectionable features which made the old rules so obstructive. The returns of mineral concessions taken in Government lands year by year offer a partial demonstration of the beneficial effects of the revised policy of 1899. These returns are summarised in the accompanying table:—

TABLE I.

Summary of the Mineral Concessions granted in Government Lands during the Years 1899-1909.

Year.	Mining and Prospecting Licences.	Exploring Licences.	Total.
1899	47	13	*60*
1900	61	11	*72*
1901	89	15	*104*
1902	89	16	*105*
1903	84	16	*100*
1904	125	26	*151*
1905	145	44	*189*
1906	211	41	*252*
1907	539	61	*600*
1908	579	237	*816*
1909	550	143	*693*

* *Journal of the Royal Society of Arts*, Vol. LIX., February 3rd, 1911, p. 263.

These figures only partially reflect the activity of prospectors in India, for we have no complete returns regarding concessions granted in Native States and by the numerous zemindars, who own mineral as well as surface rights. Owing to a reason which will be obvious to any student of Indian history, Government lands are not those which are most conspicuously mineral-bearing; for the control of the old East India Company extended—let us charitably assume, by accident—over the areas most conspicuously rich in agricultural products, the value of the wealth below the surface being so completely overlooked by the Company officers that the minerals in Bengal, for instance, were ceded with the surface rights simply by a careless wording of the Permanent Settlement in the areas now known

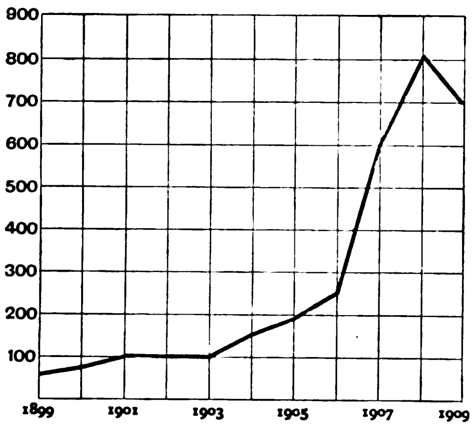

FIG. 1.

NUMBERS OF MINERAL CONCESSIONS GRANTED IN GOVERNMENT LANDS ONLY, 1899-1909.

to be so remarkably rich in coal. The annual returns for the grant of mineral concessions, however, show that the mineral policy of the Government, whatever may be its shortcomings, is capable of an immediate response to the activity of prospectors; for the rapid increase in the number of concessions granted between 1906 and 1908 is mainly due to licences and leases taken up to meet the temporary "boom" in manganese ore.

In 1908 the Government of India appointed a small committee, including representatives of the commercial community, to consider the question of revising the rules for the grant of mining concessions; and, as a consequence of the report of this committee, a certain number of modifications have now been proposed. Some of these, it is hoped, will meet well-founded complaints against the old rules; but, on the whole, the representations made by the mining community tend as much towards increased restriction as towards generosity of concession; for restrictions and safeguards are necessary, not only in the interests of the country as a whole, but for the protection of the real investor as opposed to the mere speculator. Increased stringency is required in defining boundaries of concessions applied for, to prevent unscrupulous pirates from "jumping" the claims of real prospectors, while regulations are required to enforce vigorous and continuous work in a workmanlike manner, to deal with those who do not blush to ask for concessions larger than they ever hope to work themselves. While the proposed new rules will probably favour the honest investor, they will be regarded as objectionable by the professional company promoter, who is sometimes more hopeful of exploiting metalliferous pockets through the Stock Exchange than those provided by Nature on land granted by Government for mining operations. Above all, it is hoped that the new rules will meet the numerous and often well-founded complaints against delays in dealing with applications for licences and leases. Purely administrative measures during the past few years have greatly reduced such delays, but they were in part due to a too literal interpretation by district officials of the rules themselves.

In addition to a number of minor changes, it is proposed to simplify the old system of requiring a Government certificate of approval with each application for a licence or lease. The working of the old rules in this respect was the most fruitful of all sources of delay in dealing with applications. It is proposed also to abolish Government control over the transfer of licences and leases, and a concession holder, therefore, under the new rule, may, when forming a company to work his concession, proceed with absolute certainty of being able to transfer his rights. The old rules for the grant of exploring licences will probably be abolished, as anyone in India is at liberty to search the surface of unoccupied and unreserved Government lands without a licence of any sort. The proposed rules, having been issued to all local governments, to the chambers of commerce, and to the mining associations, for criticism, have, in the main, met with general approval. The criticisms received are now under consideration before submission of the draft rules to the Secretary of State for sanction.

There is one conspicuous and serious defect, however, which for the present it is impracticable to remove. No general provision is made for

granting a claim on water-rights in areas leased for mineral working. To the miner, who knows that an abundant water-supply is necessary for most forms of mineral-dressing, this will be regarded as a serious drawback. It should be remembered, however, that in a country like India, where Native States and zemindaris are so dovetailed with one another and with British territory, it is impossible in general rules applicable to the whole Empire to guarantee water-rights in streams which cross various territories. Clauses granting, so far as is possible, claims on water are included in most leases, while in some cases it might be possible in future to frame special rules for certain provinces; but wherever the population is thick and other industries, from the nature of the country, predominate, only certain of the minerals less dependent on a large water-supply can be guaranteed by the Government this important advantage.

Progress in Mineral Production.

I propose now to give a general sketch of the progress recently made in mineral development, and then to make special reference to the most conspicuous among the products worked, but obviously nothing more than a brief outline is possible in a single paper. The accompanying diagram and table show the gradual increase

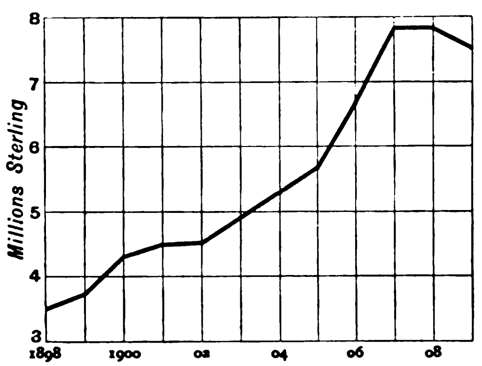

Fig. 2.

Total Annual Values of the Sixteen Principal Minerals Raised, 1899–1909.

in the annual value of those materials for which reliable and regular returns are obtainable. There are many minerals for which only partial and varying returns are obtainable; the table thus does not represent the real totals, but, as it includes the same minerals throughout the whole period, it fairly represents the rate of progress recently made, the increase in total value from 3¾ to nearly 7½ millions sterling being at the rate of just 100 per cent. for the period of eleven years. (Table II.)

TABLE II.

Total Values of the Principal Minerals Raised during the Years 1899–1909.

Year.	Total Value.
1899	£3,734,420
1900	£4,338,025
1901	£4,492,416
1902	£4,513,283
1903	£5,047,201
1904	£5,364,016
1905	£5,721,774
1906	£6,751,347
1907	£7,863,656
1908	£7,880,832
1909	£7,499,228

The values which contribute to the totals in Table II. are, in most cases, only pit-mouth *prices*, and are thus less than the actual market values. This feature brings out the most prominent and most serious defect in the nature of the Indian mineral industries. Minerals like manganese ore, mica, jadeite, chromite, and saltpetre, are raised almost entirely for export, and thus contribute to the industrial development of other countries which give, by way of compensation, to India only a fraction of the market value of the minerals, the freight charges to the areas of consumption being often greater than the pit-mouth values. The manganese-ore deposits are the most conspicuous among those which are being depleted without corresponding compensation to the country. Since the commencement of manganese-mining in India in 1892, the production has amounted to just 4½ million tons of high-grade ore, the whole of the mineral being sent out of the country. Taking into consideration the variations in price during the whole period, this product would be worth about 5½ millions sterling at Indian ports, and nearly 8 millions in the European market. Against this loss the Government and Native States between them have received in royalty not more than about £56,000, while a portion of the estimated value has been spent on labour and transport in India.

The loss to the country, however, is but imperfectly measured by the difference between the sale-value of the ore in the European market and the amount paid in India in the form of royalty and mining costs. The ore exported, being of high grade, would, if the metallurgical industries of India were developed, be largely converted into ferro-manganese on the spot, the excess beyond the country's requirements being then exported at a price about four times that of the ore. As India is a large importer of steel, the manganese purchased in this form has to pay the cost of transport to Europe and the manufacturer's profits, as well as the return freight. But even this is by no means a full measure of the economic disadvantage of exporting the raw material, for the ore contains only 50 per cent. of the metal, each ton of which therefore has to pay the freight on two tons; and, further, as in the process of manufacturing ferro-manganese there is a heavy loss of the metal in the slag and "fume," amounting possibly to 25 per cent., the whole of the tax falls on about three-quarters of the one ton.

So long as we are certain that India possesses more manganese ore than it wants, or ever will want, it is better to export the material for small profits than to allow it to lie idle in the ground. Even if one were certain that India in the distant future would be compelled to import manganese to meet the requirements of its steel industry, it might still be advisable to obtain as a certainty present profits, instead of allowing so much capital to lie idle. But within the next twenty or thirty years, when the richer visible deposits have been depleted, and the manganese miner has "picked the eyes out of the country," the question of exporting ore for the absurdly small rate of compensation now received will become a serious problem for the Government to face, whether it is free to exercise its worldly wisdom in the interests of India itself, or is drilled by Whitehall to conform to the fiscal policy of the party for the time being in power.

The next lesson of importance to draw from the general survey of production is the dangerous state of simplicity in the Indian mineral industries. In every economic system, as in every department of Nature, a simple system is always one which is in a condition of unstable equilibrium, easily upset on the slightest change in the balance of forces. For instance, a rise in the unit-price of manganese to a shilling yields profits to the Indian miner altogether out of proportion to the capital and risks involved, while a fall to eightpence would practically wipe out the whole industry of manganese-mining. Until metallurgical and chemical industries are developed in India, and as long as ores can be raised for export in the raw state, this dangerous state of uncertainty must exist, making it practically impossible to develop any minerals so situated that they can be exploited only by systematic operations incurring a considerable capital outlay. So long, therefore, as these unsatisfactory features of the industry persist, most of the so-called ore-mining in India must be limited to the mere quarrying of the easily accessible and visible deposits of grades sufficiently high to pay for the heavy charges of transport to distant markets. Such an industry, like the vegetation of a desert, is either in a state of rank and luxuriant growth during a favourable season, or is absolutely dead. The weak spot which is so conspicuous in Indian mining is similar in character to that of its agriculture, which depends still almost wholly on the monsoon and the natural fertility of the soil —years of prosperity alternating with years of famine, both being embarrassing, because practically the whole country is affected at the same time and in the same way.

The steadying influence of complexity in the mineral industries will not be possible until the requirements of the country include sufficiently large local markets for the various metals and for the smaller bye-products obtained during their exploitation. The trade returns show that these essential conditions are now gradually ripening, for the imports of metals, and mineral products have been gradually increasing. In 1909 the value of simple metals imported into India amounted to 8½ millions sterling. If we add to this the value of articles made from metals (which naturally cost more than the metals of which they are composed), we obtain a total of over 20 millions. In addition to the importation of metals, there is a large and growing trade in European inorganic chemicals and other mineral products, including sulphuric acid, soda and alum, amounting in value to over half a million sterling, in addition to artificial dyes of about the same value. Precious stones, building materials, and salt together add about another 1½ millions to the annual import bill. I have so far kept out of this statement the two substances, coal and petroleum, which are now being displaced by indigenous products. The imports of coal have been reduced to a small and fairly constant charge for special kinds only, having a total value of about half a

million, while the purchase of foreign mineral-oil has also been reduced during the past ten years from over 2½ to about 2 millions, the Indian consumption having risen at the same time in addition to a small export of kerosene and paraffin-wax from Assam and Burma.

Before the development of some metalliferous minerals can be successful there is, however, another condition, besides a large total market for the chief products, which must be satisfied. Metallurgical and chemical industries are essentially gregarious in their habits; they can flourish only in family groups large enough to utilise one another's subsidiary products, and each family group can survive only when there is a market for the smallest of its members, thus necessitating possibly a very large market for the principal products.

India at one time manufactured its own metals and inorganic chemicals; but, with the opening of the Suez Canal and with concurrent improvements in marine engineering, freight charges from Europe became so reduced that the European manufacturing chemist could "dump" his bye-products at Indian ports, and from there our growing network of railways has enabled the importer, either to kill the native industries altogether, or to drive them back to remote parts of the country.

In addition to the advantage gained by the economical recovery of bye-products, the European chemist has discovered among his inorganic chemicals agencies that do work precisely similar to that of the multitude of low forms of organisms which have hitherto given well-governed tropical countries a natural advantage in the growth of many products. There are certain so-called catalytic agents, such as platinum, ferric oxide, and copper chloride, which act as brokers in a chemical manufactory; they bring together elements to form commercially valuable compounds, which could otherwise only be made by the expenditure of costly energy comparable to that which we have in the great vital energy of the tropics. Unlike the ordinary middleman, these chemical agents work without commission. The unions temporarily so formed by catalytic agents are essentially analogous to the products of the short-lived organisms of the soil, and the manufacturing chemist has thus turned to commercial account in his attack on tropical products what has been aptly termed the chemically loose habits of his reagents.

He has, moreover, recently added another weapon to his arsenal by turning water-power into electric energy; and, as a consequence of all these developments of science, we find that natural products growing wild in the tropics are being displaced, even in their own homes, by material manufactured in Europe, where chemistry has overcome the disadvantages of climate. Two striking examples are sufficient to show this strange reversal of trade. Indian imports of refined sugar from the continent of Europe are now valued at nearly a million sterling per annum. Ten years ago India exported indigo to the value of 1¼ millions; by 1909 the exports of indigo had dwindled down to just one quarter of this value.

The conclusion to be drawn from these alarming facts ought to be, however, reassuring; for what science can do in Europe with climatic drawbacks, it should be able to do with the assistance of tropical advantages. But the statesman who realises this conclusion must realise also that, while the principles of science are the same all the world over, the methods by which they are applied in Europe are not those that will be successful under tropical conditions, and their modification to suit the special conditions of India can be discovered only by research in India itself, with Indian natural products tried under Indian conditions. In the recent cry for the application of technical science to India, it has often been forgotten that methods and men suitable to Europe are not necessarily suitable to India; it has been forgotten that Indian students sent for training in Europe must return with the handicap of a false impression; it has been forgotten that the discovery of special methods suited to the conditions of the country, and the development of new habits among workers do not follow suddenly from the issue of a Government order, nor are they effected in a single generation. Nothing could so strikingly demonstrate the imperfections of our system of education by copybook headings as the recent advocacy by educated Indians of resolutions against the purchase and use of foreign goods. Among the advocates of the "boycott" have been men who are capable of handling as experts the jargon of political economy, but who are so far ignorant of their practical effects as to overlook the fundamental fact that trade, like a galvanic current, requires an unbroken circuit; favourable freight rates for export from India are obtainable only because of the ships being employed also for imports; and every effective demonstration against foreign goods, therefore, merely adds another handicap to the native producer of raw material.

The Principal Minerals.

In selecting special minerals for consideration, I will confine myself to a few prominent examples in each of the two great classes—those that have been rapidly developed, and those that have been neglected altogether. The lessons obtained in both cases are complementary.

Of the minerals for which we have regular and fairly accurate returns, the order of annual value is :—Coal, gold, petroleum, manganese ore, salt, saltpetre, mica, jadestone, ruby, iron ore, graphite, tin ore, chromite, diamonds, magnesite and amber. Unfortunately, we have no statistics by which to measure the production and consumption of building materials, although an annual estimate of these would give even a more faithful curve of industrial progress than the census of the population. In ordinary and ornamental building stone India, and especially Peninsular India, is remarkably well endowed. It is to the abundance and excellence of ornamental building stone as much as to the genius of the people that every ruling dynasty before the advent of the British owed its fame for architectural monuments. Until Lord Curzon scattered some germs of artistic taste, British official buildings in India were constructed mainly of brick, and in a style that has yet to receive a name in the literature of architecture.

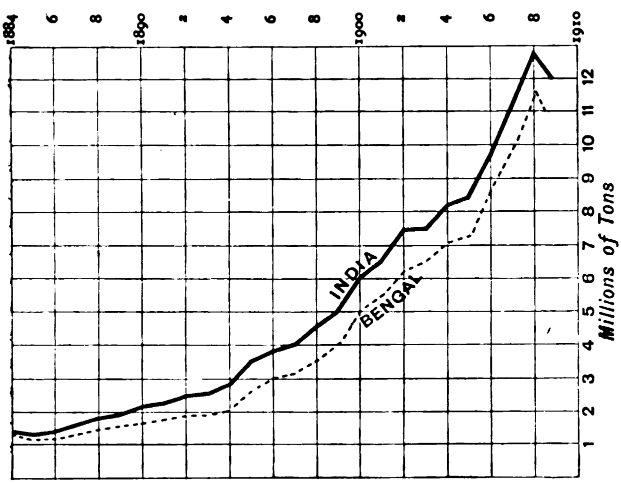

Fig. 3.—Annual Output of Coal since 1884, showing the Share Contributed by the Bengal Coal-fields.

Of the remaining mineral products, coal, petroleum, salt, and iron ore are the most important, because they are consumed in the country and thus contribute to progress in other directions beside simple mining. I propose to consider these four minerals in the first instance, and then to discuss the most important among those raised for export.

Coal.

The production of coal has risen during the past twenty-five years from 1½ millions to just 12 million tons a year. Each year, except the last, has shown an increase on its predecessor, while in 1906 and 1907 there was a sudden rise in production. As usual with all forms of industrial and financial inflammation, known familiarly as "booms," this excess was followed by a setback, and in 1909, for the first time, the upward trend of the curve became interrupted. The production for 1909, however, exceeded that for 1907, and probably represents a figure closely approaching a point lying on the curve of healthy development. From this point we may expect the rise to continue with the general expansion of coal-consuming industries, the workers as well as the share manipulators having received a lesson which will be appreciated for the few years over which the public memory usually lasts.

The only coal of value in Peninsular India occurs in the lower division of the great system of freshwater deposits known as the Gondwana system. These Lower Gondwana beds are divided into two series—Talchir and Damuda The Talchir, or basement, series of the Gondwanas contain no workable coal. The coal-bearing Damuda series is divided, in the eastern coal-fields, into three stages as follows :—

1. Barakar stage.
2. Ironstone shales.
3. Raniganj stage.

The middle stage has been worked in the Raniganj field by the Bengal Iron and Steel Company, who have now nearly used up in their blast furnaces at Barakar the visible supply of clay-ironstone. The other two stages are the chief sources of coal, the older, or Barakar stage, being the more important in the Giridih and Jherria fields, while both have been freely worked in the Raniganj field.

About the best coal in the peninsula is that obtained from the lowest seam worked by the East Indian Railway Company in the Giridih field, where the coal sometimes shows on assay under 6 per cent. of ash and has a calorific value

of about 8,000 units. According to an estimate made by Dr. W. Saise in 1894,* the Giridih field then contained 82½ million tons of available coal, and of this nearly 12 million tons have since been produced, leaving little over 70 million tons as roughly the amount still obtainable.

Numerous assays have been made of the samples taken from the seams being worked in the Jherria and Raniganj fields. Probably the results which most fairly represent the nature of the coals being marketed are those obtained by Major F. C. Hughes, of the Calcutta Mint.† These figures confirm previous results‡ in indicating that the coal in the lowermost Barakars differs from that in the Raniganj stage in containing less moisture and less volatile hydrocarbons, with a proportionately higher percentage of fixed carbon. There is a similar difference, less in degree, between the lower and upper seams in the Raniganj stage. The following table shows the average results which I have worked out from the figures published by Major Hughes:—

	Moisture.	Ash.	Volatile Matter.	Fixed Carbon.	Calorific Value.	
					Calculated.	Determined.
Raniganj (24 samples) .	4·50	9·73	32·03	53·74	6864	6828
Barakar (31 samples) .	1·22	11·04	23·76	63·98	7536	7331

developed. In these areas the percentage of moisture is generally as high as 12, with about the same percentage of ash, and thus nearly a quarter of the coal reduces instead of increases its calorific value. The calorific value of coals of this class from the Central Provinces will generally range around 6,000 units, as against 7,500 for Bengal coals from the Barakar stage, and about 6,900 for the Raniganj stage. No explanation has been offered for this extraordinary percentage of moisture in the coals south of the Satpura Range; no indication, therefore, can be given as to the prospects of the coal improving in this respect at greater depths.

The coal being worked in the Mohpani field at the northern foot of the Satpura Range in the Central Provinces conforms more nearly to the Raniganj type of the Bengal coal-fields in having only from about 2 to 5 per cent. of moisture; and, in spite of the slightly higher percentage of ash, the Mohpani coals show on an average a slightly higher calorific value than is obtained for the seams exposed to the south of the Satpura Range. Most of the coals in these fields are either non-coking, or, at best, produce a poor, friable coal. They, however, find a ready market for steam purposes among the cotton presses and factories of the Central and United Provinces.

In thirty-one samples of Barakar coals the volatile hydrocarbons amounted on an average to 27 per cent. of the total combustible constituents, while in twenty-four samples of coals from the Raniganj stage this percentage is found to be about 37.

In the Central Provinces, coal, of the same age as that worked in Bengal, contains an extraordinary amount of moisture, which seriously depreciates its calorific value. A very high percentage of moisture was shown by all the coals from the old colliery at Warora, which was abandoned in 1906; in the new field now being opened up at Bellarpur in the Chanda district, and in the Pench Valley field of the Chhindwara district, which is being rapidly developed.

It is certain that the Pench Valley field especially will develop at a much more rapid rate when the field is crossed by a broad-gauge rail connection between Nagpur and Itarsi. At present the only railway outlet for the field is by a narrow-gauge line, which reaches the two great broad-gauge systems—the Bengal Nagpur on the south and the Great Indian Peninsular on the north—by the longest route possible. To transport coal from Chhindwara to the factories of Nagpur by rail necessitates a journey of 184 miles on a narrow and 80 miles on a broad-gauge line, involving obviously a rehandling of the coal in the middle of the journey. In the same way, transport from the Chhindwara field to any of the large towns on

the northern system of broad-gauge railway involves 180 miles of narrow-gauge, with a rehandling of the coal at Jubbulpore. A through broad-gauge line from Nagpur to Itarsi would bring the field within about seventy miles either of the great consuming centre of Nagpur, or of the main junction for the still larger markets in the north-west, and the change of gauge would thus be avoided. As this route will tap also a rich cotton-producing country, as well as the principal manganese mines, and will connect the capital of the Province with the great trade route of the north-west, the delay in its construction indicates a policy in railway development that cannot at any rate be regarded as over-enterprising.

By far the largest fraction of Indian coal is obtained from these Gondwana fields in the peninsula, the percentage contribution to the total output having risen gradually during the past ten years from about 93 to a little under 97 per cent. Most of the increase is due to activity in the two fields nearest Calcutta, Raniganj and Jherria. The Raniganj field up to fifteen years ago was the premier field; but, as soon as railway extensions were pushed into the Jherria field, the latter became rapidly opened up, its production having increased by over six times during the past ten years, and now amounting to about half the Indian total, while Raniganj contributes just one-third of the total. The remarkable development of Jherria immediately after the introduction of the railways offers a good illustration of the direct relationship between railway enterprise and industry.

In extra-peninsular areas, that is, in Baluchistan, the Punjab, Assam and Burma, the coal raised is almost entirely of Tertiary age. These coals, on the whole, differ from the Gondwana coals in containing a larger proportion of volatile hydrocarbons, though they vary greatly in composition and in thickness of seam. The deposits most largely worked are those of north-east Assam, where the coal occurs in seams of great thickness, with a remarkably low percentage of ash and a high calorific value. The composition and quality of these coals have been discussed by Professor W. R. Dunstan in a paper read before this Society in 1902.*

The quality of the coal obtainable from north-east Assam is shown by the following assays of samples more recently obtained by Mr. R. R. Simpson, from the collieries being worked near Margherita by the Assam Railway and Trading Company:—

	Upper Ledo.*	Tikak.†
Moisture	1·80	2·09
Volatile Hydrocarbons .	40·15	37·25
Fixed Carbon	55·59	58·99
Ash	2·46	1·67
Total	100·00	100·00

The development of the thick seams of high quality in this field is limited by the market, which locally includes the comparatively small wants of the tea-gardens, railways, and the steamers on the Brahmaputra. Expense of transport cuts off the large market of Calcutta, and though the coal itself, which is friable and liable to spontaneous combustion, is not easily carried for long distances, the perfect coke which it yields would be valuable with lower freights. The annual production of this field remains steadily at about 280,000 tons, while the total annual output of all the Tertiary fields in Extra-Peninsular India is only about 400,000 tons.

Colliery Labour.

Beside the mere financial and commercial results obtained, it is important to criticise the mining industry in its bearing on the well-being of the 120,000 persons employed at the collieries, as well as the larger number of their dependents.

During the past ten years the average number of deaths from colliery accidents in India has been 95 per annum, or at the rate of only 0·93 per thousand persons employed at the collieries. This figure compares favourably with the corresponding results for coal-mining in other countries. For the whole of the British Empire the death-rate from accidents at coal-mines ranges around 1·4 per thousand persons employed; while in the United Kingdom alone, where the labour statistics are sufficiently large to control the average for the whole Empire, the death-rate from colliery accidents has remained steadily, for the last few years, near 1·3 per thousand, a rate which has been exceeded during one year only in India, namely in 1908, when a serious accident in the colliery owned by

TABLE III.

LABOUR STATISTICS AT INDIAN COLLIERIES.

Year.	Number employed daily.	Tons of Coal raised per person.	Deaths from Colliery Accidents.	Deaths per 1,000 Persons Employed.
1900	89,248	69	*62*	0·69
1901	95,318	70	*70*	0·73
1902	98,312	75	*76*	0·77
1903	88,530	84	*97*	1·10
1904	92,740	89	*67*	0·72
1905	89,995	93	*72*	0·80
1906	99,138	99	*99*	0·99
1907	112,502	99	*101*	0·89
1908	129,173	99	*178*	1·37
1909	119,546	99	*128*	1·07
Average	*101,450*	*89*	95	*0·93*

one of the State railways at Khost in Baluchistan had a disturbing effect on the average.

The Indian figures compare still more favourably with statistics for foreign countries. In 1907 the average for all non-British coal-mining countries was 2·97 deaths per thousand persons employed, and in 1908 the corresponding figure was 2·34. The principal contributor to the higher death-rate in foreign countries is always the United States, where nearly 3,000 colliers are killed every year, with a death-rate always over three per thousand persons employed.

The remarkable safety of Indian mines almost removes the occupation of the collier from the class of "dangerous" occupations, the death-rate from accidents being lower than that at any class of mines, or even at quarries, in this country. To a large extent the satisfactory figures are due to certain natural advantages in the principal coal-fields of Bengal, where the majority of the workers are employed. In these fields there is such a general freedom from gas that only in a few mines are safety-lamps considered to be necessary, while the coal-bearing strata are so little disturbed by earth-movements that a natural roof can be relied on without timber in most galleries, even in those of much wider span than the galleries commonly worked in England. The mines are comparatively shallow, no shaft at present being more than 900 feet in depth; consequently, there is a small overburden to be maintained, and less danger from the "creep" due to earth pressures.

I think also that every coal-mine manager in India, who has had his training in the United Kingdom, will admit that the satisfactory state of affairs in Bengal is partly due to the careful habits of the collier himself, who, in spite of his ignorance of the principles which govern safe mining operations, retains so far a sense of discipline that has now been all but destroyed by our education authorities in this country. Nevertheless, there are indications that in India also the increased complexity of operations, which naturally follows the deepening of the mines and general extension of the workings, is adding to the dangers to which the collier is exposed. The annual rates for the last ten years range between 0·69 and 1·37 deaths per thousand persons employed; the lowest rate being in 1900 and the highest in 1908, while during the last five years the death-rate has averaged a little over 1·0 per thousand employed. It is possible that the higher rate during the past few years is a purely fortuitous agreement with our expectations from a knowledge of the gradually-increasing difficulties of mining, for with totals so small a serious accident, like that which occurred at the Khost mines in June, 1908, makes a notable mark on the record for the year. This accident having occurred in a Government mine, those prophetic critics who anticipated disasters as the result of the feverish

haste in raising coal to meet the "boom" of 1907 cannot point to the statistics as a certain fulfilment of their expectations. One must admit, however, that although haste in mining may not reveal itself at once in the labour statistics, for many years following the effects may result in loss of both men and material.

The statistics for mines under the control of the Government inspectors, who administer the Indian Mines Act of 1901, compare favourably with those in the Native States. During the past five years the death-rate from colliery accidents in Native States has averaged 1·4 per thousand persons employed, against an average of 1·0 during the same period for mines in British India. Before drawing any inference from these figures it is necessary to remember that the largest employer of labour among collieries in the Native States, namely, the Hyderabad (Deccan) Company, works its collieries in an area geologically more disturbed than the Bengal coal-fields, while the work in the Bikanir State of Rajputana, although on a scale too small to disturb the averages, is also carried on under unfavourable natural conditions. The average death-rate for the Singareni colleries in Hyderabad has been 1·55 per thousand for the past five years, a comparatively high figure, which is partly counterbalanced by the remarkably low rate of only 0·35 per thousand at the Umaria collieries in the Gwalior State of Central India. The unfavourable figures for Native States are thus due mainly to the returns from Hyderabad, where, as I have already explained, mining conditions are less simple than in Bengal.

A much more serious problem than that of ordinary mining accidents is due to the changes in population around the coal-fields, where the workers and their families, mostly derived from aboriginal tribes accustomed to the free life of the sparsely-populated jungle, are being crowded together, with an environment to which they are accommodating themselves by considerable loss of life. The simplicity of the lives and habits of these peoples, like that which I have already referred to as the nature of our mineral industries generally, lends itself to manifest dangers, and the growth of the coal-mining industry has been so rapid in the two principal fields that the colliery owners have been unable to make sufficient provision to prevent dangers which they now realise as financially serious. The questions of sanitation and water-supply have been forced recently on the colliery owners by serious cholera epidemics, and a concerted move for reform is now being actively organised, mainly through the public-spirited action of Mr. R. P. Ashton, of Messrs. Kilburn & Co., whose presidential address to the Mining and Geological Institute at Calcutta in January last deals very sympathetically with this serious problem. The recent halt in the rapid progress of Indian coal-mining has given the owner time to review his methods of work, and the result will be increased economy in handling his possessions of saleable mineral, as well as more thought for the health and happiness of his miners. Everyone, however, who has had experience of both countries, will admit that the average Indian collier is a far happier individual than his caste-fellow in England.

Coal Consumption.

The coal-consuming industries may be considered in two divisions, namely, the railways in one, and all other forms of coal-consumers in the other. Up to about ten years ago a serious fraction of the coal consumed on Indian railways was imported; from that time onwards foreign coal has generally varied between only 1 and 2 per cent. of the total supplies. The ratio, therefore, between the consumption by railways and the consumption by various industries in India forms roughly an index to the industrial expansion generally. During the past ten years, although the production of coal has been doubled, there has been a very steady and constant relationship between these two forms of consumption.

From Table IV. it will be seen that the railways have taken very nearly 30 per cent. of the total Indian output, and that the variation has been confined within the very narrow limits of 28·2 to 31·7 per cent. The remarkable constancy in this proportion, in spite of the great change in the total, at first sight seems to be inexplicable; but, so far as I can see, there is one simple lesson to be learnt from this interesting result, namely, that the industrial expansion of India is directly dependent on, and limited by, the railway expansion. The first conclusion drawn from these facts shows that the Government policy with regard to railways has, at any rate, followed safe lines; whether the policy has been, on the whole, unnecessarily conservative is another question. There is an interesting record of correspondence in the Geological Survey Office at Calcutta, between one of my predecessors and the Government of India in the late fifties. The Director of the Geological Survey urged on Government the extension of the East Indian Railway to the northern parts of the Raniganj coal-field; and

TABLE IV.

COAL CONSUMED ON THE INDIAN RAILWAYS.

Year.	Indian Coal.			Foreign Coal.		Total Consumption.
	Quantity.	Per Cent of Total.	Per Cent. of Indian Output.	Quantity.	Per Cent. of Total.	
	Tons.			Tons.		Tons.
1900	1,855,610	97·2	*30·3*	54,339	2·8	*1,909,949*
1901	1,956,601	99·3	*29·5*	13,248	0·7	*1,969,849*

1909	3,689,093	98·0	*31·0*	76,221	2·0	*3,765,314*
Average	2,673,854	98·63	*29·76*	39,041	1·37	*2,712,896*

in his attempt to produce an impression on Government, his enthusiasm led him to believe that it would pay in the long run to push the railway north-westwards even as far as Benares! At that time the East Indian Railway extended for 120 miles from Howrah to Raniganj, while the Great Indian Peninsular Railway joined Bombay to Thana, a distance of 21 miles, both these short lines being regarded as experimental innovations, preparing the way for the greater policy outlined by the far-seeing statesmanship of Lord Dalhousie, to whose minute, written in 1853, we can trace the policy of constructing the great trunk lines to connect the Presidency capitals. It is, perhaps, easy for anyone with special and local knowledge to point to instances in which the Government policy has been unnecessarily cautious; so far as the coal trade goes, one can say with fair safety that, at any rate, there is no indication of Government having erred on the side of reckless enterprise; for, as I have pointed out, the percentage of coal consumed on the railways as an index of industrial expansion has remained perfectly steady.

The yearly variations in the figures for imports of foreign coal, and exports of Indian coal, have been too limited to have any great significance. One change, however, has occurred which is noteworthy, for it coincides with the general utilisation of Indian coal on the railways since ten years ago. Up to the financial year 1899–1900 the imports of foreign coal exceeded

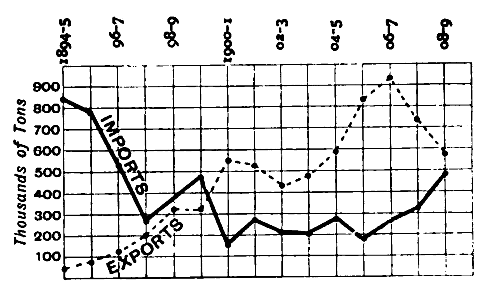

FIG. 4.

ANNUAL IMPORTS OF FOREIGN, AND EXPORTS OF INDIAN, COAL FOR FIFTEEN YEARS.

the exports of Indian coal; in the following year the relationship was reversed, and since then the imports have been generally limited to small quantities to meet local and temporary variations in the demand for special coals, while the exports have on an average been over half a million tons per annum, with a slight tendency towards increase during the last few years. The available foreign markets for Indian coal are, however, comparatively small, for the principal consumption around the Indian Ocean, within

striking distance of the country, is due mainly to locomotive wants.

Petroleum.

The development of petroleum, like that of coal, has given results that ought to satisfy the most exacting political economist. Practically the whole of the crude material is converted on the spot into refined products, and thus, whether consumed in the country or exported, is turned to full account. The growth of the petroleum industry forms one of the most interesting chapters in the development of Indian minerals.

The belt of Tertiary rocks forming a great arc stretching from the north-west corner of the Himalaya, through Baluchistan and Persia, to the famous fields of south-east Russia, show signs of oil at various places. A series of folds approximately similar in age stretches away in arc-like fashion from the eastern end of the Himalayan belt, with a general southerly trend through Assam and Burma, to the oil-bearing Tertiary rocks of Sumatra, Java, and Borneo.

In spite of the numerous "shows" of oil in Baluchistan and the Punjab, no serious or continuous exploitation has been so far accomplished in this part of the Indo-Iranian oil-bearing arc. In the Assam and Burma section of the eastern arc oil has been developed within a small area in the north-east corner of Assam, where the annual output has ranged around three million gallons for some years, and in Upper Burma, where the development has been limited practically to three fields, known as the Yenangyat field in the Pakokku district, the Singu field further south in the Myingan district, and the Yenangyaung field along the same line of folds in the Magwe district. Of these three, the Yenangyaung field, which has been exploited for many generations by native well-diggers, has always been, and still is, the most productive.

The development of the Yenangyat field began on a serious scale no further back than 1891, through the enterprise of the Burma Oil Company. The output rose slowly till 1894, and thereafter more rapidly until it reached a maximum of 22½ million gallons in 1903. From that year it has steadily declined to an output of a little over 6 million gallons in 1909.

The Singu field sprang into prominence in 1902, reaching an output of over 5½ million gallons in the following year, with a still more rapid rise to 23½ millions in 1904, and since then to a maximum of 43½ millions in 1907. The output of this field still exceeded 43 million gallons in 1908, but dropped to 37 millions in 1909. The diminished production during this last year is not, however, a reliable indication of failing resources; for the companies concerned have, by force of competition, devoted their main energies to the small but exceedingly rich area originally reserved by Government for the benefit of the native well-diggers in Yenangyaung.

This small section of the Yenangyaung field, known as the Twingon Reserve, has yielded the principal fraction of the field's output, which has risen during the past twenty years from under 10 to over 187 million gallons of crude oil. The operations in this field from an economic point of view are of such an interesting kind that they merit more detailed consideration.

For many years before the annexation of Upper Burma in 1885 the sole right to dig for oil in the Yenangyaung field was vested in twenty-four persons known as *twinzayos*, this right, or as it was called, the *ayo*, being hereditary. Each *twinzayo*, however, had the power to sell his *ayo* with the consent of the other twenty-three members of the guild. He or she—for the *ayo* sometimes descended through the female line—had the power to allot sites for oil-digging, each site extending to a distance of about 60 feet from the edge of the well in all directions. The *twinzayos* as well as the *twinzas*, or native well-diggers to whom sites had been allotted or sold, were obliged to sell all oil extracted at a fixed price, well below its market value, to the King's contractor. On taking over Upper Burma the Government of India recognised the hereditary rights of the *twinzayos*, and they permitted the *twinzas* to sell their oil in the open market, as well as to alienate their digging rights to whom they pleased, the Government taking a fixed royalty equivalent to eightpence for every forty gallons of crude oil extracted. In place of the old ill-defined practice of granting further well-sites to the *twinzayos*, the Government demarcated two reserves in what was apparently the rich parts of the field, and within these reserves each *twinzayo* was granted annually a regular number of well-sites. According to the "Executive Instructions" sanctioned in 1893, these sites were not to exceed one-fifth of an acre in area; but, in applying the sanctioned rules, a local custom arose, or rather was continued from the pre-British days, of requiring only an interval of 60 feet between the centres of the sites. As a consequence, the sites granted were about one-fourteenth, instead of one-fifth of an acre, and in this way the whole of the land available for oil-winning in the reserves became divided into thousands of small sites.

The *twinsa*, with his hand-dug well, can exploit only the shallow oil-sands; even with the assistance of a diver's equipment introduced in late years, his operations do not extend below 300–400 feet. As, however, there is nothing in his grant to prevent the site being sold for any purpose and to any person, the purchase of sites by the Burma Oil Company for deep drilling opened in 1896 a new chapter in the history of the fields.

in value to as much as £3,000 and £4,000. As the wells drilled proved to be so uniformly successful in the central and southern part of the Twingon Reserve, a veritable forest of derricks began to arise. In consequence of the small area of the individual sites, with American drillers exploiting the deep and gassy sands, while the *twinzas* between the derricks continued modestly to bail out oil from the upper beds, serious risks of fire were incurred.

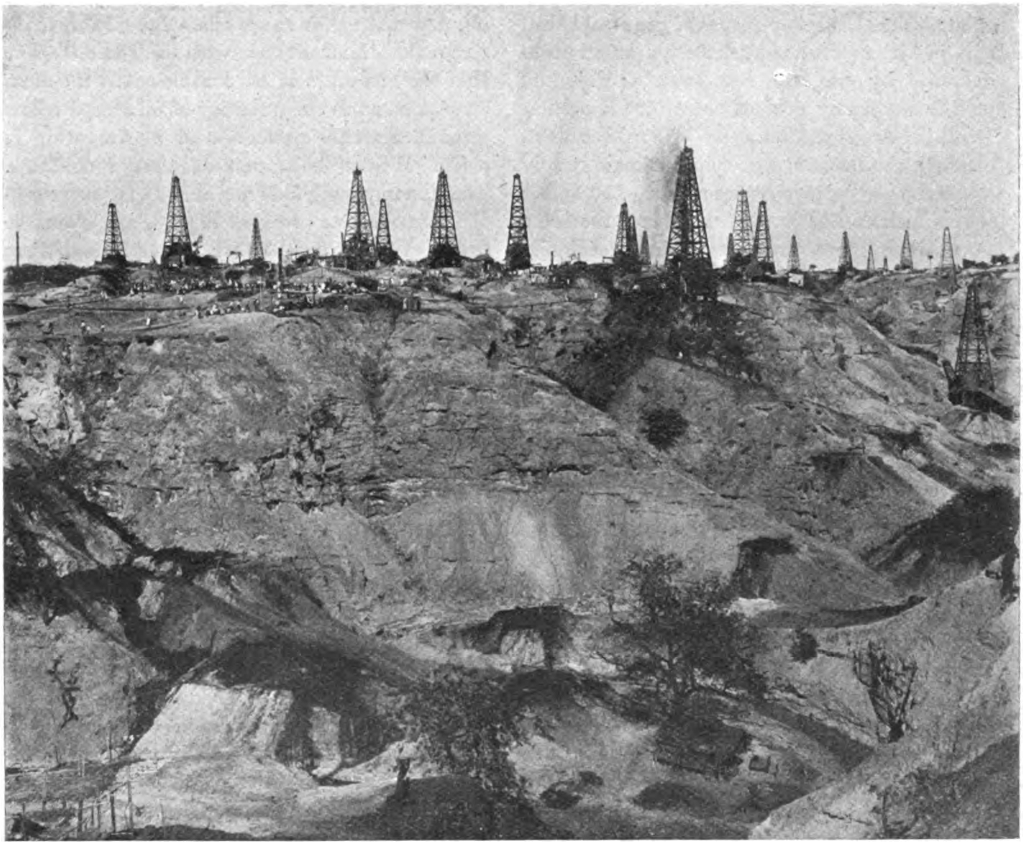

Fig. 5.—Yenangyaung Oil-field, Upper Burma.

View of Twingon Reserve from Khodaung, showing gushing well and, in the foreground, a characteristic deep gorge with some native hand-dug wells of the Twinzas.

Photograph reproduced by permission of the Burma Oil Company.

With the threatened intrusion of competing companies ten years ago the market price of well-sites within the reserves rose rapidly from under about £7 to about £200. At the end of 1906 the Rangoon Oil Company, which had been previously working in the Yenangyat field, also secured leases of well-sites in the reserves from the *twinzas*. The success which followed their operations tempted other companies, with the result that sites in the richest areas rose rapidly

In consequence of the feverish haste with which the competing companies rushed for the richer oil-sands, there was the danger of imperfect precautions being taken to keep the subterranean water out of the productive oil-sands, while possibly there was some danger also of imperfect exploitation of the resources.

In 1908 the Government appointed a Committee to make a careful investigation of the complicated circumstances which had arisen in

consequence of this alienation by the *twinzas* of small well-sites to European companies for drilling. The Committee found that there was, as anticipated, a serious danger of fire, due to the congestion of derricks with free-flowing wells of gassy oil interspersed among the native hand-dug wells. The new state of affairs had developed so rapidly that there were no regulations framed, either by Government or by the companies themselves, for the purpose of safeguarding the valuable field. The Committee found also that, in consequence of the established right of the *twinza* to alienate his small well-sites, site by site, no new system of tenure could be equitably devised to enforce a greater interval between producing wells than sixty feet. Although the *twinzas* were selling sites formerly regarded as expensive at from £5 to £10 apiece for as much as £4,000, and were thus receiving many times more than the values originally contemplated when the system of tenure was sanctioned, it would obviously be inequitable to adopt any new system which would depreciate even slightly or temporarily the market value of the sites. Similarly, it was found to be impossible to rearrange the holdings of the European companies, by exchange of sites for the purpose of forming larger blocks, as there were no data by which to form any idea of the great local variations in the values of different parts of the field.

The Committee consequently were forced to propose a series of regulations to mitigate, so far as possible, the dangers due to a confessedly unfortunate system of granting small holdings. The proposals made, after criticism by the companies and *twinzas*, were embodied in a Regulation passed last year by the Legislative Council of Burma. According to this Regulation, known as the Upper Burma Oil Fields Regulation of 1910, the field is placed under the control of a Warden, who has the power of a Magistrate of the first class, and is deemed a Revenue officer within the meaning of the Upper Burma Land and Revenue Regulation of 1889. Consistent with the new Regulation, detailed rules are issued defining the powers of the Warden, describing the manner in which well-sites are to be demarcated, the manner in which hand-dug wells are to be protected, the nature of regulations regarding the access of persons not employed in the work of oil-winning, the methods for measuring the oil produced, the precautions to be taken for the prevention and extinction of fires, the precautions to be observed to prevent the flooding of oil-sands by water, and regulating rights of way and transport. The new Regulation in many ways adds to the cost of oil-winning, but it has been recognised by the oil companies as a desirable form of insurance.

It is impossible ever to predict the trend of development in an oil-field, for there is absolutely no way by which an estimate can be made of the total resources of any field. The geologist is able to recognise certain stratigraphical features that are *favourable* for the storage of oil, but there are more fields favourably constructed without oil than with it. The mere fact that the structure is favourable gives no more exact idea as to the quantity of oil stored below ground, than the perfection of workmanship in a safe indicates the amount of money it contains. The Yenangyaung field has already far surpassed the expectations of every expert, and even the hopes of every speculator; nevertheless, there must be a limit to the quantity of oil available for exploitation, and no one has a right to expect that the heavy drain now occurring within a few acres in the centre of the field can last for many more years. Signs of exhaustion have appeared already in the upper oil-sands, and the drills are now seeking new reservoirs at greater depths. No one knows when the inevitable end will appear, and, unless other productive fields be discovered, the collapse of the Burma oil industry will be described more accurately as sudden than rapid. The Yenangyat field, which gave rise to great hopes ten years ago, has proved to be most refractory. On account of its topographical features, it is an expensive field to work, and the topographical features being partially an expression of complicated structure below, it is difficult to locate wells in it with any assurance of success. Singu is certainly capable of a greater output than the production figures show, and it must be regarded partly as a reserve to tone off the rapid fall which will otherwise follow the exhaustion of the Twingon Reserve in the Yenangyaung field. The rest of Burma may be summed up in one sentence: there are numerous occurrences of rocks similar in age to those which are productive in the three principal fields; in many cases these show a suitable stratigraphical structure for oil-storage, but so far not one among them has paid the expenditure incurred in prospecting.

The only area, in addition to Singu, that can now be looked upon as a satisfactory reserve is that known as the Khodaung tract in the Yenangyaung field. In structure the Khodaung is a replica of the rich

Twingon Reserve; it is, in fact, the other half of the dome, whose summit is very near the dividing line between the Twingon Reserve on the north, in which so many companies and *twinzas* are scrambling for a share of the oil, and the Khodaung to the south, which is held by the Burma Oil Company.

In this area (the Khodaung) the Burma Oil Company has wisely limited its drilling operations in depth, and has placed the wells sufficiently far apart to prevent, so far as can be judged, mutual interference. It is probable, almost certain in fact, that some of the oil being drained off from near the southern border of the Twingon Reserve comes across underground from the Khodaung area, and to this extent the property held by the Burma Oil Company is being depleted by their competitors near the boundary line. To what extent this depletion is serious has yet to be proved. By a careful comparison of the large number of well records in the field, the Committee of 1908 found that there was a great variation in the radius from which a well might draw its supplies of oil. Wells separated by less than 100 feet sometimes appear to be quite independent of one another. In other cases a new well put down several hundred feet from an old producer has been found to have a marked effect on the older well. The results of our local investigation coincide with conclusions from purely theoretical considerations: the sandbanks in which the crude oil is stored underground are not continuous sheets, but, as anyone might infer from the conditions under which sandbanks are formed, they are lenticular patches of sand separated by partial or complete envelopes of impervious clay; thus, two wells, separated by a short interval, may be tapping the edges of two adjacent, but distinct, sandbanks; on the other hand, one of these wells might be near the edge of the same sandbank as a third well several hundred feet away. In addition to this original disposition of the oil-bearing strata, adjoining wells may tap the same sandbank and yet be made independent of one another by a very slight fault of the kind extremely common in all oil-fields.

At great depths, where the oil is under pressure and is more mobile because of its higher temperature and larger content in the lighter hydrocarbons, there is probably a more complete communication between adjoining sandbanks than would be the case at shallower depths, where oil of the kind occurring in Burma suffers from the clogging effect of its high charge of paraffin; consequently, there is reason to suppose that, whatever may be the effect on Khodaung as the result of draining the Twingon Reserve, its effect will be proportionately more serious in the deeper than in the shallower oil-sands. Every oil-driller also recognises what he imagines to be channels of supplies underground; if he can get down his well to a producing sand before his neighbour reaches the same level, he thinks that it is possible to establish channels from the neighbouring parts of the sand towards his own well, and thus he concludes that he will have a permanent advantage over his neighbour. In this conclusion he is probably correct, and it is consequently likely that wells in the southern section of the Twingon Reserve will continue to rob oil from those put down by the Burma Oil Company to the same oil sandbanks in the Khodaung area.

It is doubtful if the summit of the great oil-storage dome, forming the rich part of the Yenangyaung field, lies on the Twingon or on the Khodaung side of the boundary between the native reserve and the Burma Oil Company's property. On the whole, there seems to be some slight balance of evidence in favour of the conclusion that the actual summit is within the Khodaung boundary. Thus, if it were a case of simple competition between one company working the Twingon and the Burma Oil Company working in Khodaung, the latter would have a slight advantage in the race. The competition has, however, been complicated by the circumstance that the Burma Oil Company are also the largest holders, by purchase from the *twinzas*, of sites in the Twingon area, and their policy has been, consequently, to drill at least one well as near as possible to every well put down by the competing companies. They know that the well-sites secured by other companies, though smaller in number, are so distributed throughout the reserve that their own interspersed sites would be largely drained if they did not take a share in the drilling competition. They are thus compelled to witness the drainage of their own property, and are forced to take themselves as large a share as possible in the process.*

* The vigorous action of the Burma Oil Company in the Twingon Reserve was naturally criticised by some of the witnesses examined by me as President of the Oil Committee in 1908. It should be remembered, however, that this Company entered the field before they could reckon on British protection, and it was through their enterprise that the value of the deeper oil-sands was first proved by drilling; they purchased distributed well-sites in the Twingon Reserve before any of the present competing companies were floated, and, on account of the threatened intrusion of a large foreign trust, paid prices at the time largely in excess of the

Those who are producing crude oil only for sale to refineries will regard the exhaustion of the Twingon Reserve as merely the end of their present easily-earned profits; and the capital to be recovered will be the small amount invested in the wells and their accessories. With some other companies, who have laid out large sums on refineries, the prospect is far more serious; for, unless other productive fields be discovered, and discovered at once, there appears to be a slender chance of the debenture-holder being able to realise the full value of his investment. The Burma Oil Company will be able to turn to its reserves in Khodaung (which is probably nearly as rich as Twingon), and to Singu, in

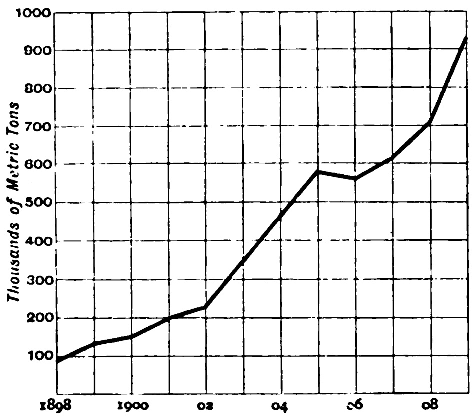

FIG. 6.—ANNUAL PRODUCTION OF CRUDE OIL, 1898–1909.

addition, perhaps, to a reasonable expectation of favourable results at Minbu, on the other side of the Irrawaddi river. I wish it were possible to show that the enterprise of all the other companies who have tied up their capital in expensive refineries had equally good prospects. But, as I have already explained, the existence of similar strata in other districts, and their disposal in structures suitable for the storage of oil, do not necessarily mean the occurrence of the crude material in commercial quantities. A wisely-governed oil company must necessarily keep in hand as a reserve large areas in which prospecting operations indicate good oil-supplies, and as no one can ever estimate the quantity obtainable, every serious outlay of capital must be regarded as speculative until profits are obtained sufficient to cover its amortization. All forms of mining must be accompanied by a considerable number of risks that cannot be accurately estimated, and while it may be necessary to secure a large nominal capital to be ready for possible developments, it seems to me to be an unwarrantable addition to, or rather a multiplication of, the usually great risks of oil-winning to lay out money on refinery plants for the visible output only from an already highly-drained field. In this case the exhaustion of the Twingon Reserve will be a serious loss to all companies, but it will mean absolute extinction to those that have no productive reserves in other districts. There is little doubt that the Twingon Reserve is now showing serious signs of fatigue; flowing wells, when struck, rapidly fall off, and most of the producing wells in the field are now reduced to pumping, with an average daily output of only about forty-five barrels.

The total production of crude oil in India has risen during the past ten years from $37\frac{3}{4}$ million gallons in 1900 to over $233\frac{1}{2}$ million gallons in 1909 (see Table V. and Fig. 6). Although the rise has been rapid and with but one small interruption, the output is still a small fraction, only 1·66 per cent. of the world's total production, which is nearly all due to foreign countries. In considering the question of using petroleum as a fuel, it should be remembered that only a fraction of the total crude output can be safely turned to account, and the total production of India in 1909, though expressed by a large figure in gallons, was not more than about 938,000 tons—that is, less than one-twelfth of the output of coal.

TABLE V.

TOTAL PRODUCTION OF PETROLEUM.

Year.	Quantity.		Value.
	Gallons.	Metric tons.	£
1900	37,729,211	*151,523*	148,755
1901	50,075,117	*201,105*	204,342
1902	56,607,688	*227,340*	217,816
1903	87,859,069	*352,848*	354,365
1904	118,491,382	*475,869*	473,971
1905	144,798,444	*581,520*	604,203
1906	140,553,122	*564,470*	574,238
1907	152,045,677	*610,625*	610,015
1908	176,646,320	*709,423*	702,009
1909	233,678,087	*938,466*	928,658

recognised market prices of well-sites, on which their drilling operations into the deeper oil-sands interfered in no way with the work of the *twinzas*, who worked the shallow sands only.

The indigenous product is insufficient to meet the country's requirements in kerosene and petrol, of which nearly 90 million gallons are still imported annually, to the value of about 2¼ millions sterling. On account of the high percentage of solid hydrocarbons in the Assam and Burma oil, there is a growing output and export trade in paraffin wax, which reached a value of £225,139 in 1909. The exports of kerosene are comparatively small, and are variable, as they merely meet the trade relations for exchange between the Indian companies and those of the Dutch East Indies supplying the Eastern market.

SALT.

Salt, apart from its market value, is among the important minerals, for, in addition to the half a million which it contributes to the annual total of production, it still yields a tax of over three millions sterling. The production of salt in India is, however, a Government monopoly, and thus calls for no comment from the mining investor's point of view. The annual production during the past ten years has been 1,174,329 tons, but there has been an increase in both production and import since the last reduction of the tax in 1907, although a portion of the increased consumption, now just 1¾ million tons per annum, is certainly due to the increased prosperity of the people. The tax has the merit of being shared by everyone, and now amounts to only 2½*d.* per head of the population, with an annual consumption of just 13 lbs.

Of the salt produced in India about 63 per cent. is obtained from sea-water, 26 per cent. is obtained from inland lakes and subsoil water in the dry regions of Rajputana and the Punjab, while the remainder, amounting to 11 per cent., is mined from the thick masses of rock-salt in the Punjab and North-West Frontier Province.

One of the most interesting features in connection with the industry is the discovery recently made by the Geological Survey that the enormous stores of salt accumulated in the desert region of Rajputana have been brought in in the form of fine dust by the hot winds which blow from the S.S.W. over the salt-incrusted arm of the sea in Cutch during the hot months of April to June.* The Government of India thus depend on the dry as well as the wet part of the annual monsoon for an important direct source of revenue. We have proved the existence in the superficial layers of silt under the Sambhar Lake alone of over 54,000,000 tons of accumulated salt, which has all been carried some 500 miles from the sea-coast, and there may be many Sambhars buried under the desert sands.

IRON.

There are two fairly prevalent ideas regarding India from the point of view of iron manufacture :—(1) That India is rich in iron ore ; and (2) that attempts to introduce European methods of smelting have failed in the past and are likely again to lead to failure. The failures referred to, although few in number, have been conspicuous and well advertised. Among them we have the concerns which developed from the initial efforts of Josiah Marshall Heath, who left the service of the East India Company in the early part of the last century in order to satisfy by commercial enterprise his belief in the rich mineral resources of Southern India. At a later date failure followed an attempt to smelt iron in Chota Nagpur, and again at Kaladunghi in Kumaun, where the ruins of furnaces and workshops stand as silent witnesses to misguided effort. Whether all these failures were due to conditions that still exist, or whether they were due, as has often been asserted, to mistakes that might have been avoided, cannot now be determined with certainty ; and any inquiry into their nature is not likely to lead to conclusions sufficiently certain and precise to be of present value. The only attempt to manufacture iron on European lines which has been successful still persists at Barakar, about 130 miles north-west of Calcutta, where success has been limited to the manufacture of pig-iron. For many years even in this area, where the natural conditions seemed to be so eminently favourable, the smelting of iron was unprofitable, and although the present Bengal Iron and Steel Company, since its management was taken over by Messrs. Martin and Company in 1889, has been a commercial success while confining itself to the manufacture of pig-iron, its experimental effort towards steel-making incurred a cost that soon led to its abandonment.

A new attempt is now being made to manufacture both pig-iron and steel on European lines by the Tata Iron and Steel Company, which was floated in August, 1907, with a capital of 1½ millions sterling. In so far as this company differs from all previous concerns in its constitution, in its policy, in the site selected for its works and in the ore-beds to be exploited, it avoids the specific causes of failure attributed to earlier enterprises. No member or friend of this new company will deny that its

* T. H. Holland and W. A. K. Christie : "The Origin of the Salt Deposits of Rajputana," *Records of the Geological Survey, India*, Vol. XXXVIII., pp. 154-186, 1909.

inauguration will involve a series of factors operating under previously untried conditions of natural resources, labour, management and market. Some of these uncertain factors can be estimated with fair precision, and for the others there appears to me to be provided a margin of safety sufficient to ensure success. The works will probably be ready to commence operations towards the close of the present year, and the progress which has been made towards construction and towards development of the ore, flux and fuel adds credit to the great reputation of Messrs. Tata, Sons and Company, who initiated the enterprise, and are now the managing agents and principal shareholders in the new company.

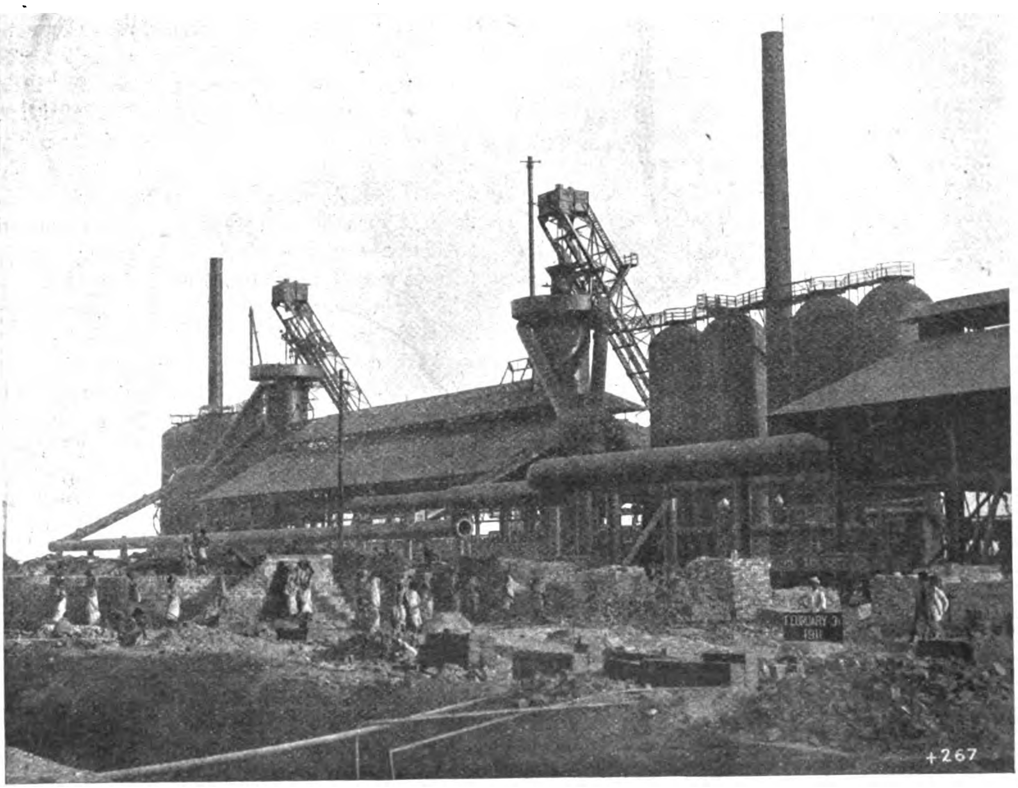

FIG. 7.—TATA IRON AND STEEL WORKS.
Progress in construction of blast-furnaces on February 3rd, 1911.

The new company propose to exploit the hematite ore-bodies of the Mourbhanj State in Orissa, where they have in sight all that they are likely to require for many years to come of an ore containing on an average over 62 per cent. of iron, with a content in phosphorus that is low, but nevertheless sufficiently serious to require preparation for the basic process in steel manufacture. The same company hold mining rights for a larger and a richer body of hematite in the Drug district of the Central Provinces, but it is doubtful if this reserve will ever be required to serve the new works. For coal and coke the company will rely on the resources of newly-acquired collieries on the Jherria field, and for flux on deposits of dolomite and limestone in Chota Nagpur, as well as on the well-known limestone of the Katni area. They have secured a site near the Kalimati railway station, 153 miles west of Calcutta, on the main line of the Bengal-Nagpur Railway, where they have abundant room for accommodating the new colony of workers on a healthy site, with an abundant water-supply for the workers and the rest of the community. The new works will be within 45 miles of the principal ore-supplies, and 130 miles from the collieries. With these advantages in the cost of assembling raw

materials of high quality, there should be no difficulty in competing with imported steel and iron of certain kinds and sections at Calcutta, which is the principal market for finished products.

The general idea that India is rich in iron ore is due to the fact that the smelting of iron was a widespread industry throughout the country for many generations before the British occupation. In addition to the smelting of wrought iron by a direct process in small "bloomeries," the natives of India formerly made steel of excellent quality, which had acquired a wide reputation even when Alexander the Great invaded India. The native smelting industry persisted in most parts of the country until the importation and distribution of cheaper European iron and steel became possible by the opening of the Suez Canal and the spread of railways throughout the country. After the European products obtained access to the country, the native smelter found it impossible to live, except in places far from the lines of railway, and thus the old-fashioned furnaces may be found still at work in remote parts of Madras, Chota Nagpur, Orissa, and the Central Provinces.

The simple requirements of the small native "bloomeries" are satisfied with deposits which, to the modern ironmaster, would not be worth consideration; consequently, the widespread industry of smelting does not necessarily mean the presence of ores in large quantities. A common source of ore is the formation which includes quartz-hematite and quartz-magnetite schists of the kind found in the Huronian and other pre-Cambrian systems of many parts of the world. These rocks are widely distributed throughout the crystalline areas of India; and although small "bloomeries" can be served by crushing and concentrating the friable fragments of these rocks, many of the occurrences cannot be regarded at present as sources of ore of commercial importance.

In many places the quartz-iron-ore schists form thick and persistent bands of great dimensions, including a total quantity of ore that might be considered serious if economical methods of concentration could be adopted; but it should be remembered that many of the old reports referring to these deposits as "inexhaustible" and "enormous" were based on the fact that the deposits were then out of all proportion in excess of any probable local consumption. It is quite possible that the formations of quartz-iron-ore schists in the Salem district, Madras Presidency, in the Mysore State, in the Nizam's Dominions, and some other parts of the crystalline areas in Peninsular India, are of a kind that might be considered large, but detailed estimates have never yet been made.

In considering the possibility of recent enterprise being successful, and of developing on a larger scale and at other localities, it must be remembered that, although the total requirements of India in iron and steel are large, the ports through which foreign steel arrives have the advantage of being within striking distance of the principal consuming areas, and the ports are not necessarily near the most suitable sites for smelting works. A large fraction also of the total value of imported iron and steel is made up of a greatly varied assemblage of shapes, sizes, and kinds of ordinary finished iron and steel, as well as of machinery, mill-work and plant, which have a value far in excess of the cost of the simple iron and steel employed in their manufacture. During the past five years the imports into India of iron and steel materials have risen in value from about 13 to over 22 millions sterling, but of this total only some 7 or 8 millions sterling can be regarded as iron and steel in a form that will be manufactured by new works in the country, and of this fraction a portion must be ruled out of consideration, on account of the fact that it pays only to manufacture a limited number of sections which are greatly in demand within reasonable distance of the works.

It is quite possible that in times of high prices iron ore of richness and quality equal to that being opened up by the Tata Company might be exported to Europe and America. Present rates of freight from Indian ports, added to railway transport from the interior, amount to a serious fraction of the comparatively low price of a ton of iron ore. But deposits like those of Mourbhanj, carrying well over 60 per cent. of iron, and forming solid masses which stand up as hills above the general level of the plain, permitting of the simplest and most inexpensive form of quarrying, might very well find an outlet to the European markets when rich ores are in demand. It is obvious that the exploitation of deposits of this nature involves no capital outlay, and consequently a very narrow margin of profit will be worth considering; while there will be no difficulty in turning out large quantities of ore on slight notice to meet any sudden demand, the exploitation being easily curtailed, or even completely stopped during dull times, without incurring any tax more serious than the dead-rent due to the State. Even this charge would

not affect a company which requires, for its own use, sufficient ore to cover the dead-rent; such a company could easily, when required, increase its output of ore at a moment's notice to meet any sudden demand in Europe, and could relinquish its additional source of revenue without keeping idle any large quantity of expensive plant. Practically the whole of the additional output could be met by unskilled labour in the case of the Tata Company, for the railway siding will be pushed into the foot of the hill of solid ore, and this company could even mitigate the disadvantages of varying demands for unskilled labour by accumulating heavy stocks of ore of determined and uniform quality ready for dispatch on a guaranteed assay.

Minerals Raised for Export.

Of the minerals raised only for export, I propose to refer briefly to gold, manganese, chromite, magnesite, mica, and saltpetre.

Gold.

Although gold usually generates more public interest than other minerals, it is of less importance in India than in many other countries. In addition to its direct value as a source of revenue, the discovery of gold is of value to most colonies as an incentive to immigration. India already possesses a population as great as it can conveniently feed, and as the successful mining of gold merely adds to the list of luxuries obtainable within the limited area in which it is worked, gold is of less importance to the country as a whole than those minerals which might, or already do, contribute to the general industrial development.

In small quantities gold has been found in various parts of the country, but the only successful mining on a considerable scale that has occurred, has been until very recently limited to a small part of the Mysore State, where from 1887 to 1905 there was a gradual increase in production to a record annual value of £2,428,162. In the next following two years there was a slight decline, with a subsequent revival in 1908 and 1909, the output of the last-named year being valued at a little over two millions sterling. In 1903 gold production commenced at Hutti in the Nizam's Dominions, and the production in that area has gradually risen to an annual value of between £50,000 and £60,000. Smaller quantities have been obtained by mining during the past few years in the Dharwar district of the Bombay Presidency, where the reefs occur in rocks belonging to the same system as those which have proved to be auriferous in other parts of South India.

In addition to the small amounts obtained by native washers in various parts of the country, dredging operations for alluvial gold have been carried on during the past nine years in the upper reaches of the Irrawaddi River, the production for 1909 being valued at £32,730. It is possible that the companies operating in this area, and others who have been granted large dredging concessions over the river gravels of Upper Burma, may prove to be commercially successful when they recover from the effects of their early accidents and errors.

Manganese.

I have already referred briefly to the political bearing of the mining of manganese ore. It will be sufficient now merely to give a statistical sketch of the extraordinary development of this industry.

TABLE VI.

Production of Manganese Ore.

Year.	Total Production.
	Tons.
1900	139,265
1901	157,736
1902	144,325
1903	177,821
1904	150,190
1905	247,427
1906	571,495
1907	902,291
1908	674,315
1909	642,675

Although various occurrences were recorded for many years in the publications of the Geological Survey, no one apparently thought of working the mineral until 1891, when the deposits of the Vizianagram State, on the east coast, became opened up through the enterprise of Mr. H. G. Turner. For seven years this was the only district worked, the output rising year by year until it reached nearly 85,000 tons in 1899. When the still richer deposits of the Central Provinces became attacked, the total production in the next following three years rose to about 150,000 tons. In 1903 work

commenced also in the Jhabua State of Central India, and in 1905 the Bombay Presidency commenced to contribute to the total by the development of ore-bodies in the Panch Mahals; while operations commenced during the same year in the Mysore and Sandur States in Southern India.

The greatest production in any one year was reached in 1907, with a total of 902,291 tons. As the extraordinary rise in production between 1905 and 1907 was accompanied by, and mainly due to, an extraordinary rise in the price of manganese throughout the world, the total for values rose far more rapidly even than the total for quantities, and owners of manganese quarries amassed enormous profits; for the deposits worked were accessible to the simplest form of quarrying in solid ore-masses, and realisation of sales was limited only by transport facilities to the rail and to the coast. With the fall in prices in 1908, and general curtailment of activity in steel-smelting, many of the Indian producers were compelled to close operations, and all were forced to restrict their output.

For many years Russia, Spain, and Brazil were the principal producers of manganese, Russia always being by a long way the leader. India, between 1896 and 1899, began to compete with Spain and Brazil for the second place; and Spain having then dropped out of the competition, the race proceeded between India and Brazil until 1905, when India rapidly shot ahead. Its total production in 1905 was about one-quarter of a million, in 1906 over half a million, and in 1907 not much short of a million tons; thus, in the last-mentioned year it closely approached the record output of Russia. In the following year, when all countries were compelled to curtail their output of manganese, and the Russian mines in the Caucasus were

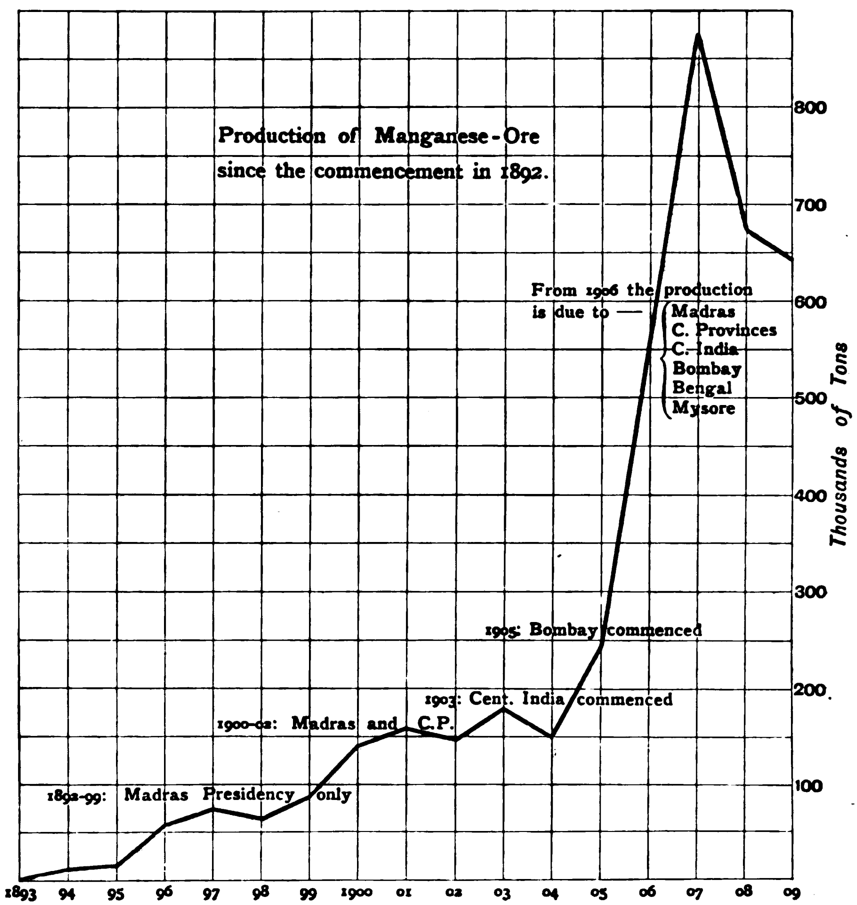

FIG. 8.

closed by political disturbances, India became for a year the leader.

Every question relating to the Indian manganese-ore deposits and their exploitation is discussed in detail by Dr. L. L. Fermor in an elaborate memoir recently issued by the Geological Survey.*

Chromite.

Although still worked on a comparatively small scale, the production of chromite for simple export is, like that of manganese, an industry which returns to the country at present a small compensation for the total loss of the mineral. Since the commencement of mining operations in Baluchistan during 1903, the output of chromite has amounted in that area to 26,697 tons; for this the Government has received in royalty and rents under £2,000, and would have received very much less, but for a local misapprehension of the rates for royalty laid down by the standing orders of the Government of India. The mining industry, which is of the simplest character, has maintained a small amount of labour in Baluchistan, but the total revenue received by the country is still but a small fraction of the market value of the mineral, which might be estimated at somewhere near £100,000. There is no doubt that the owners of the mines pay a tax that cannot be considered to be excessively lenient so long as the export of this mineral is permitted. The only question to be considered for Baluchistan, as well as for other parts of India where the mineral occurs, is the purely political one as to the desirability of depleting, without adequate compensation, our stores of a mineral which is likely to be of national importance for the manufacture of chrome-steel required for armour-plating.

The only other parts of the country in which chromite has been worked recently are the district of Singbhum in Bengal, and the Mysore State, the total production in these areas being so far under 20,000 tons.

Magnesite.

The olivine-rocks which have been worked in parts of South Peninsular India for chromite are generally also traversed by veins of magnesium carbonate or magnesite, formed by the alteration of the ferro-magnesian silicate, olivine. The most conspicuous occurrence, and the only one which has been worked to any extent, is that near the town of Salem, where the network of white magnesite-veins, covering low hills between the town of Salem and the Shevaroy Mountains, has given rise to the inappropriate name of the "Chalk Hills." For the last eight years the average production of the mineral in this area has been only 2,254 tons per annum, with yearly fluctuations so great as to indicate that the industry has not yet reached a state of steady production. The mineral produced is of unusual purity, and should consequently obtain a special value, but the only market for the calcined product is out of India.

The general criticism offered regarding the mining of manganese and chromite applies also to magnesite, of which the visible supplies are possibly below the probable future requirements for steel manufacture in India.

Mica.

Ever since mica has been a serious item of international trade, India has been by far the largest producer, the next two being Canada and the United States, while the output for other parts of the world forms but a small fraction of the total. Since 1894 the share of India in the total value of mica produced has varied from about 55 to 78 per cent., taking each year separately, or to a variation between 60 and 68 per cent. on consideration of quinquennial periods, as shown in the above table.

TABLE VII.

Average Annual Value of Mica Raised in the Three Principal Producing Countries.

Period.	Canada.	India.	United States.	Total.	India's per cent. of total.
	£	£	£	£	
1894-1898	14,598	*63,203*	15,030	*92,831*	*68·08*
1899-1903	32,110	*85,370*	24,477	*141,957*	*60·14*
1904-1908	57,070	*173,511*	50,260	*280,841*	*61·78*

* *Memoirs of the Geological Survey, India*, Vol. XXXVII., 1909.

Practically the whole of the mica produced in India is of the variety muscovite, which, on account of its hardness, elasticity, and freedom from foreign inclusions gives Indian mica a slight advantage in competition with the product from other countries.

The area which has been worked for the longest period, and is still the principal producer, covers the northern and western part of the Hazaribagh district, the eastern part of Gaya, and the south-western corner of Monghyr in Behar. Mica-mining in the next most productive area, namely, that of the Nellore district in Madras, dates from 1890, when a valuable mine was opened up through the enterprise of Mr. E. H. Sargent. Both areas owe their richness in mica to the same circumstance, namely, abundant intrusions of pegmatite veins among the schists, which, although belonging to the earliest of our great geological eras, have remained undisturbed by earth movements ever since. The slightest disturbance of the rocks would naturally result in the destruction of large proportions of a mineral so comparatively soft and delicate, for mica depends for its value largely on the flawless, uncrumpled condition of its cleavage sheets.

In Behar the mica-bearing country forms high ground which has been dissected out into scenic relief by the erosive action of the streams, and consequently in this area the mica deposits were first noticed and worked. In Nellore the mica-bearing country forms a flat and low-lying plain in which the rocks are largely masked by a mantle of decomposition products and cultivated soil, which effectually conceals the pegmatite veins. It is probable that there are still many valuable deposits of mica undetected in the Nellore district, in spite of the active prospecting which has followed the accidental discovery of a few valuable occurrences. In both areas the operations have been limited to depths that would be considered shallow in systematic mining. Although the primitive system followed, more conspicuously, perhaps, in Behar, has reached its productive limit in the case of many mines, a general reform in the methods of mining will be necessary for these two valuable areas to maintain their supremacy as mica producers.

Mica-mining in India must always remain in an uncertain condition until it becomes controlled by larger limited liability companies, who, with a larger capital and with smaller individual risks, will be able to adopt systematic mining operations to replace the present uncertain hand-to-mouth practice. The work so far done may be regarded as mere prospecting, and should form a valuable basis for planning operations on a scale sufficiently large to exploit the numerous deposits that still lie untouched.

Saltpetre.

Among the minerals exported, saltpetre is the only one that can be regarded as no permanent loss to the country, for it is produced by the action of so-called nitrifying bacteria under climatic conditions, especially in Behar, ideally suited for the transformation of decomposing, nitrogenous, organic matter into nitric acid, the necessary potash being so greatly in abundance that its loss will never be felt. There was a time when, on account of its position as the main source of saltpetre, India possessed special political importance, the occurrence of war or of a war-scare being sufficient to raise the price of the substance which was formerly essential in the manufacture of explosives. The discovery of other deposits of nitrates and the adoption of other compounds for the preparation of explosives, have reduced the value of saltpetre, whilst as an artificial manure it is being displaced by the potash deposits of Germany, by soda-nitre from South America, and by ammonium-sulphate recovered as a by-product in gas and coke making. The annual export from India has remained steadily for some years between 17,000 and 20,000 tons.

Possible Developments.

It would obviously be dangerous to attempt any detailed discussion of the mineral occurrences that appear to offer reasonable hope of exploitation. It is possible, however, in general terms to indicate certain occurrences that require more serious attention. Among these might be mentioned the alum-shales of the Punjab and North-West Frontier; the bauxite deposits, which are known to be rich in alumina in various parts of the Peninsula; barytes, which is in small demand for paint; various clays, including fire-clays, for the products of which there is a growing import bill now approaching £400,000 per annum; copper-sulphide ores, which in some cases may possibly be sufficiently rich in sulphur for the additional manufacture of sulphuric acid; gypsum, now raised to the extent of over 6,000 tons per annum in Rajputana for use merely as a white-wash; lead, zinc, and silver ores, known in small quantities in various parts of the country, and now being prospected on a considerable scale in Upper Burma; various rare earths, of which finds are reported from time to time,

including monazite occurring with the seashore sands of the Travancore coast; pitchblende, occasionally found with the mica-bearing pegmatites, and wolfram, occasionally found in considerable quantities with the tin deposits of Burma. With these might be considered also corundum and mineral waters.

Copper.

Among these substances, which in the usual words of the optimistic prospector offer "possibilities" of development, the most "promising" are perhaps the copper ores; they are widely distributed and have been considerably worked by a past generation, while the heavy and increasing demand for copper in India has recently attracted attention again to the question of developing the local ores. For some years past the copper imported into India has had an average annual value of about 1½ millions sterling, and the numerous projects in contemplation for the development of hydro-electric power promise an increased demand for the metal.

Copper ores are known to occur, and in the past have been considerably worked in the Nellore district of the Madras Presidency, in Rajputana, in Chota Nagpur, and at various places along the Lower Himalayas, from Kulu in the north-west to Sikkim and Bhutan in the east. In all these localities the ore is associated with rocks which resemble in geological relationships and lithological characters those known as the Lower Huronian of America. These rocks, consisting of various forms of schists and slates, are referred in India to a stratigraphical system distinguished by the name of Dharwar, the system of rocks in which the gold deposits are found in South India.

In continuation of the work initiated by the Geological Survey, operations are now in progress by the Cape Copper Company to test the probable value of the well-known copper-bearing belt which stretches for some eighty miles across the Singbhum district of Bengal. A locality which deserves further attention is Baragunda, near the Giridih coal-field. The thick ore-body opened up many years ago was not exploited, because the heavy fall in the price of copper discouraged the Company. Prospecting operations on a considerable scale are also in progress in the Darjeeling district and adjoining part of the Sikkim State, where unusual facilities for developing water-power will probably counterbalance difficulties of a local character in developing a mountainous country.

Bauxite.

Another mineral which deserves special mention is bauxite, of which large quantities have been identified in Bombay, the Central Provinces, Central India, and the Madras Presidency. Analyses of large samples in some of these cases have shown proportions of alumina well over 50 per cent., and they thus come into the class of bauxites which have been successfully worked elsewhere for the production of aluminium. Some of the concessions taken up for the purpose of working these deposits have fallen through because of foolish attempts to float companies for the purpose of manufacturing aluminium, instead of beginning in a more modest way with the extraction of pure alumina for export to existing smelting works abroad. There are one or two promising localities near which water-power might be cheaply turned into electricity; but it is evidently dangerous to incur a large capital outlay for the erection of smelting operations under unfamiliar conditions, while the manufacture of the pure oxide from the bauxite is a simple chemical process requiring small expenditure in power, and very little capital outlay in fixed plant. The low average price for raw bauxite at European ports would leave very little margin for profit after paying for the transport of the raw material from inland localities to the coast and thence to Europe; but as the purified oxide can be prepared economically on a small scale, and commands a price sufficiently high to make the cost of its transport comparatively unimportant, it is strange that none of the concession holders have so far commenced serious operations.

Corundum.

Among the smaller of the mineral industries, one that deserves more attention than it has received hitherto is the mining of corundum. For use as an abrasive substance corundum has been employed in India for many generations by the old *saikalgar* (armourer) and by the lapidary. The name is of Indian origin, and the original material used by Count de Bournon for his description of the mineral species came from South India. India is thus the home of corundum, and although the mineral has been raised for many generations in small quantities for use in the country, the known deposits have never been developed on any considerable scale for export. The demand for abrasive agents has increased during recent years, and has given rise to the production of artificial substitutes for emery and

corundum, such as carborundum, a compound of carbon and silicon made in the electric furnace, and alundum, or artificial corundum, now being manufactured from bauxite by the utilisation of cheap electric power at Niagara. Other natural and artificial substances of a lower grade of hardness are used to replace or to adulterate emery, such as crushed garnet and spinel.

In India corundum is widely distributed in various forms, and one of the occurrences, namely, that near Kangayam, in the Coimbatore district, resembles in geological features the deposits which have been worked recently on a considerable scale in the Renfrew district of Ontario. It is possible that in face of competition from natural and artificial abrasives in the countries of principal consumption, it would not pay at present to develop the Indian mineral for export to Europe and America. With, however, the growth of manufacturing industries in India, the mineral will probably receive greater attention.

Mineral Waters.

It is probably not out of place to draw attention to the importance of the numerous hot and mineral springs occurring in various parts of India. Their value, whether real or purely fanciful, is appreciated by the natives, and, in consequence of their unusual nature, they have become, in many cases, semi-sacred objects of reverence. It is possible that mineral waters depend much for their value on successful advertisement, but as there is a considerable importation into India of various bottled foreign waters, it may be worth the while of someone to make use of the local production.

Phosphates.

One of the most extraordinary features in connection with the trade of India is the large export of phosphatic manures in the form of bones. The exports during the past five years have grown to nearly 90,000 tons per annum, with a declared value of about £360,000. The loss of fish-manure and oil-cake can be made good by reproduction, but the phosphate of lime sent out in the form of bones has been derived from the soil, and, as India is singularly deficient in deposits of mineral phosphates, such a loss is serious for a country dependent almost solely on agriculture. When sulphuric acid is manufactured on a larger scale in India, and the chemical industries generally become thereby developed, it is probable that this loss of phosphate will be curtailed and the material turned to account in the country.

Alkalis.

Sodium carbonate and sodium sulphate, which were formerly among the chemical products recovered by primitive processes in India, are now neglected on account of the importation of cheap alkali. As, however, carbonate of soda, caustic soda, and bleaching powder are being imported in annually increasing quantities, it should be possible now or soon to manufacture soda with commercial success by a process such as the electrolytic process, in which the by-product chlorine can be turned at once into bleaching powder. Beside the demands of the extensive paper-mills, sodium salts are required for hide-curing and various other industries. With the cheap manufacture of alkali from salt it seems to be hopeless at present to expect commercial success for any attempt to collect the large quantities of carbonate and sulphate of soda, which occur diluted with the chloride in some of the lakes and subsoil waters of the dry regions. Reference has already been made to the decay of chemical and metallurgical industries in India, and to the fact that the demand for chemicals is growing in quantity and variety sufficient to maintain a family of products large enough to warrant commercial enterprise.

Political Considerations.

Some idea of the attitude of the Government to the mining industry may be obtained from the general rules prescribed for the grant of licences and leases. From the point of view of the miner and prospector they offer "concessions" on the whole more generous than those obtainable in our self-governing colonies. Whether the leases, which are based on these rules, sufficiently safeguard the interests of the country as a whole is a matter that will require review after some further years of development. It is possibly true that in the past our administrators have had a too nervous regard for the possible political complications which might follow any considerable influx of the class of people who seem to be constant accessories of every mining "boom," for such people are not likely to add to the general happiness of the community. But artificial interference with the natural causes of migration is always dangerous, and it is now recognised that the mining industries have more than once been local safeguards in time of famine; their development, at any rate, will modify that character of simplicity which, as I have said before, is a dangerous state of unstable equilibrium in the economic configuration of a large and over-populated country.

No administrator responsible for the progress of a country should risk the danger of burying the country's talents in the earth merely because their development adds to the responsibilities and worries of the district magistrate.

In addition, however, to the immediate interests of the mining community and the question of revenue, there is the greater question of India's future industrial development to consider when discussing our policy regarding mineral concessions. We should have before us always the two great considerations—(1) that minerals are absolutely vital to the industrial progress of any community, and (2) that, unlike the products of the field and forest, they can be used only once in the history of a country. The products of agriculture are capable of an unlimited reproduction, and the effects of bad farming form losses that are recoverable; but there are no artificial means for reviving a damaged mineral deposit; there are no fertilisers for exhausted mines. It should be remembered that exhaustion of a mineral deposit does not mean merely the removal of all minerals of potential value, but more often, unfortunately, it means the removal of the richest portion of the deposits that give the quickest returns to the capitalist, attended by the destruction for ever, from an economic point of view, of those deposits which are poorer but could be turned to account under certain conditions of industrial development. These are but economic platitudes, but, unfortunately, often forgotten in the cry for rapid development. The export of every ounce of raw material is a permanent and serious loss to the country, but obviously it is better to raise and export, even at a low rate, the certain surplus of our mineral products rather than allow it to remain of use to nobody.

It should be remembered that the conservation of the mineral products is in India not merely a provincial question; the future of the country as a whole is dependent on its minerals; the small amount of revenue obtained locally is unimportant in comparison with the great political question of economic independence, and the mineral policy, not only of Provincial Governments, but of the Native States, whose prosperity depends upon the stability of the Imperial Government, should be controlled with the greatest care. I would more readily grant the power of life and death to an administration than freedom in disposing of its minerals. The time is coming when the mineral question will be to India, in its geographically isolated position, one of the greatest of its political questions. We have there an enormous population rapidly learning the arts and luxuries of civilisation, and there is not one among those that are the luxuries of this, and the necessities of the next generation that are not dependent on its inorganic products.

There is no colony that has an external trade comparable to that of India, and no dominion of colonies that closely competes with it in this respect; but it should be remembered that its trade is still in the highly impressionable condition characteristic of a system in the early stages of its evolution. The traits that characterise the primitive system of barter are still prominent in India's external trade, which is largely a simple exchange of the natural products of a tropical climate for the manufactured goods of the more highly developed communities in the temperate zone. The opening up of other tropical regions will necessarily strike at the commercial prospects of India, while some of the products formerly obtained in abundance, through the rapid reproductive powers of a tropical climate, are now being manufactured more cheaply through the development of chemical science in Europe. India has soon to face these changing industrial conditions. The natural advantages of a rich tropical vegetation are now challenged, and in the new competition the Government must turn its minerals as well as its vegetable products to the best economical account. The country has lost nothing by the export of vegetable products that cannot again be reproduced; but to squander the mineral resources would be a crime to the country. Conservatism may be undesirable, but caution is essential.

Although beyond the immediate object of this paper, it is desirable to take this opportunity of removing, so far as false impressions can be removed, the well-advertised idea that the present so-called political unrest in India endangers the security of financial investments in mines as well as other industrial enterprises which involve expenditure on immovable plant. To me the form of unrest which has so far been manifested rather increases than otherwise the value of financial investments; for, among all results of our work in India, nothing has been so prominent in recent years as the general relaxation of discipline in the training of those who are about to take on the responsibilities of manhood. The recent schoolboy outrages will not be entirely regretted if they wake up our administrators, especially those at Westminster, to the importance of tempering a sympathetic rule

with healthy discipline, and the political stability of the country ought thus to be increased by this timely lesson.

DISCUSSION.

The CHAIRMAN said one or two little points had been suggested to him in connection with administrative matters. In his instructive and interesting paper the author mentioned that the Geological Survey Department, the commercial community, the mining industry, and the Government, were all practically at one as to the propriety of certain rules for mining licences and so on. He should like to give an illustration of how very great the change had been. At the time when Sir Thomas Holland went to India, he himself was in the Madras Board of Revenue, and that department was called upon to report on the mining rules, one of which was to the effect that after the expiry of the mining lease granted by Government, the surface was to be restored in precisely the same condition as it was when the licence was granted, no consideration being given to the fact that there might be some hundred thousands of tons of refuse on the top. That was now all changed. The author, by some astute method, had managed to accomplish what very few heads of departments had been able to do—he seemed to have obtained all the liberty he required for making his department as useful as possible. The intelligent office clerk, and possibly even some of the hierarchs, were sometimes prone to suggest financial or statistical statements for adding to annual reports, and that went on until the head of the department was very often overweighted with the writing of reports, and left very little time for doing anything else. He used to think in India that some officials regarded figures relating to facts as actually of more importance than the facts themselves. Lord Curzon made a most admirable attempt to get rid of that evil, and for a time was successful, but the disease was probably endemic, though it might be overcome in the course of time. The most extraordinary official statement he himself had ever had to sign was one that had to be sent to the Secretary of State some thirty years ago. The district he was in then covered about 8,000 square miles, and calculation was required as to the amount of carpentry work and masonry constructed during the year, and the notification was that it was to be put in pounds avoirdupois! He would not intervene further between Sir Thomas and the gentlemen with expert knowledge who were about to address the meeting.

Dr. WALTER SAISE said his interest in the subject of the paper was mainly with the coal question. Coal was not only the bulkiest and most valuable mineral product of India, but it was chiefly utilised on the spot for manufacturing and carrying purposes. But his interest was due chiefly to the fact that he spent thirty years in the coal industry in Bengal. When he went to India in 1878 the total output of that continent was 970,000 tons. Now it was nearly 12,000,000 tons, or thirteen times greater. He remembered at that time (in 1878) it was still a matter for discussion and argument as to whether Indian coal could be burnt on railways in the locomotives. He remembered seeing and reading a report made by a distinguished locomotive superintendent, in which it was stated that Bengal coal was not good enough for locomotive purposes, and that English coal must be used if speed was to be maintained on the railways. Nowadays Indian coal practically was the only fuel used on Indian railways, and speeds on Indian railways were quite good. The Bombay-Calcutta postal express covered the distance from Bombay to Calcutta in less time (about 8 hours less) than the P. and O. express from Calais to Brindisi, the distance being much the same. And that was done with Bengal coal. The use of Indian coal on Indian railways, to which the birth and growth of the Indian coal industry were mainly due,* was largely the result of the acquisition in 1870 by the East Indian Railway Company of its own collieries, against the wish of, and in opposition to, the then Government. For some years that colliery (Kurhurbaree Collieries) raised one-third of the total output of coal in India, and when the coal trade increased, by reason of demands for other railways, this colliery raised one-fifth of the output of India for some years. The East Indian Railway Company might be said to have educated Indian railways to the use of Indian coal. In 1890, when the output of coal for Bengal was 1,626,000 tons, the East Indian Railway Company made a further great step. That company deputed an officer to explore and map a coal-field of 180 square miles area—the Jherria Coal-field—published a map, and distributed copies to the landowners and merchants of Calcutta, and then built a railway into the coal-field. The Government of India had no part in this policy except a rather reluctant acquiescence. The result was seen in the output of to-day. That coal-field, tapped by the energy and foresight—and to the ultimate considerable profit—of the East Indian Railway Company, now landed 7,000,000 tons per year as compared with nothing in 1890, and the total outturn of Bengal had increased from 1,626,000 tons in 1890 to 11,560,000 tons in 1908, to the great advantage of the railway that encouraged the trade. He had related this little fact—not generally known—of the policy of the East Indian Railway Company, because it indicated that enterprise of this kind by either wealthy corporations or Government was necessary in that vast country where cheap carriage was the main problem, as it was in the case of coal. A new coal-field, Bokaro, was to be opened out by the joint enterprise of the East Indian and Bengal-Nagpur Railways, and would probably give a new fillip to the coal industry. A new coal-field with coal to be got merely for the trouble, so to speak, of shovelling it into wagons

* The coal used on Indian railways is still one-third of the total output, and may be looked on as the backbone of the trade, as it is continuous, and fluctuates slightly.

offered great inducements—where there was only unskilled labour and a large quantity of it available—for colliery enterprise. The only capital necessary was to provide shovels and picks on the part of the colliery owner and to put the coal into wagons, which the railways then take away. The expansion of the coal industry had been accompanied by an improvement in the methods of mining and colliery equipment, as Sir Thomas Holland's slides showed, and the management and labour had both become more efficient. The difference between 1878 and 1908 from his own experience he could say was very marked, and all for the better.

Dr. JOHN W. EVANS congratulated the Society on obtaining a paper from Sir Thomas Holland, who had set forth the enormous strides that had taken place in the mineral industries of India in the quarter of a century during which the Government had the good fortune to possess Sir Thomas Holland's services. The progress in India in this respect during the last quarter of a century had been greater than had occurred in the British Isles in perhaps three-quarters of a century. Sir Thomas early made his reputation amongst the mercantile community of India. He remembered lunching with him at a wayside railway station in Mysore, where a number of planters were discussing the visit of Sir Thomas to the State, and speculating as to what would be the results on the development of its mineral industries, none of them suspecting that the slim youth sitting by them was the man to whom they were referring. With regard to the future of the mineral development of India, there was nothing more difficult than to prophesy. The lines which it would follow in the next quarter of a century would probably be very different from those which it had pursued during the past twenty-five years, for there was no department of industry which might be expected to show throughout the world greater changes. In the extraction of metals from ores electrolytic methods would gradually be substituted for smelting, and the centres of industry would be to a large extent determined not so much by the distribution of coal as by the distribution of water-power. Where no water-power was available, and coal had to be resorted to, it required very little perspicacity to see that in many cases it would pay better to convert the coal into power and use the power in electrolytic processes in the extraction of metals than to employ it in what would in the future be considered the present crude methods. Whatever happened, however, the mineral industry of India in the future, as now, would owe an enormous debt, which could never properly be estimated, to the hard work and the intelligence of the late Chief of the Geological Survey in India.

Mr. ALLAN GREENWELL said that the paper vividly presented the great mineral wealth of India, and the complex social and physical conditions which governed its production. About five years ago he had the pleasure of going over the principal coal-producing fields of India and was much struck by the primitive methods that were used in coal production; but in the last few years with increased production the methods and apparatus had become very much more up-to-date. Improvement was bound to occur as the fields developed and the process of extraction became more closely allied to that in vogue in this country. Undoubtedly the trend of mineral production in India, especially coal, would very largely depend on the appreciation the Government had of the necessity of a close knowledge of the peculiar local conditions, and that knowledge could be only obtained by those who resided in India, and were acquainted with all its necessities.

Mr. PERCY BRAMLEY said he spoke as a man born and bred in India, and therefore to all intents and purposes a native of that country. With regard to the question of sugar, it had always struck him as very extraordinary that in a country like India, where the population were very large consumers of sugar, the market should be held by foreign countries. The consumption of sugar amongst the native population was enormous, but until some process could be introduced which would produce the sugar they required there would be a difficulty in competing with foreign markets. The natives of India did not want refined sugar; they wanted a coarse sugar known as *cheeni* or *shukar*, and also a form of condensed molasses called *gul*. If produce such as that could be produced in India there was a great opening. The sugar-cane was indigenous to the country, and there was no reason why India should be dependent on foreign supplies. With regard to oil, there was an enormous demand throughout the country amongst the common people for ordinary paraffin, which, during the last twenty-five years, had superseded to a large extent the ordinary country oil. In all village fairs, and in even the smallest villages, paraffin of sorts could be obtained. The market apparently was held now by Americans, but if the oil-fields of Burma and Assam could supply the want there were immense fortunes awaiting those who could develop the market. One point to be remarked with regard to coal was the increasing scarcity of the ordinary fuel of the country. Wood used to be very much more available than it was now, and the question of the fuel supply in northern India was becoming acute. There was an immense opening for coal for domestic purposes. It would be necessary, however, to cheapen the coal, and in that connection cheap transport was necessary. With regard to the railways the author had shown a map of the Raniganj coal-fields, showing the radiating railway lines. It was rather a pity that the rivers were not shown on the same map. Parallel to the railways was one of the finest natural waterways in the world, the Ganges and its tributaries, and the development of the waterways seemed to him to promise the opening-up of great possibilities in the question of transport. With reference to the Pench coal-fields in Central India, how far they were workable by waterways he did not know, but

it might be possible to get on to the head-waters of the Narbada. As to mineral waters, there were vast possibilities in the Himalayas, but whether the natives of India would ever be got to appreciate the value of mineral waters was very doubtful. On the subject of the education of Indian students, the difficulty in extending a knowledge of technical subjects amongst the people of India seemed to arise from the fact that until technical education was given to the working-classes who carry out the work the spread of knowledge would be retarded, because the class of student who came to Europe was not drawn from the working-classes. Any scheme of technical education devised for the people of India should be extended to the working-classes.

Sir James Wilson, K.C.S.I., in proposing a hearty vote of thanks to the author for a most interesting paper, said he had had the privilege of working with Sir Thomas Holland for a year or two when Secretary to the Government of India. The Geological Department was for a time one of the Departments with which he had to deal, and he had every opportunity of seeing the excellent work Sir Thomas Holland was doing in India. As Director of the Geological Survey, Sir Thomas added to our knowledge of the geology of India, not only from a practical point of view but from the scientific side, and he had watched his work as a scientific authority with great admiration. But Sir Thomas was not a mere scientific man; he could make a distinction between a geological theory and a practical business proposition, and his advice as to how the Government should deal with the people interested in the mineral development of India was always of a very practical nature, and was received, not only by the Government but by those interested, as sound and sensible. With regard to the attitude of the Government towards the mineral development of India, very often the Indian Government had been abused by impatient mining speculators and investors at home, who wanted to make money as quickly as possible. But the Government of India had other things to think of. Often there were questions of the ownership of the minerals below the surface, and the Government did not wish to encourage the mere company promoter, but desired to see that the people who were beginning to develop the minerals of India should do so in a reasonably practical way. Also it had to think of the interests of the people in the locality who generally owned the surface of the soil, and there were many difficulties which arose when a mining population came amongst a pastoral people and often ruined their character and their health. Naturally, therefore, there was occasionally some delay before a mining prospector obtained the lease he wanted. Sometimes there was a little red-tape and unnecessary delay, but on the whole the Government had shown itself ready to inquire into any grievances or complaints, and did its best to remove them in consultation with the people interested.

Mr. Abdullah Yusuf-Ali, I.C.S., in seconding the motion, said Sir Thomas Holland had dealt with a most difficult subject with the depth of an expert, the ease of an orator, and the humour of a man of the world.

The resolution was carried unanimously.

Sir Thomas Holland, in reply, said he was especially pleased to meet his old friend, Sir James Wilson, because it was under him as chief that the first review of the mineral production of India was prepared, and it was through his encouragement that the work was undertaken and carried out. He agreed with a great deal of what Mr. Percy Bramley had said, especially about the food supply in the United Provinces. It was all very well to issue Government orders to increase the amount of forests, but the amount of forests in India could not be increased without curtailing the cultivated land, and as there were more mouths to fill in India it was dangerous to reduce the cultivated land in order to increase the forests. He pointed out that the rapid development of the past few years was in no way the outcome of his work, but a merely fortuitous coincidence with his period of service. Much of the progress, however, was due to the foundation of systematic survey work accomplished by his predecessors and senior colleagues, all of whom, with himself, had worked in harmony with the mining community. He agreed with Mr. Percy Bramley in calling attention to the value of the great navigable waterways, but pointed out that the Narbada River could not be utilised as an outlet for the Pench valley coal. The river is separated from the Pench valley by the Satpura mountain range, while the river itself is not navigable. He recognised the value of Dr. Evans's suggestion that electrolytic smelting would in future change the form of metallurgical development; but it should be remembered that, on the peninsula of India, water-power can rarely be relied on as a continuous supply without expensive storage-reservoirs; the rivers vary so greatly in discharge from the monsoon to the dry season that many of the largest cannot be depended on for any serious supply of power throughout the year.

TWENTIETH ORDINARY MEETING.

Wednesday, May 10th, 1911; Mr. Edward Packard in the chair.

The following candidates were proposed for election as members of the Society:—

Côté, Thomas, International Waterways Commission (Canadian Section), Ottawa, Canada.

Fourie, Petrus Jacobus, Jansenville, Cape Colony, Union of South Africa.

Mott, Howard Schenck, 100, Broadway, New York City, U.S.A.

Piesse, Mrs. Adelaide E., Mountain Ash, Addlestone, Surrey.

The following candidates were balloted for and duly elected members of the Society :—

Boyd, Miss Emma S., 18, King's-road, Southsea, Hants.

Croll, George, Camden House, Chislehurst, Kent.

Holland, William W., Ph.D., Johns Hopkins University, Baltimore, Maryland, U.S.A.

Holman, Arthur, Ishapore, Bengal, India.

Howat, William Frederick, M.D., Hammond, Indiana, U.S.A.

Sanguinetti, Vivian, c/o Dr. H. H. Sanguinetti, 19, Camden House-road, Kensington, W.

Triggs, Bernard, c/o Messrs. Cox & Co., 16, Charing-Cross, S.W., and Royal Bombay Yacht Club, Bombay, India.

Wood, Casey A., D.C.L., M.D., Suite 1208, Chicago Savings Bank Building, State and Madison-streets, Chicago, Illinois, U.S.A.

The Chairman expressed the regret felt that the Earl of Denbigh had been unable to be present to preside, as his lordship had hoped.

The paper read was—

BEET-SUGAR FACTORIES.

By Hal Williams, M.I.Mech.E., M.I.E.E., etc.

I do not propose to-night to enter into a discussion, except very briefly, as to whether it will or will not pay to grow sugar-beet in this country, and establish sugar factories, because that, though the primary question, is the commercial one and outside the scope of this paper. It is a question, moreover, that cannot be decided without a survey of the international sugar market and the fiscal policies of the various sugar-producing countries. There is a popular idea that the sugar-beet requires an abnormal amount of sun, but this is incorrect, for what the root really does require is plenty of moisture up to, say, the middle of August, when the root is growing, and plenty of sun during September and the beginning of October. The climate of these islands may leave much to be desired from many points of view, but it does give the sugar-beet what it requires, and is admirably suited to its cultivation; in fact, experience has proved that better beet can be grown in England than practically anywhere else in Europe. The cultivation of sugar-beet on the Continent, where the climate is not so suitable, pays, and pays very well; and to any-one who has been through several sugar seasons there, and has seen the enormous extent of the industry, it is very remarkable indeed that an industry which is the life and soul, agriculturally speaking, of the north of France and Belgium, —to mention only one small sugar-producing area—can, with an even more suitable soil and climate in this country, less than one hundred miles further west, be without any commercial value at all. This state of affairs is the more remarkable and the more to be regretted, because while we in this country are suffering from very severe agricultural depression, and while large tracts of first-class soil are laid down in grass, which is the least intensive form of cultivation,

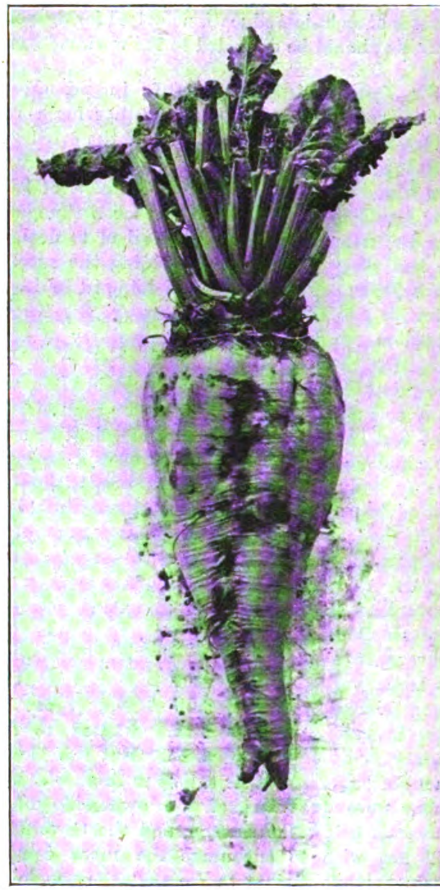

Fig. 1.

because it does not pay to grow anything else, there is hardly a piece of agricultural ground to be found in the Continental area I have just mentioned which does not bear a very profitable crop of sugar-beet at least every three years, and equally profitable cereal crops in the other two. In this connection also it is interesting to note that the cultivation of sugar-beet is increasing by leaps and bounds in the United States of America, where it is replacing the sugar-cane as a sugar-producer.

Beet gives the best results when grown with a two years' interval between successive crops, the best rotation being beet, wheat, oats. Fig. 1 is a photograph of a sugar-beet grown by Messrs. Sutton & Sons, Reading. You will observe that in appearance it is more like the common parsnip than any other root, and, like a parsnip, it requires a deep cultivation in order to get the best roots. It is for this reason, undoubtedly, that ground which has produced beet one year produces such excellent crops of cereals the other two. The roots are grown much more closely than, say, mangels, and the whole of the root should be covered with earth. For this reason they are more difficult to harvest than, say, mangel-wurzels, but any part of the root exposed to the sun and weather is valueless for sugar-making; in fact, even with roots which are completely buried, it is customary, before sending them to the sugar factory, to cut off a generous slice of the top of the roots with the leaves.

Fig. 2.

So much for the growing of the roots, which is, as I have said, a different department from that with which I have to deal to-night; to me the manufacture of the sugar with the huge possibilities it presents of introducing methods for saving time, labour, heat, power, and consequently cost, is by far the most interesting problem. I propose to describe the process in some detail, and if I can succeed in making myself clear in our imaginary journey through a beet-sugar factory, I am sure that you will be interested too.

Fig. 3.

I want to deal first of all with the way in which the roots are harvested and brought to the factory, and for this purpose I propose to show you some photographs which were taken

FIG. 4.

at a beet-sugar factory in the north of France last November, when the harvest, or "campaign" as it is called, was in full swing. Unfortunately, the weather was very wet, and as the sun had not its proverbial Continental brilliancy, the photographs are not as clear as

FIG. 5.

I should have wished. Fig. 2 is a very bad snapshot indeed of a beet field. I am disappointed that it should be so bad, because it was photographed in order to illustrate to you the small patches of beet which it pays the farmers to grow. The patch in question did not exceed some two acres, but it was harvested, and the beet carted to the factory all the same. Figs. 3 and 4 show the method of carting; the end of the sugar factory is shown on the left of the photograph. After the farmer has unloaded his roots, he takes the cart under the shoot (Fig. 5), from which the cossettes, or slices of beet after the sugar has been extracted, are delivered back to him. These are a by-product, used as cattle food, and are sent all over the country for this purpose. They are either mixed with about 4 per cent. of molasses, dried in ovens till they contain about 10 per cent. of water, and retained for winter food, or otherwise dealt

with. Fig. 6 is a view of the end of the factory, and shows the cossettes or slices being delivered into the railway trucks; while Fig. 7 shows trucks full of these spent slices, ready to be sent off to some more distant consignee. Fig. 8 gives a very good idea of the general appearance of the factory, and clearly shows the piles of beetroots which have been unloaded from either truck or cart waiting there to have their 15 or 16 per cent. of sugar extracted from them. Figs. 9, 10 and 11 are views of the same yard taken from the opposite direction. These photographs give a very good idea of the sea of beetroot waiting to be dealt with. To the right of Fig. 11 you will observe what looks like a ditch, with a man in the foreground cleaning it out. This is one of the "hydraulic canals," and there is one of these water channels under each pile of beet that you have seen. Water is let into each channel in turn, and the roots are conveyed by this water into the factory, being partly washed on the way. This is the beginning of the process. When the roots, after passing along the channel, arrive at the factory, they are caught in the wheel (Fig. 12), which lifts both the beet and the water into the beet-washer (Fig. 13). These washing machines are of various types, but in each the washing is done by the beets themselves, which are kept

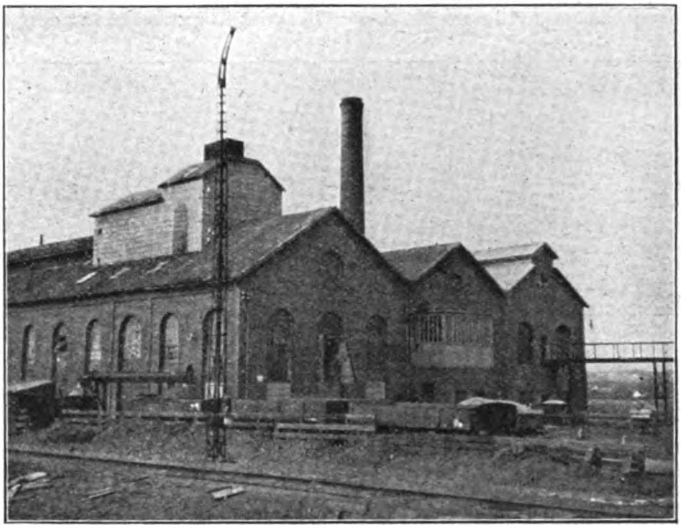

FIG. 6.

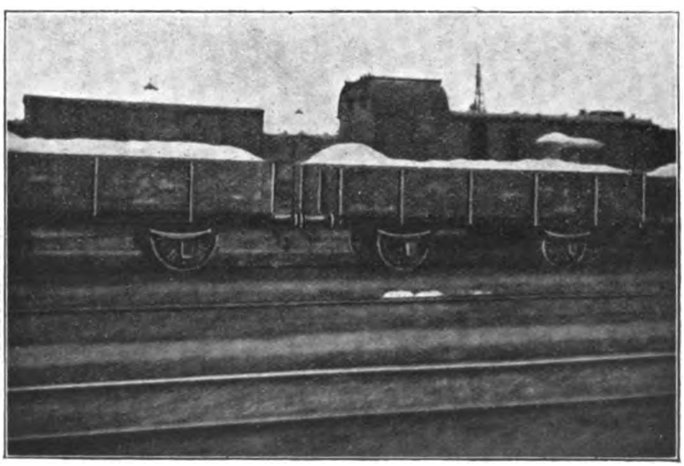

FIG. 7.

moving by the revolving arms shown, and which in consequence are cleaned by friction as they rub against each other. The cleaning is a very necessary and particular process, as small stones are very apt to get jammed in the roots, particularly if the ground in which they have grown has not been deeply ploughed, and the roots are bifurcated. These small stones play havoc with the cutting knives. From this washer the water returns to the channels to continue its work as a root conveyor, while the beet, after being weighed, passes up to the cutting machines, which, in order to get the full benefit of gravity, are frequently placed at the top of the building. These machines cut the beet into slices or cossettes of a corrugated or W section, the object of this shape of cut being to prevent the various slices lying so close together that the water which extracts the sugar cannot get to each surface.

FIG. 8.

as in Fig. 15. In either case the vessels are filled in turn with the freshly-cut slices. When the vessels are full, either fresh water, or water which has already passed through the adjoining diffuser, is let in, and the diffusers are worked in series in much the same manner as a battery of acidulating tanks until all the sugar in the slices, except about 0·2 per cent., which cannot be recovered, has been extracted. After diffusion, the water which has passed through the battery, and which contains the green or raw juice, is weighed and taken to heaters, and thence to the liming tanks, where it is treated with lime to remove the organic impurities. The cossettes, or exhausted slices, are removed by the elevator you see in Fig. 16, passed through the presses shown, which free them from the bulk of the water they contain, and are delivered into the carts or railway trucks, as we have seen in Fig. 5. An

FIG. 9.

After the beet has been cut, the slices are placed in the diffusers, which are arranged either in a circular battery, or in parallel rows. In the former case, considerable head-room is required, and the slices fall by gravity into the diffusers, as in Fig. 14. In the latter case the beet slices are conveyed to the diffusers by belt,

essential part of every sugar factory is the lime-kiln (Fig. 17), in which the lime-stone is calcined. This lime after burning is slacked to form milk of lime, which is mixed in carefully-measured proportions with the previously-heated green juice, which is then ready for the operation of the first carbonatation.

This process consists of treating the juice in special heated vessels with the CO_2 which was given off by the lime when burning in the lime-kiln, and which, after being caught and washed, is pumped into the juice. This CO_2 precipitates most of the lime as carbonate, and

FIG. 10.

the juice is partly purified. It then passes through filter presses as shown in Fig. 18, and is again subjected to the action of CO_2 in the second carbonatation, where it is further purified and again passed through filter presses. In some factories the juice is sent to the evaporators after this second carbonatation; in some it is first subjected to a third carbonatation and filtration. After the second or third

FIG. 11.

carbonatation, as the case may be, the juice is a light clear yellowish liquor at a density of 6 or 7 degrees Bé, and is ready for the evaporators. These liming tanks, heaters and carbonators are clearly shown in Fig. 19.

In the older factories the evaporators consist of the ordinary triple or quadruple effect pans with calandria, and are worked under vacuum, as shown in Fig. 19, but these are rapidly being replaced by the much more efficient Kestner Climbing Film Evaporator, working either with vacuum or pressure. One of these pressure evaporators is shown in Fig. 20; it evaporates 1,000 tons of water per twenty-four hours, which is the resultant from the 1,000 tons of beetroot dealt with in the factory. In other words, 1,000 tons of beetroot produce 1,250 tons of clear juice, from which 1,000 tons of water has to be evaporated. This is 80 per cent. evaporation, and in this particular case all the evaporation is being done under pressure with extremely efficient and satisfactory results. It would not be too much to say that Monsieur Paul Kestner has worked a revolution in the rapidity and economy with which evaporation takes place. In the ordinary type of evaporator the liquor to be evaporated has to remain in the vessel until the required density is reached. This is frequently a period of some hours, and the effect on the sugar juice

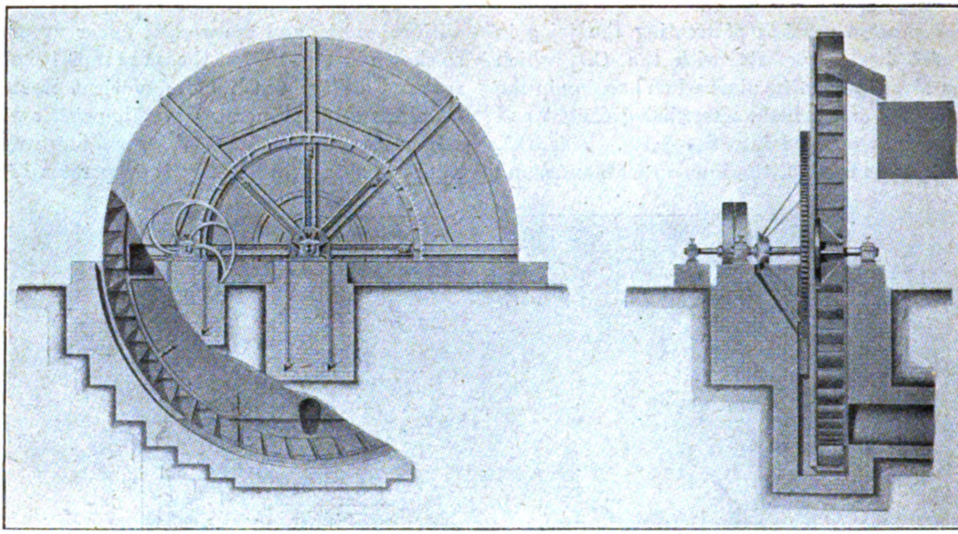

FIG. 12.

of so long an exposure to heat is deleterious. In the Kestner evaporator, on the other hand, it passes through in a continuous stream, remaining in the evaporator, and consequently in contact with the heated tubes, for a period of only about five minutes. After the juice has been evaporated to a density of 30° to 33° Bé in the Kestner, it is pumped into the boiling vacuum pans, which are of the ordinary type, where it is boiled—called technically boiling to grain—and evaporated until the malaxeurs, where it remains from four to ten days, and, when the sugar has sufficiently crystallised out, through centrifugal machines, which extract the second sugars. The molasses which remain are either sold to a distillery or are mixed with the dried cossettes and sold as cattle food. The treatment of both first and second sugars after evaporation will probably be considerably modified and simplified in future by a new process that is now being perfected by Monsieur Kestner. The present system is

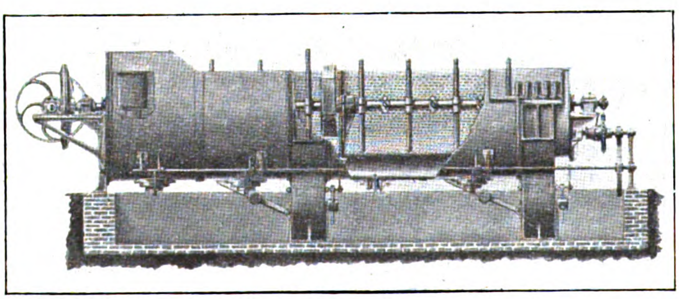

FIG. 13.

bulk of the sugar crystals have formed. It is then passed into cold malaxeurs, or stirrers, where it remains for from two to four days. These keep the mass of juice and crystals moving until the crystals have formed sufficiently, when it is passed into the centrifugal machines which separate the first crystals, known as the first product, from the remainder. The balance, consisting of mother liquor (*égout*) is sometimes and advantageously first treated with sulphurous acid, to render it less viscous, filtered, boiled to grain, passed through

an extremely lengthy and complicated matter, requiring very heavy and expensive plant.

The sugars of both the first and second product go to the refinery, usually a separate business, where they are dissolved in water to a solution of about 33° Bé, filtered through blackbone, and again boiled to grain. The wash liquors are evaporated, and the first, second, etc., products are turned into the many forms of white sugar which are so familiar to us.

This fleeting peep into the interior of a sugar factory, and the very brief summary of the

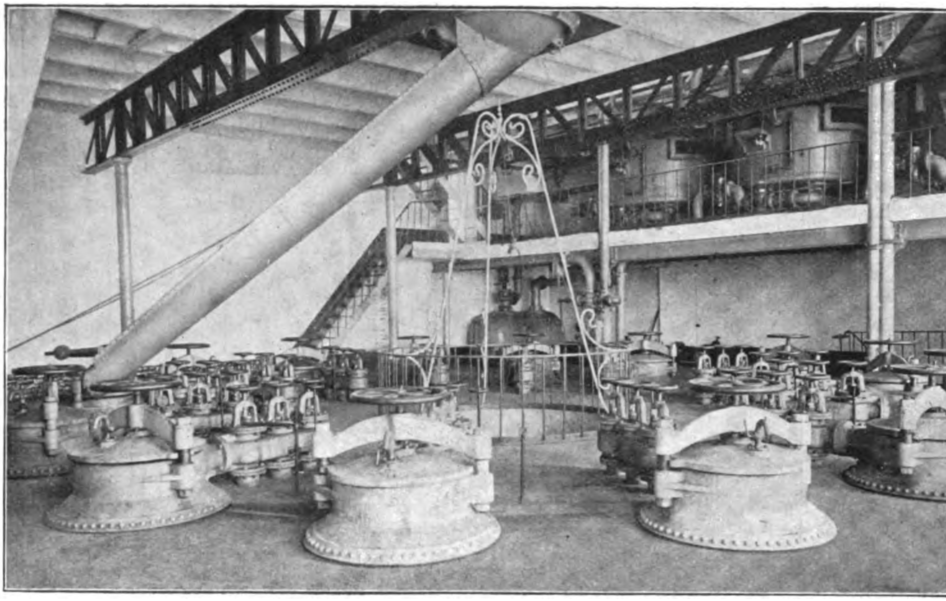

Fig. 14.

process of beet-sugar manufacture, will serve to show you that a sugar factory is not the simple place which so many people think it to be. It will also serve to give you some idea of the amount of money and thought which has to be expended upon its design, if the best and most economical results are to be obtained. The progress of the sugar from the time the beet first enters the factory till the time the bagged sugar leaves it, must be continuous and uninter-

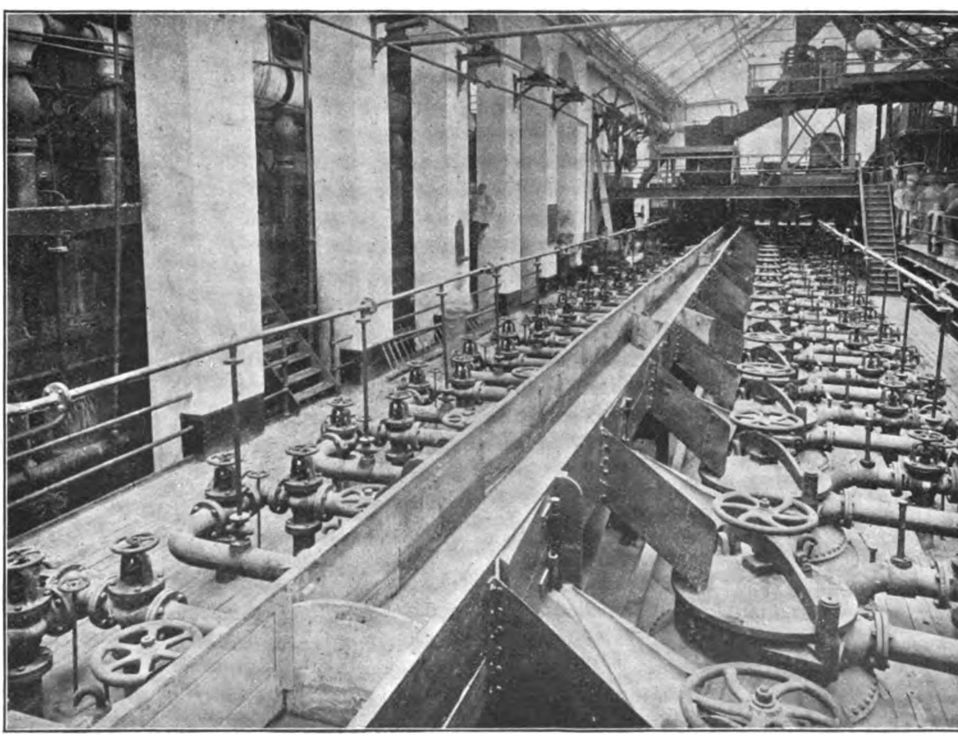

Fig. 15.

rupted; no ground must be covered twice, every available unit of heat must be utilised in suitable boilers and heaters, and every step forward must be as automatic as it is possible to make it. The molasses or waste material of the sugar factory is the raw material for several other industries, notably the distillation of alcohol, and the vinasse or waste of the distillery, or distillery wash as it is called in this country, is again the raw material for other industries. This vinasse contains the bulk of the nitrogen extracted from the soil, phosphoric acid, potash, soda and organic acids. It should really go back to the soil, but it is frequently used for making sulphate of ammonia and cyanide of potassium, so much used in gold-mining, and for killing blight in vineyards.

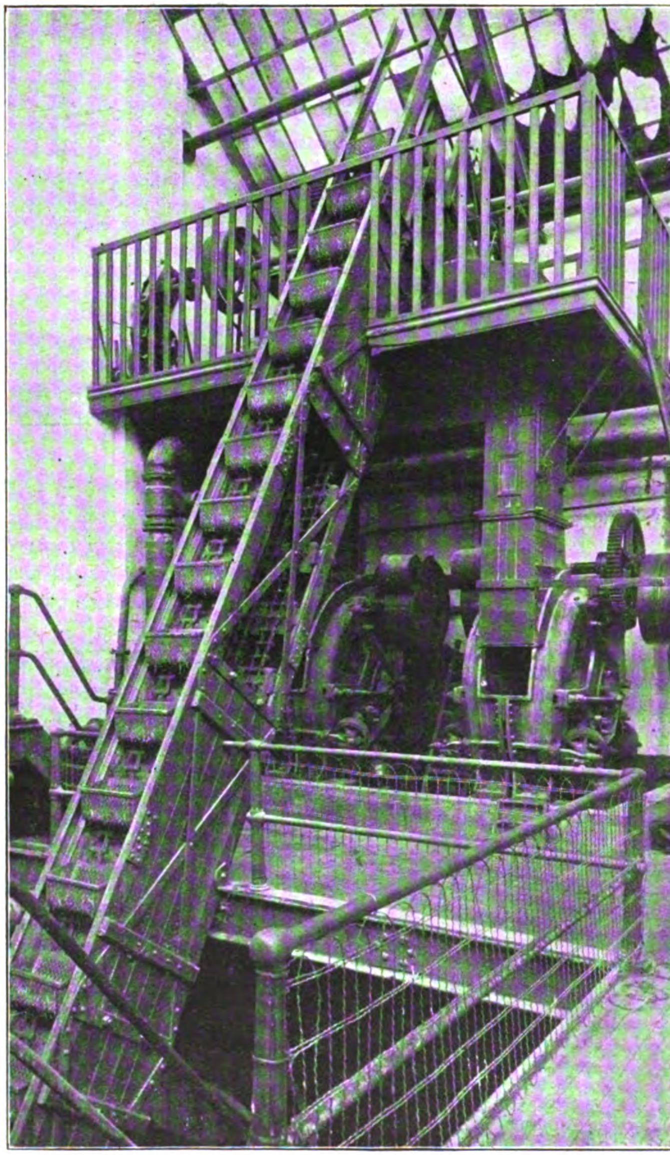

FIG. 16.

These different manufactories are all extremely prosperous, and if we consider the amount of capital on which they pay dividends and the amount they distribute in wages, we can reasonably ask ourselves—If for them why not for us? It is satisfactory to note, however, that at least some people in England are

alive to the importance of the question, and that the country is beginning to wake up. The admirable work done by the pioneers, particularly by Lord Denbigh, is likely to bear fruit in the near future.

The sugar factories abroad are of various sizes, the largest are owned by companies, many are owned by landowners who manufacture sugar from beet grown on their own property, while many are owned by farmers and run on the co-operative principle. A very good and usual size is a factory capable of dealing with 500 tons of beetroot per twenty-four hours, though there are many quite successful with a much smaller capacity, while many of the photographs which we have seen were taken in a factory capable of dealing with 1,000 tons per twenty-four hours. The process is, of course, continuous, and the "campaign" lasts about eighty days, after which time the factory is shut down for the rest of the year. A factory for dealing with 500 tons per twenty-four hours costs about £60,000, complete with buildings and plant. This factory would deal with 40,000 tons of roots per annum, which would represent the product under average conditions of, say, 2,500 to 3,000 acres, an amount of land which could easily be spared from grass growing.

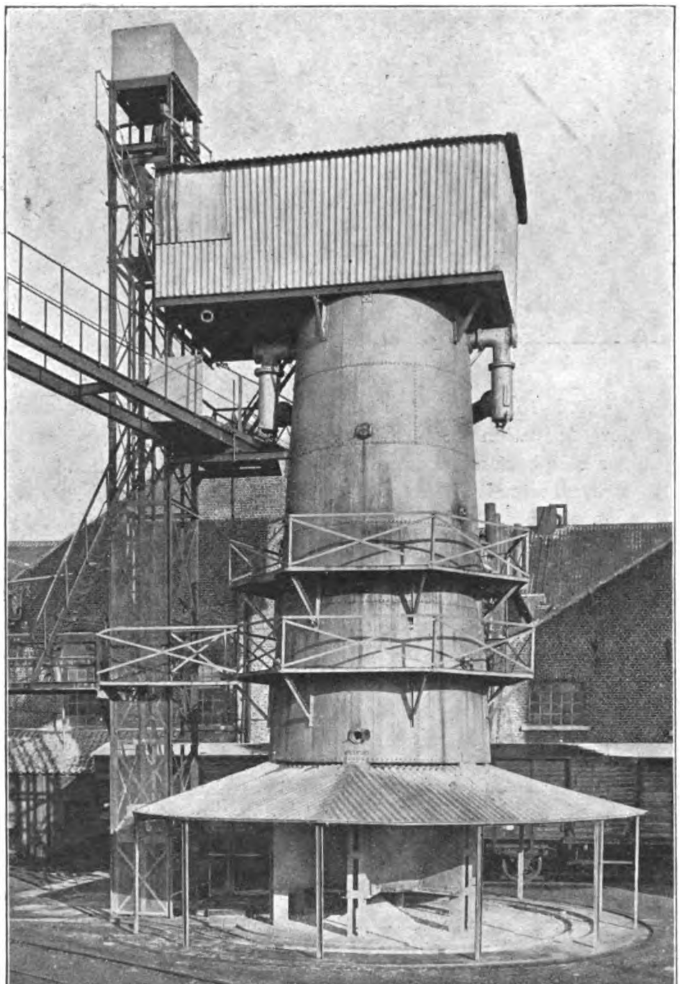

FIG. 17.

In England the beet might be expected to yield commercially about 17 per cent. of sugar, perhaps more. In France, where the soil is more exhausted, the average yield is 15 per cent., and in Germany 17 per cent., the larger yield in this latter case being possibly due to better seed, closer cultivation—notably manuring

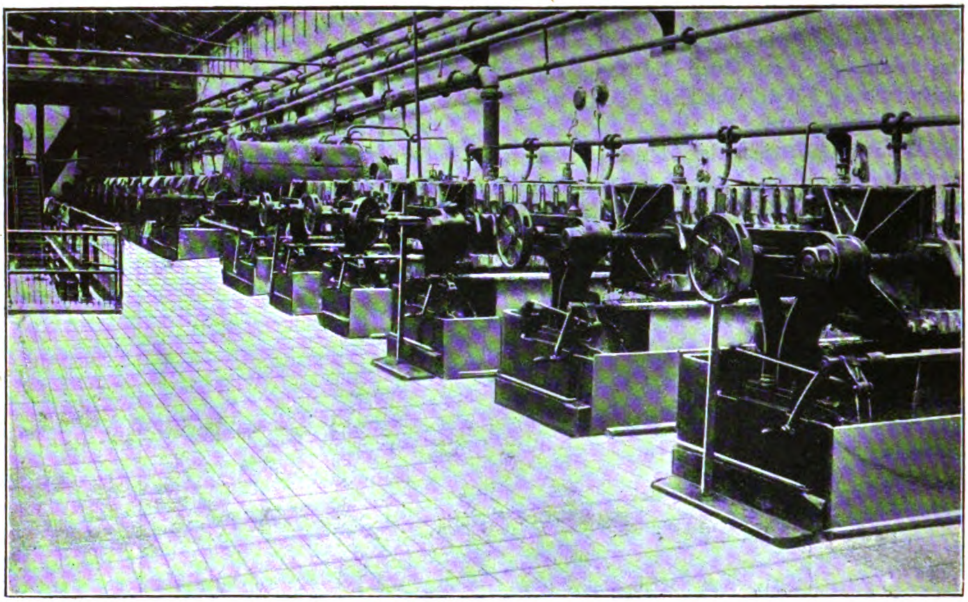

Fig. 18.

and deep ploughing—and to the fact that the larger area under cultivation enables the ground to get a longer rest between successive crops. There is, however, a great difference of opinion on these points. In France alone there were some 230 sugar factories, and only twenty refineries, this showing the importance of the industry and the relation between its two portions. In England we already have the refineries, why not the factories? During last autumn some 20,000 tons of sugar-beetroot were exported to Holland from England to be turned into sugar there.

I am merely a specialist in the building and equipment of factories, and am not a politician, an agriculturalist, or a fiscal expert; and it is, I suppose, because of my limitations in these latter directions that I am unable to understand

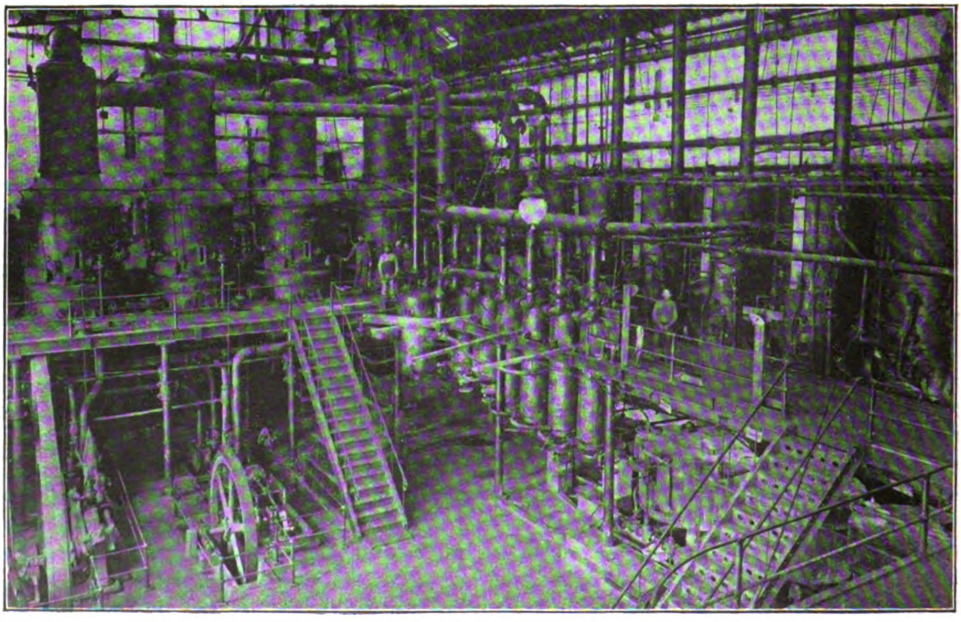

Fig. 19.

whether the inability of the inhabitants of the British Islands to produce and manufacture, at any rate, a large proportion of their own

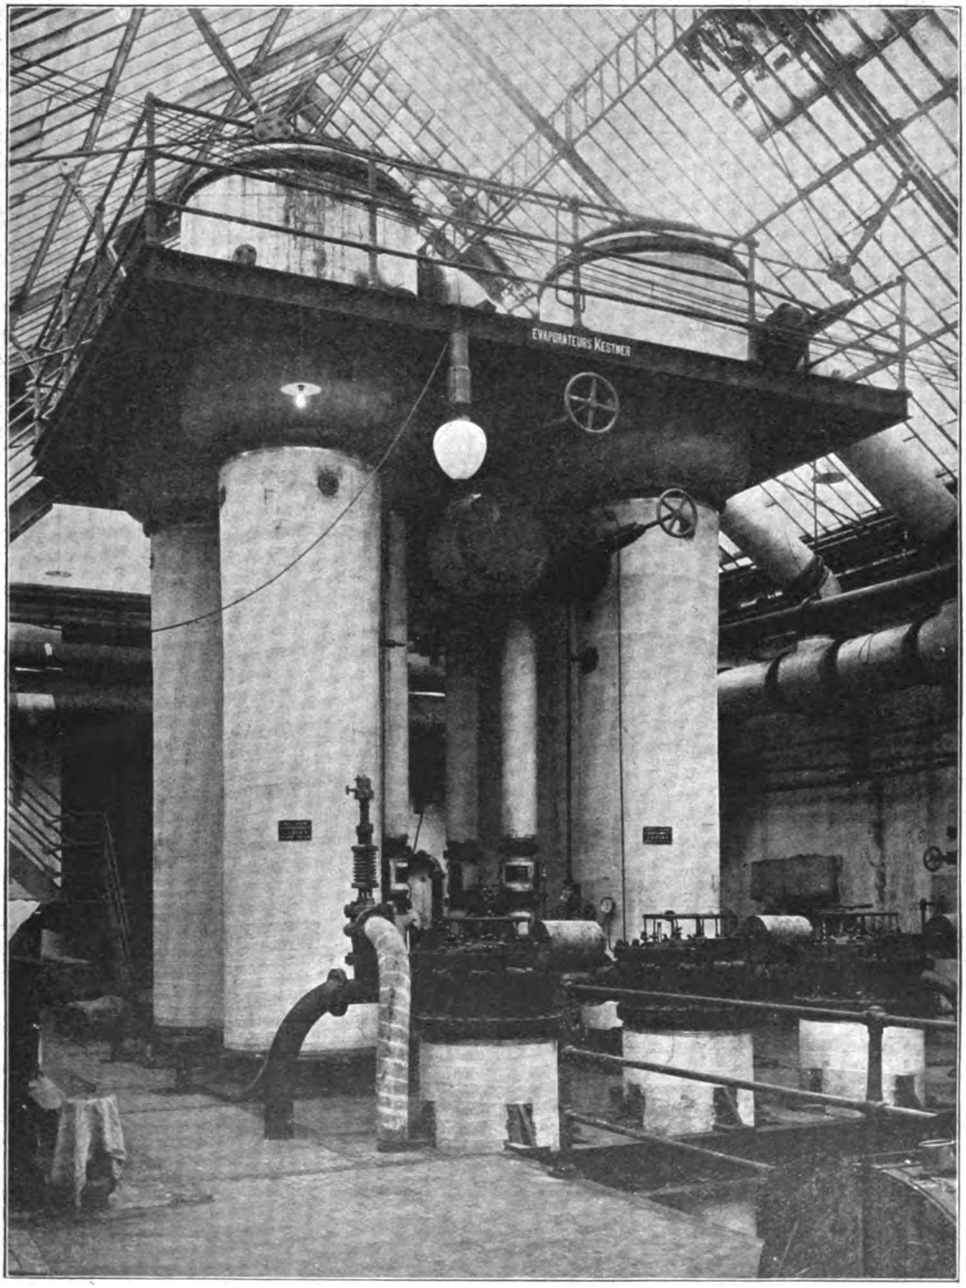

FIG. 20.

sugar, and to keep some of the many millions of pounds sterling which they annually send out of the country to pay for their sugar circulating amongst their own people, is really due to genuine and stable causes, or merely to apathy and ignorance. The proverb, "God helps those who help themselves," is as true to-day as when the expression first crystallised, and certainly our agricultural community does seem less fortunate in securing progress and prosperity than either their Continental neighbours

or their fellow-countrymen, who are working in other industries. Can apathy be the reason, I wonder?

It gives me pleasure to acknowledge my thanks to Messrs. Sutton & Sons, Reading; M. Gilain, Tirlemont; M. Alberic Dorzee Boussu, and M. Pellett, Lille, to whose kindness one or other of the photographs which you have seen are due.

DISCUSSION.

Mr. WALTER F. REID, F.I.C., said the subject did not deal with a branch of technology with which he was acquainted, but all who went often to the Continent must have noticed how great was the prosperity brought to certain agricultural regions by the cultivation of the sugar-beet. For such cultivation the land did not need to be very good, and the climate of Europe generally was not so good as that of England for the crop in question. Two years ago, in the autumn, when he was in Upper Silesia, the countryside seemed full of people; the explanation being that every available hand was anxiously looking after the beet, as there had been a frost the previous night. Every little while one came across a factory devoted to some agricultural industry, to make some material which English people imported, and which they might equally well grow themselves. This involved the important question of maintaining a large section of the people on the land. The extraction of the beetroot was now a matter of such accuracy, that the utmost could be got out of it; the experimental stage had long passed, and it only remained to adopt the latest devices. It would also mean the manufacture of a great deal of machinery for the purpose, and the accession of much traffic to the railways. In England there seemed to be much less corn grown than formerly, and much more land was given over to grass cultivation. The number of cattle, also, was diminishing, and that, too, in spite of the fact that we were importing milk from abroad. The demand for the beet industry was here. He asked how the masses of beet were protected from frost, which must act injuriously upon it. He concluded by reminding the meeting of an address to be delivered on the subject by the Earl of Denbigh at the Agricultural Hall on the afternoon of May 16th.

Dr. GUSTAF SCHACK-SOMMER said that England could certainly grow beet as well as any other country in the world. The question was whether it could be manufactured at a profit. The labour question was not a very large one, as the wages paid at the present day in Germany in the chemical industries were as high as in England. In Germany, the farmer who had once begun to grow beet never gave it up. Why should not that be the case in England also? The reason was that at present he had no inducement, and no tangible evidence that it would pay him. Why were not the rich people who were interested in sugar-refining coming forward and erecting factories for the beet industry? The reason was, that they were interested in buying the cheapest sugar. The farmer was the person who stood to benefit, and so any factories for that purpose should have farmers as shareholders. Mr. Rider Haggard found that the farmers in Denmark were interested in the sugar factories. In Germany and France the sugar factory was regarded by those nations as a Government agricultural school. The £60,000 mentioned by the lecturer for plant and buildings for treating 500 tons in twenty-four hours about coincided with what other authorities said; and that sum, if it was going to benefit the agricultural community so greatly, was not much to be found by the Government. Moreover, it would employ between 200 and 400 hands, a very important matter from the point of view of agriculture. He did not understand the remark of the lecturer that the Kestner appliance was without a vacuum installation; the Kestner appliance which he knew certainly had a pump. With regard to frosts, the beet grew beneath the ground, so that, until it was removed from the ground, it was not damaged by surface frost. And the "campaign" time did not exceed some sixty days.

Mr. G. L. COURTHOPE regretted the pictures shown by the author did not include some from Germany and Holland, as in those countries the industry was better organised than in France, especially the transport of the produce. So well organised was this latter, that seldom did the factories have more than twenty-four hours' supply on the spot at any one time. The question with regard to frosts seemed to have had reference to the beet when they were stacked. As the result of a calculation he made, the amount of beet-sugar imported into this country represented an expenditure of some ten million pounds sterling in wages for labour. And the extent to which beet was a cleaning crop was not sufficiently recognised; and one of the great advantages of beet was that it fitted in so well as a "rotation crop," and was much more profitable than swedes. He was informed on good authority that the sugar took nothing away from the soil at all, but, on the other hand, a lot of manurial product was put back in the land, so that the land gained from the crop. That fact explained why it was found on the Continent that where beet was produced, the yield of cereals in their due season had also increased, sometimes as much as 35 or 40 per cent. Why, in the face of those facts, had not the industry been established in England? First, because it must be done on a comparatively large scale to make it possible at all; there must be factories capable of dealing with as much as 500 tons in twenty-four hours, and 2,000 acres of land must be under cultivation each year for such factories, which was too large a quantity to get all at once. The £60,000 mentioned did not include the working

capital, and he did not think a start should be made on less than £100,000. Before investing his money, the capitalist wanted to be sure that the raw material was available to work on, and the farmer, before spending money on manures, wanted to be assured of a profitable market. Three attempts had been made in this country to introduce the beet-sugar industry, and in two of them there was failure because of avoidable mistakes. In one case, roots were contracted for, for delivery five months before the machines were in running order, and by the time the plant was ready the roots were not of much value. In another case—in Ireland—when a manager was wanted, a local publican was installed in that post. Another case was killed by the bounties which were levied in Germany in order to kill the industry in this country, which was showing great promise. But now that the bounty system was stopped in Europe, the fiscal future of the beet industry was simplified; it was possible for growers in this country to receive a moderate protection from the fiscal arrangements, limited to 2*s*. 6*d*. per cwt. in favour of the local producer as against the importer. We could compete in this country without that, though he would prefer we had the assistance of the 1*s*. 10*d*. per cwt. now in force. 20,000 tons of beets were exported to the Continent from the eastern counties this year, and it must be worth their while to do it, and for them to send the sugar back here as a manufactured article.

Mr. F. MacGregor Duncan called attention to the fact that eighteen months ago an attempt was seriously made to start the beet industry in this country, by establishing a syndicate—The Lincolnshire Beet-Sugar Company. Some gentlemen in Norfolk and Suffolk interested themselves in the matter, and when the time seemed ripe they took steps to construct a proper factory and grounds, and he (the speaker) was consulting engineer for the project. The syndicate obtained an excellent site near the Great Northern Railway, where there was water and other favouring circumstances. Visits were made to various German towns, and experts were asked to equip the factory with machinery which would yield a certain output. The public were appealed to for some £130,000. The contract for the building alone was £24,000, including much storage for dry beet. The contract for the machinery was £63,000, labour for erecting machinery £1,000, £2,000 for roads to factory, £3,000 for railway sidings, £2,400 for land, contingencies £6,000, working capital £18,000. The public responded by subscribing £50,000, which was returned to them. The firm who were to equip the factory worked night and day on the plans, as they felt the matter must succeed, and they were astounded at the result. The syndicate had entered into 264 contracts to grow beet with 264 farmers, whom it took two years to get to the point of entering into the matter. He agreed with what had been said as to the superior capacity of the Germans and Dutch to deal with the industry, as compared with the French. At the time the syndicate was trying to start the industry in England, people were tumbling over each other to invest in rubber shares. When the industry should be started, it was essential to get the co-operation of the farmers, and it should be for all time. In Germany, hosts of cottagers grew beet on their little plots of land, and at the due time carted it off to the beet factory. In England the first step should be, by means of lectures, to educate the people of the country on the matter, showing that there was an income practically waiting at their doors.

Mr. Arthur R. Ling congratulated the author on his paper, and said that in the autumn Mr. Matthews and he hoped to bring forward their work done on 150 samples of beet, which corroborated what the author had said as to the purity of the content of the English beet compared with that grown on the Continent.

Mr. Arthur Reavell, commenting on the question of the Kestner Evaporator, said Mr. Kestner was the first to find out the relation of heat and time together, and the effect of those factors on the sugar; he also found that in the process of evaporation one was able to keep the liquid in contact with the heating surface for only a minute or less, for a single effect; and for a quadruple effect, up to five or six minutes. The pressure-evaporators had a pressure of anything up to forty or sixty lbs. and instead of a vacuum, the vapour was taken away at a pressure of from one to ten lbs. The juice so treated was clearer and brighter, and produced better sugar than when treated under a vacuum. He was speaking of the concentration of the raw juice; the essence of the Kestner system was time.

The Chairman, in proposing a vote of thanks to Mr. Williams, said he was himself better acquainted with the manufacture of cane-sugar than with that of beet-sugar on the Continent. In 1885 he made his first experiments in growing sugar-beet in this country, and he proved in a few years that as good beet could be grown here as in Germany. Since then, seeds and methods had been improved, and so the yield per acre was increased. He believed in the British farmer, and his capacity to grow any produce against any farmer in the world. Still, it had not been proved that in this country we could convert the beets into sugar at a profit; yet it was most important, in the interests of both labour and agriculture, that the trial should be made. But at present the capitalist did not see his way to put down the money. The working farmer could not put down £60,000 for an experiment; it was often a difficulty for him even to make ends meet. He was not in favour of going to the Government for everything that was wanted; he believed in self-help. The matter was of national importance, and he did not see why it should not

be made to pay in this country. In regard to the efforts of the syndicate, he did not think the amount subscribed by the public was nearly as large as £50,000. By ventilating the question in that and other public ways, he hoped the attention of the public would be drawn to it, and that the assistance hoped for would be obtained.

Mr. WILLIAMS, replying on the discussion, said two questions—concerning frost and the Kestner evaporator—had been answered by other speakers. He did not show slides illustrating German factories, because his French was better than his German, and beet factories did not differ much in principle, though, like breweries, they differed in detail; it was chiefly a matter of personal idiosyncracy. He purposely did not depict the most up-to-date method of handling the beetroots before they entered the factory, as he wanted to bring out the point that if beet could be profitably handled with bullock-carts in the manner shown, it would be much more profitable under modern conditions. In some Continental factories some of the machinery was not modern, because the manufacturers could not afford to scrap their machinery when it became out of date and buy new. In England they would be starting *de novo*, with all that was best, most modern, and most economical. He contended that the figure he gave in the paper—£60,000—was right. But of course there was plant *and* plant, and there were buildings *and* buildings. He considered electric driving quite out of place in a sugar factory which was compact and where all exhaust steam was profitably employed. With regard to the response of the public to the attempt to float a company, it would have been wiser, before going to the amount of trouble which had been undertaken, to get the necessary capital underwritten. Possibly the public did not respond so much as the farmers, because they were not given the same inducement.

THE PEARL-FISHING INDUSTRY OF THE AMERICAS.

The richest pearl fisheries in the Americas at the present time are those of the Gulf of California, centering around La Paz, and along the outer coast of Lower California, in Mexico. These fisheries were discovered by Hernando Cortez when he marched across Mexico in 1526. The principal beds are near La Paz, in the Gulf, Espiritu Santo, Lorenzo Point, off the island of Cerrabro, Los Coyotes, and Mulege Bay, and, in fact, along the entire west coast of the Gulf from La Paz to above the island of Loreto and Tiburon on the east side. In addition to those found along the outside coast of Lower California, pearl oyster beds are also found at points along the southern coast of Mexico and Nicaragua, but, owing principally to the lack of protection for vessels, fishing has never been successfully carried on at these places. A few oyster beds have been found in the Gulf of Campeche, on the Atlantic side of Mexico, and a bed nearly ten miles long was located not long ago off Punta Santa Cristobal. These beds are now being worked under concession from the Mexican Government. Up to thirty years ago, *buzos de cabeza*, or head divers, only were employed on the La Paz beds, but on the revival of fisheries about this time, modern diving apparatus was introduced, and to-day they are being worked under concession by San Francisco firms, who employ from eight hundred to a thousand men. There are two classes of divers—those who go down head first and who use no weights to facilitate descent, and those who go down feet first. The pearl shells from these waters are not as large as those of Ceylon, but run from 6,000 to 7,000 to the ton. The true pearl oyster, the Meleagrina of the Indian and South Pacific oceans, varies in diameter from two to eight inches, according to age, six inches being the average. The greater part of the shell from the La Paz fisheries is shipped to San Francisco, while most of the pearls go to Mexico city and Paris. In 1908, the production of these fisheries was valued at £1,000,000, the pearls representing £600,000, and the mother-of-pearl shell the balance. The Lower California pearls are of a great variety of shapes and colour. Some very famous pearls of history have been taken from these waters. One of the most beautiful gems of the Spanish crown is an enormous Mexican pearl, found near Loreto by a native diver, and weighing 400 grains. Among the poorest natives of Mexico beautiful pearls are often to be found, usually mounted very crudely in rings, combs, earrings, chains, etc. The Gulf of Mexico was at one time famous for its production of the rare black pearl, and a number of these have recently been taken from the beds in the Gulf of Campeche. In Venezuela, according to a recent report by the International Bureau of the American Republics, the principal oyster beds are located around the island of Margarita, and at Cubagua, El Tirano, Gulf of Paria and Coro, Porlamar Maracapana, and Macanao, so that this part of Venezuela became known to the early Spaniards as the Pearl Coast. It is said that, in 1579, King Philip of Spain obtained from Margarita a magnificent pearl weighing 250 carats, and variously estimated as being worth from £6,000 to £20,000. The Venezuelan pearls are of very good colour, and these fisheries are specially famous for the number of beautiful baroques found. During the early days of the Spanish in the Caribbean, great numbers of fine pearls were found in the waters about the island of St. Thomas, and within late years Haiti and Santo Domingo have produced many delicate white pearls. It was in the Bay of Panama that the Indians first demonstrated to Balboa the manner in which they fished the pearl oyster. The principal fisheries of these coasts are among the Islas del Rey, or King's Island, now known as the Pearl Islands, lying in the Gulf of Panama about fifty miles from the city of Panama, and consisting of Rey Island, Pacheca, Pedro Gonzales, San Jose, and a number of smaller islands to the

north. Other important fisheries are found among the islands of Coiba, Coibita, Jicaron, Secas, and Contreras to the north-west, and off the south coast of Chiriqui and Veraguas. Rich beds have been found at times along the shores of the Golfo Dulce in Costa Rica, and around Punte Burica in Panama. Some beds are worked along both the Pacific and Atlantic coasts of Colombia, and on the Pacific side as far down as Ecuador and Peru, although not to any considerable extent, owing to unfavourable conditions prevailing, due to tide and unprotected coast-line. Of the Pearl Islands of Panama, Rey Island is the largest of the group. The only village of any size among these islands is San Miguel, as old as the fisheries themselves, the tower of its little masonry church being thickly inlaid with beautiful shells from the fishing grounds on all sides. At the present time there are about twenty diving machines and three hundred head divers at work on the Costa Rica, Panama, and Colombia pearl fisheries. The divers of these waters, as well as those of Mexico, suffer more from deafness than do the East Indians, the average depth of water in which they work being greater. The shell that comes to the market from the west coast of Central and South America is known as the Panama shell, and is usually of a bluish-black tint, The oysters average five to six inches in diameter, although some very fine pearls have been found in smaller ones running from four to five inches. In Colombia the concessions for the Atlantic fisheries, as well as those of the Pacific, are leased for a term of five years. The Costa Rica, Panama, and Colombia fisheries are famous for their black, green, and bluish-tinted pearls, although many beautiful delicate pinks have been found. In March, 1909, there was found, on the south coast of Chiriqui, a pearl weighing 42 carats, about the size and shape of a partridge egg, greenish black at the base, and becoming lighter towards the tapered end. The most beautiful pearls found on these coasts are rarely offered for sale in Panama, but are sent direct to Paris. From the United States and Canada come the fresh-water pearls, which are produced principally by the Unio, a species of mussel common to all the mountain streams throughout the country. In 1857, a pearl of exquisite lustre, weighing 93 grains, was found near Paterson, New York, which became known as the Queen Pearl, and which came into the possession of the Empress Eugenie of France. Pearls have been brought to the New York market from almost every State in the Union and Canada, principally from Ohio, Indiana, Illinois, Kentucky, Missouri, Arkansas, Michigan, Minnesota, Tennessee, and Mississippi. Garcilasso Inca de la Vega gives an interesting account of the manner in which the Indians of what is now Southern Georgia obtained their pearls, and their manner of using them. He states that the chief came to De Soto one day, bringing him a present of a string of pearls five feet in length, which were as large as filberts, and "had they not been bored by means of fire, which had discoloured them, would have been of immense value." He informed De Soto that these pearls had been gathered in the neighbourhood, and that in the sepulchres of his ancestors were amassed prodigious quantities of them, of which he was welcome to carry away as many as he pleased. In describing the manner in which the Indians strung their pearls, he says "the Indians were apt also further to injure the pearls obtained by boring them with a heated copper instrument." The conch shell found in the West Indies, along the Florida coast and among the Catalina and Santa Rosa islands of California, yields a pearl of beautiful pink, and often of symmetrical form, but, not being nacreous, cannot be considered a true pearl. With the opening of the Panama Canal, or even before, and the use of more modern diving machinery and systematic planting, such as is being successfully employed on the Mexican and Australian fisheries, the once famous pearl fisheries of the coasts of Costa Rica, Panama, and Colombia might again rank among the richest in the world.

THE PORT OF ANTWERP IN 1910.

The increasing commercial development of Belgium and the special activity of Antwerp lend considerable interest to Sir Cecil Hertslet's report on the shipping and navigation of that port for the year 1910. For the Port of London the prominent position that Antwerp is rapidly assuming, as one of the world's principal ports, possesses a peculiar significance. The shipping returns showed a very considerable increase of six per cent. over those of the previous year, thus again establishing a record for the port, and the new basins opened only four years ago proved on more than one occasion insufficient for the growing needs of the port, vessels being compelled to wait their turn before being able to take up their berth positions. In addition, labourers and employers are now in harmony, and the Consul-General is of opinion that there is no cloud to darken the horizon of commercial prosperity.

A point of some importance as affecting British prestige is that the Congo Mail line was in 1910 taken over by Belgium in fact as well as in name. Up to February 1st, 1911, this line had been entirely British as regards capital and working, though the vessels flew the Belgian flag under agreement, but since then the "Compagnie Belge Maritime du Congo" has been absorbed by a company, the representative capital of which is 60 per cent. Belgian, 20 per cent. British, and 20 per cent. German. Still British interests do predominate, and will doubtless continue to do so, though the rate of increase is not so great as before.

The desire in Belgium is very general to assist the national merchant marine, but the numerous attempts in that direction have never met with any great degree of success; the Belgian adapts himself to most conditions, but, generally speaking, he is not a good sailor and cannot compare with seamen

of other foreign nations such as the Scandinavian races.

The returns for 1910 show a larger number of vessels of a considerably greater tonnage than have ever before visited the port in one year. Moreover, there is every prospect of the figures for 1911 proving a record: freights are better, imports and exports are increasing, while, as a surest sign, there is a general aspect of contentedness, together with brisk movement in commercial quarters, giving evidence of the satisfactory state of markets and of business in general.

Vessels under the British flag still far exceed, both in number and tonnage, those of any other nation. Although it cannot now be said that the United Kingdom is accountable for more than 50 per cent. of shipping at Antwerp, as it was a few years ago, nevertheless the British figures are not far short of half of the entire port returns. And this reduction, be it observed, is accounted for by an unusual increase in Belgian tonnage and not by a decline of British shipping. In point of fact the latter shows a large increase over the record figures of 1907, both in number of vessels and aggregate tonnage.

Next in importance comes Germany, which claims close on one-third of the port's shipping, so far as tonnage is concerned. But while a large number of British vessels make Antwerp their final port, thus bringing much trade to the city, many German vessels merely call to embark a few passengers and discharge and load little cargo.

Both the city and port of Antwerp are being enlarged, the extension of the former having been rendered possible by the dismantling of the fortified *enceinte* surrounding the town and its re-erection on a convenient system far beyond the present site. As for the pool, elaborate arrangements are in progress and are to be carried out as circumstances require. Two transverse basins and a portion of the new canal dock are undergoing construction; the former are estimated to be finished in about two years from the present date.

ARTS AND CRAFTS.

The Building Exhibition.—The Building Trades' Exhibition at Olympia is always an event of some interest from the point of view of applied art. No one who is well acquainted with the scope of the show expects to find there the *dernier cri* in the way of decoration and design, or to see the latest productions of the best known manufacturers displayed in large quantities; what one does look for, is an opportunity of seeing just the point at which the ordinary average taste of the community has arrived. The type of wall-coverings, tiles, leaded lights, distemper and enamel colours, and so forth, for which the middle-class customer all over the country is for the moment prepared to ask, and which the local builder and decorator has to supply, is very thoroughly exhibited. This year the prevailing note in design was a certain soberness. Excesses of all kinds were singularly absent, and one gained the impression that people are at present content with either small and rather inoffensive patterns, or with those which they consider securely "traditional" in character—copied from, or designed after the manner of, some well-known style. One rather daring playing-card frieze was shown, and some of the large patterns on black backgrounds were a trifle startling, but the exhibits of wall-papers and of wall-coverings of various kinds were on the whole safe rather than interesting. Stamped steel does not at first sight appear to lend itself very well to interior decoration, but some of the steleonite ceilings, cornices, etc., of the Emdeca Company were quite good in design, and suggest that if they were painted in more suitable colours they might be very useful for certain kinds of decoration work. There was a large show of tiling of all sorts and kinds. Some of the glass tiles now made in matt vitreous paste are produced in very good colours, and have a decidedly pleasant surface. The colouring is, of course, from the nature of the material, dumb rather than bright in quality, but for all that it is, in its own way, quite attractive. A good proportion of the rubber tile and mosaic flooring, too, is sufficiently agreeable to look at, and the shaped pieces of rubber fit well and closely together and make a floor-covering which is not only apparently incapable of harbouring dust, but is also peculiarly fit for ships, bathrooms, and other well-marked uses. A few of the brighter colours are sometimes more than a trifle crude, but they are at least pure and clean looking. Clay tiles were, for the most part, shown as adjuncts to the exhibits of the various stove and grate-makers, and took therefore the form of surrounds. The Well Fire and Foundry Company had a special display of their "Welft" decorated tiles, which were interesting on account of their singularly untilelike colour. The oranges and purples were distinctly suggestive of pigments not used as a rule in pottery decoration, and the semi-matt surface of the tiles added to their unusual appearance. One could not but think, however, that those on glaze colours were hardly adapted for their place, and would probably look shabby in a very short time. The designs, mainly rather small in scale, seemed to be applied by some stencil process. The simple arrangements of some of the Medenham tile panels were tasteful in a rather artless way, and there were some good panels of tiling on the lines of the old Persian work which looked like the work of the Pilkington Tile Company. The painted landscape tiles so commonly met with in surrounds some years back were conspicuous by their absence, and the tendency as a rule appears to be to frame up very simple panels for use at the sides of grates, or to employ richly-coloured plain tiles, or even allover patterns with no framing at all. The French tiles and specimens of the special Delft wall decoration, shown by the Bell Range and Foundry Company, were well worth looking at. Incidentally, it was satisfactory to note that the

lettering on the various stands was generally quite passable, and in some cases really good.

The Murray Bequest at the Victoria and Albert Museum.—The Murray Bequest, now on view at the Victoria and Albert Museum in what is officially called Room 100, but is probably much better known as one of the galleries of the old South Court, would probably have excited more interest had it not been somewhat overshadowed by the recent opening of the Salting Collection. The bequest includes, amongst other metalwork, a very interesting series of chalices, mainly Sienese and south Italian in type, a couple of good brass censers, two fine Chinese cloisonné vases, and some Italian, Sicilian, and Spanish peasant jewellery, fairly rough in workmanship, but vigorous and showing a strong family likeness. There is a collection of fans and fanmounts, and a few interesting bits of embroidery, notably an embroidered coat and a few embroidered Turkish towel-ends, eighteenth-century work, good both in colour and design. The little group of figures and vases from Meissen and other German factories, is also worthy of notice, and so are a few knives and the like with prettily inlaid handles. Altogether, though the bequest does not form a peculiarly homogeneous whole, it contains a large proportion of objects very well worth looking at. The news that £50,000 has also been left, the income from which is to be expended on the purchase of objects to be added to the collection, gives, perhaps, even greater cause for congratulation than the bequest of the collection as it stands.

EMPIRE NOTES.

The Imperial Conference.—After the Coronation of the King and Queen the most important Empire event for the year is the Imperial Conference, which is to be held in London this month. It is difficult to touch upon some of the subjects to be considered by the representatives of our Oversea Dominions without entering upon controversial matters. But there is one proposal which will be brought forward by Sir Joseph Ward, Prime Minister of New Zealand, which, it is anticipated, will, in principle, meet with the cordial approval of all. For a long time past, it has been the opinion of many of our colonial statesmen that there should be an Imperial Parliament, but although there may be much in favour of the idea, the times are not ripe for its realisation. However, the proposal that Sir Joseph will submit to the Conference may be regarded as the thin end of the wedge. It is to the effect that there should be an Imperial Council "with representatives from all constituent parts of the Empire, whether self-governing or not, in theory, and in fact, advisory to the Imperial Government on all questions affecting the interests of His Majesty's Dominions Oversea." Sir Joseph argues that this would lead towards fuller Imperial co-operation, while it would be quite consistent with the maintenance of the political autonomy of the various self-governing Dominions. The proposed Council, he considers, should be in a position to advise not only on matters of Imperial defence, but also on the commercial relations between the various parts of the Empire, and would have the advantage of affording to each part of the Empire the opportunity of expressing, through its representatives, its opinion on questions of Imperial interest.

British Investments in Canada.—The proposed Reciprocity Agreement between Canada and the United States has had the effect of calling attention to the amount of money invested by British capitalists in Canadian undertakings. Statistics show that close on £99,000,000 of British capital has been invested in Canada during the past five years. But, large as this sum is, there is every reason to believe that the supply of funds available for the further exploitation of the resources of the Dominion is by no means exhausted. It is asserted, in many quarters, that there is more money available for western Canada, at this moment, than ever previously. Canada is becoming a great magnet for investors, and the Western Provinces are recognised as affording some of the best opportunities for money-making in the world. A large number of new syndicates have been formed for development purposes, in the Prairie Provinces, during the last few months, and this in itself is strong evidence of the consistent popularity of western Canada as a field for investment.

The Development of New Quebec.—Many years ago the Canadian Geological Survey which explored the northern portion of the province of Quebec, intimated that the Huronian metalliferous formation extended far beyond the limits of Cobalt and Porcupine, and is not lost until it reaches far up into the unexplored wilds of Ungava. It pointed out that where this conglomerate rock is found all the precious and economic minerals are likely to occur, but practical men have been slow to follow up the suggestion then made. An important find, however, in northern Quebec made last autumn, in a small lake four miles long by half a mile wide —known to the Indians as Keekeek Lake—has attracted a good deal of attention. Here a quartz lode twenty feet wide, carrying very fine-grained gold was discovered. Claims were at once staked out, and now the whole surrounding territory is rapidly being taken up. If half the virtue which is claimed for this new field is proved, prospecting will, in all probability, be diverted from Porcupine to Keekeek. It is interesting to note in this connection that the Minister for Mines and Fisheries for Quebec has formed a campaign to draw the miners and prospectors into that province. The gold belt, twenty miles wide, extends from Lake Opasatika, where the Quebec Government has found tellurium, to Lake Missinable close to the trans-continental line. There appears to be little doubt as to the immense value of these auriferous deposits. The coming

season will, therefore, in all probability see the inauguration of a new Quebec, along the same line of latitude as New Ontario.

Canadian Flax for Irish Linen Manufacturers.—A letter was recently addressed to the Canadian Department of Agriculture, from a correspondent in Belfast, pointing out that Irish linen manufacturers are always looking for fresh sources of supply for the Irish markets. The present supply of flax fibre, used in the linen industry in Ireland, comes mainly from Russia, but there appears to be no reason why Canada should not provide fibre for that industry. The correspondent says:—"You grow for the seed alone, and burn the straw, but if we could get the fibre out of the straw at a fair price, it would be so much made money for your farmers. According to your statistics, the flax industry seems to be practically confined to Saskatchewan, which is so much in its favour, as it is more or less localised. My idea would be that the authorities in Saskatchewan and the railways should erect one or two mills for scutching as an experiment, and, should they prove paying concerns, others could be established afterwards. I should think the trade here would go to the expense of an instructor to give the thing a start off. The one thing certain is that there is a market here for your Canadian fibre if it can be had at a price, and anything at all is clear profit to the farmer." As the two provinces—Saskatchewan and Southern Alberta—had 476,877 acres under flax last year, the suggestion should commend itself to the Ministers of Agriculture for those provinces.

Electricity and Agriculture.—The use of electricity for agricultural purposes has been widely demonstrated in many parts of Europe and the British Empire, and Canada is anxious to prosecute the fullest inquiries into its adaptability to Canadian methods of farming. To carry out this idea, it is probable that the Ontario Government will despatch, this summer, two Commissioners to investigate the uses to which electricity is put in Europe. One of the representatives will be from the Hydro-Electric Commission, which has laid itself out to keep Canada abreast of all new electrical developments. The knowledge gained by the Commissioners will be utilised for public benefit. The proposed mission specially indicates a further and important development of the hydro-electric power project in the interests of agriculture.

Australian-Canadian Trade.—A deputation of the Melbourne Chamber of Commerce waited on the Minister of Customs for the Commonwealth recently, to urge upon the Government the desirability of taking action in the matter of reciprocity with Canada and the development of Australian-Canadian trade. This question had been brought before responsible Ministers many times before, and commercial men in Australia are coming to regard the question as one of very great importance. The Vice-President of the Chamber made the somewhat remarkable suggestion that Canada might be asked to defer the proposed reciprocity arrangement with the United States until the Commonwealth had had the opportunity of submitting a reciprocal proposal of its own to Canada. In responding to the deputation, the Minister said he would bring the matter under the notice of the Cabinet, but could give no assurance of anything immediate being done. He stated that the Imperial Conference was bound to consider reciprocity, but, with regard to the Canadian-United States treaty, interference on the part of Australia would not only be futile, but might possibly be resented.

The Commonwealth and its Silver Coinage.—The Australian Commonwealth Treasury Department recently published some figures which give an indication of the large amount of silver coin that is being circulated among the four and a half million people comprising the population of that country. A year ago an arrangement was made with the Imperial Mint, to the effect that Australia was to have the profit on its own silver coinage. An order was placed with the Home Government for £600,000 of new silver to be issued, and of this amount £392,000 has been placed in circulation within the Commonwealth. The manner in which this silver has been absorbed has struck the Treasury officials as being somewhat remarkable, as, although the additional coins in circulation number several millions, the currency has not been disturbed in any way. As a result of the ready absorption of the new issue, the Government has been unable to withdraw the £100,000 worth of old silver which it pledged itself to recall each year and to return to the British authorities. Up to the present time, only about one-fourth of that sum has been withdrawn. From the official standpoint, the coinage arrangement with the Home authority has proved most satisfactory, as by it Australia is making a large profit.

Australian Manufactures and British Manufacturers.—The various States of the Australian Commonwealth, since the beginning of the year, have been favoured with remarkably active markets in all classes of trade. This has been especially so in Victoria, where the Customs revenue has steadily expanded, and the movement appears likely to continue. There is said to be an exceptional opening for the establishment of factories in Australia at the present time, and manufacturers in this country, especially those who have hitherto been carrying on a profitable oversea business, will be well advised to examine closely the inducements offered to them to start factories of their own in that country. Among the inducements presented in the Commonwealth is the fact that there is practically an inexhaustible supply of coal and other minerals, the development of which only awaits the advent of the manufacturer and the capitalist. Further attention is drawn to the fact that it is the policy of the Government to encourage

local industries by means of protective duties, and, in some cases, by the payment of bounties and bonuses. Contracts, too, are frequently placed with local manufacturers at prices considerably higher than those which could be obtained for imported goods. Evidently there is a determination on the part of the Australian people to become, as far as possible, independent of the British, as well as the foreign, manufacturer. Statements of this kind, however disquieting in the interests of British trade, merit attention.

Natal Coal-fields.—For some time past there has been keen competition between Natal colliery owners and South African importers of Welsh coal, which, for many years, has held the mastery. There is evidence that at the present time, however, a change is taking place, for recently a statement of considerable interest to those connected with the coal industry was made before the Commercial and Industrial Commission sitting at Pietermaritzburg, to the effect that, for the majority of purposes, Natal coal had supplanted Welsh coal. In the agricultural industry, farmers who aforetime used Welsh coal, and that only for threshing, are now using the local coal. The quantity of imported coal going into Cape Town is computed at 6,000 tons per annum. It is now affirmed that the quantity of Natal coal used is more than that per month.

GENERAL NOTES.

The Wheat Industry of Manchuria.—The area of Manchuria is approximately 360,000 square miles, with an estimated population of ten to twelve millions. The present annual production of wheat is about ten million bushels, which might be increased to 300 or 400 million bushels, even with the primitive methods of native cultivation. The soil and climate are eminently favourable for wheat production. Of late years, there has been a noticeable growth in the consumption of wheat among the Chinese throughout China; and in Manchuria, in particular, a strong demand for wheat flour has arisen since the Russo-Japanese War. Flour is produced by steam roller-mills at Harbin, Changchun, Hailir, and Shuangchengpu under Russian management, at Ninguta, Aseho, and Kirin under Chinese management, and at Tiehling under Japanese management. In 1909, five million bushels of wheat passed into Harbin, of which over three millions were milled locally. The milling of wheat in Manchuria is increasing rapidly, and with cheap wheat, cheap labour, and low transportation charges, the Manchurian mills, with the steam mills at Shanghai, must inevitably capture the flour trade of the Far East.

New Port for Rome.—The Provincial Council of Rome have decided to apply to the Government for the necessary powers in order to construct a new port for the city. The locality, which has been selected after careful surveys, is at Palidoro, a small place on the coast 25 kilometres (15 miles) to the north-west of Rome, where traces of an ancient Etruscan harbour still exist. It is proposed to build two breakwaters, about 2,500 yards apart at their shore ends. The southern breakwater, which would be the longest, is to extend for about 1¼ miles into water 15 metres (about 8 fathoms) deep, and thence taking a west north-westerly direction for about 1¾ miles further, will overlap the entrance to the harbour by about 1,200 yards. The northern breakwater will run out from the shore in a parallel direction to the first for about a mile, and then, turning suddenly towards the other in a south-west direction, will leave an entrance to the harbour 300 yards wide, well protected from the Libeccio (south-west) winds. Inside the area thus enclosed will be constructed the necessary quays, etc., to which sufficient depth of water for vessels of large tonnage can be obtained by dredging. The cost of this work is estimated at 63 millions of lire (£2,520,000). The scheme also comprises the necessary sidings to connect the harbour with the existing railway at Palidoro station, also a direct line of railway, and a navigable canal to Rome.

Shale Oil Production in Australia.—Already about 1,000,000 gallons of oil from shale are being produced annually in Australia, and it is anticipated that during the course of the present year this output will be enormously increased, owing to the working of new fields and the installation of new and up-to-date machinery for treating the shale. About fourteen hundred tons of such machinery have been imported from England into New South Wales by one large company, which is already employing over a thousand men in the industry. While it is apparently much more expensive to extract oil from shale than to sink a bore and collect it as it flows, yet, as the shale is exposed, its extent and value can be estimated, which is impossible in the case of oil wells. The proved deposits of shale in Australia are so immense that they may be regarded as capable of supplying the Commonwealth with oil for centuries. Locally-manufactured kerosene from shale oil is now being used on the New South Wales State Railways, while benzine and motor spirit from the same source is being used in the motor trade, and there is also some local manufacture of candles from paraffin.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

May 17.—Professor Raoul Pictet, "Les Basses Températures."

May 24.—Frank M. Andrews, "Architecture in America." Sir Aston Webb, C.B., R.A., F.R.I.B.A., will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

May 25.—W. R. H. Merk, C.S.I., LL.D., "The North-West Frontier Province of India." The Right Hon. the Earl of Minto, K.G., G.C.S.I., G.C.M.G., G.C.I.E., will preside.

Cantor Lectures.

Monday Evenings, at 8 o'clock:—

Alfred E. H. Tutton, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." Four Lectures.

Syllabus.

Lecture III.—May 15.—*Optical Evidence of the Two Complementarily Opposite (Mirror-image) Screw Structures.* Rotation of the Plane of Vibration of Polarized Light in Contrary Directions by the Two Varieties of Quartz—Experiments on the Artificial Reproduction of the Quartz Phenomena, in proof of the suggested Screw Structure—The Twinning of Quartz and Apparent Enhancement of the Symmetry and Destruction or Modification of the Optical Activity thereby—The Interesting Case of Amethyst—The Magnificent Polarization Phenomena of Twinned Quartz.

Lecture IV.—May 22.—*Scientific and Industrial Uses of Rock Crystal.* Its Thermal and Electric Properties, and its Transparency to Ultraviolet Rays—The Construction of Prisms and Lenses (including spectacles) of Rock Crystal, and their Advantages over Glass—The Use of Quartz for Balance Weights and in connection with the Interferometer—The Artistic Use of Quartz for the Carving of Vases and other Objects—Destruction of the Crystalline Structure by Fusion, and the Uses of Fused Silica in Fibres and Scientific Apparatus.

MEETINGS FOR THE ENSUING WEEK.

Monday, May 15...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. A. E. H. Tutton, "Rock Crystal: its Structure and Uses." (Lecture III.)

London Chamber of Commerce, Oxford-court, Cannon-street, E.C., 2.30 p.m. Señor Vicente Echeverria, "The Economic Resources of Chili."

Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Discussion to be opened by Mr. S. O. Nevile on "The Desirability of Applying Greater Technical Knowledge to the Cellar Management and Retailing of Beer."

Chemical Industries Exhibition, Agricultural Hall, Islington, N., 8 p.m. Dr. S. Rideal, "Modern Methods of Water Purification."

Tuesday, May 16...Statistical, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. 1. Mr. H. D. Vigor, "On the Use of the 'Normal Crop' as a Standard in Crop Reports." 2. Mr. Frank Popplewell, "Seasonal Fluctuations in Employment in the Gas Industry."

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. W. Mott, "The Brain and the Hand." (Lecture I.)

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Mr. J. Begg, "The Architect in India."

Chemical Industries Exhibition, Agricultural Hall, Islington, N., 8 p.m. The Earl of Denbigh, "Beet-root-Sugar."

Wednesday, May 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Professor Raoul Pictet, "Les Basses Températures."

Meteorological, 70, Victoria-street, S.W., 4 p.m. 1. Dr. Hugh Robert Mill and Mr. C. Salter, "On the Frequency and Grouping of Wet Days in London." 2. Mr. E. Mawley, "Report on the Phenological Observations for 1910."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. J. E. Barnard, "A Method of Disintegrating Bacteria and other Organic Cells." 2. Mr. T. W. Butcher, "Structural Details of *Coscinodiscus asteromphalus.*"

Concrete Institute, 296, Vauxhall-bridge-road, S.W., 5.45 p.m. Mr. R. W. Vawdrey, "Reinforced-Concrete." (Lecture IV.)

Royal Society of Literature, 20, Hanover-square, W., 5 p.m. Count Lützow, "The Apostles of Moravia and Bohemia."

Chemical Industries Exhibition, Agricultural Hall, Islington, N., 8 p.m. Dr. W. P. Dreaper, "Artificial Silks and Fibres."

Thursday, May 18...Chemical Industries Exhibition, Agricultural Hall, Islington, N., 8 p.m. Mr. J. C. Smith, "Protection of Structural Iron and Steel."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Philatelic, 4, Southampton-row, W.C., 6 p.m. Mr. R. B. Yardley, "The Stamps of South Australia, with Notes on Same."

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs W. F. Cooper and W. H. Nuttall, "Some Reactions of ω-brom-methyl-furfuraldehyde." 2. Messrs. W. N. Hartley and C. H. Little, "The Course of Chemical Change in Quinol under the Action of Radiant Energy." 3. Mr. H. E. Watson, "A Method for the Accurate Volumetric Determination of the Oxygen in the Air." 4. Mr. H. D. Law, "Electrolytic Reduction. IV. Aromatic Aldehydes."

London Chamber of Commerce, Oxford-court, Cannon-street, E.C., 2.30 p.m. Mr. F. Faithfull Begg, "The Telephone: State Monopoly and Popular Control."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. N. Shaw, "Air and the Flying-Machine: The Structure of the Atmosphere and the Texture of Air Currents." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Professor Pope, "Some Scientific Applications of Photo-Micrography in Natural Colours."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. W. Aitken, "Automatic Telephone-Exchange Systems."

Historical, 7, South-square, Gray's Inn, W.C., 5 p.m. Mr. C. H. Jenkinson, "The Records of the African Slave Trade."

Numismatic, 22, Albemarle-street, W., 6.30 p.m. Mr. G. C. Brooke, "Notes on the Reign of William I."

Friday, May 19...Chemical Industries Exhibition, Agricultural Hall, Islington, N., 4.30 p.m. Dr. H. P. Stevens and Mr. Clayton Beadle, "India-Rubber."

Royal Institution, Albemarle-street W., 9 p.m. Professor R. W. Wood, "Recent Experiments with Invisible Light."

Kite and Model Aeroplane Association, Northampton Institute, Clerkenwell, E.C., 8 p.m. Mr. S. F. Cody, "How I Learnt to Fly."

Saturday, May 20...Chemical Industries Exhibition, Agricultural Hall, Islington, N., 8 p.m. Mr. J. A. Weil, "Gas-Producers."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. W. P. Pycraft, "Phases of Bird Life: Flight." (Lecture I.)

National Housing and Town Planning Council, at the Royal Society of Arts, John-street, Adelphi, W.C. Conference on Town Planning.

Journal of the Royal Society of Arts.

No. 3,052. VOL. LIX.

FRIDAY, MAY 19, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 22ND, 8 p.m. (Cantor Lecture.) ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal: its Structure and Uses." (Lecture IV.)

WEDNESDAY, MAY 24TH, 8 p.m. (Ordinary Meeting.) FRANK M. ANDREWS, "Architecture in America." Sir ASTON WEBB, C.B., R.A., will preside.

THURSDAY, MAY 25TH, 4.30 p.m. (Indian Section.) W. R. H. MERK, C.S.I., LL.D., "The North-West Frontier Province of India." The Right Hon. the EARL OF MINTO, K.G., G.C.S.I., G.C.M.G., G.C.I.E., will preside.

CANTOR LECTURE.

On Monday Evening, May 15th, Dr. ALFRED E. H. TUTTON, M.A., F.R.S., delivered the third lecture of his course on "Rock Crystal: its Structure and Uses."

The lectures will be published in the *Journal* during the summer recess.

EXAMINATION FRAUDS.

On pp. 703-6 there appears a full report of the cases tried on Saturday, May 13th, at Bow-street, in which two teachers were convicted, on their own confession, of having improperly obtained certain money prizes and medals at the Society's Examinations.

CONVERSAZIONE.

The Society's Conversazione will be held, by permission of the Trustees of the British Museum, in the Galleries of the Natural History Museum, South Kensington, on Tuesday Evening, May 30th, from 9 p.m. to 12.

The Reception, by Sir JOHN CAMERON LAMB, C.B., C.M.G., Chairman, and the other Members of the Council, will be held in the Central Hall from 9 to 10 p.m.

A Selection of Music will be performed by the Band of H.M. Royal Artillery, in the Central Hall, commencing at 9 o'clock.

A Vocal and Instrumental Concert will be given in the Fish Gallery and a Miscellaneous Entertainment in the Shell Gallery, under the direction of Mr. PATRICK KIRWAN, commencing at 9.30 p.m.

The following portions of the Museum will be open:—

The Central Hall, containing cases of specimens illustrating Mimicry; Adaptation of Colour to surrounding conditions; Protective Resemblance; etc. Also specimens illustrating the Food of Fishes, and the Life History of the Eel (East of staircase).

The North Hall, containing the collection of Domesticated Animals.

The Bird Gallery, containing groups of British Birds and Nests; and in the Pavilion, at the West end, an exhibition of the Land and Fresh-water Vertebrate Animals of the British Isles.

The Fish Gallery, containing the Great Basking Shark, the grotesque Deep-sea Fishes (case 44), the Tunny (case 38), the Tarpon and Angler-fish (case 27), and the Lemon-Sole (case 30), etc.

The Shell Gallery, including a life-size model of a Giant Squid (Newfoundland), and of a Giant Octopus (California).

The East and West Corridors on the First Floor, containing the Okapi, African Antelopes, and Giraffes.

Light Refreshments will be supplied at Buffets in the North and South Corridors on the First Floor of the Museum, and at the end of the Bird Gallery.

Visitors travelling by the District Railway (or other underground railways in connection

therewith) will be allowed free use of the company's subway, which leads from South Kensington Station direct into the grounds of the Museum.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. (These cards have now been issued.) In addition to this, a limited number of Tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5*s.* each, if purchased before the day of the Conversazione. On that day the price will be raised to 7*s.* 6*d.*

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the Offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

It will greatly facilitate the arrangements if members requiring additional tickets will apply for them at as early a date as convenient.

The Council reserve the right of stopping the sale of tickets or of raising the price, if it is found necessary, in order to restrict the number of visitors within reasonable limits.

Further particulars as to the musical and other arrangements will be given in the Programmes, which will be distributed on the evening.

PROCEEDINGS OF THE SOCIETY.

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 17th, 1911; Sir JOHN CAMERON LAMB, C.B., C.M.G., Vice-President and Chairman of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Broderick, John Carroll, 15, St. James-street, Montreal, Canada.

Craig, Eustace N., Messrs. D. & C. Rutter, Ltd., Crayford, Kent.

Hirata, Tomoh, Consulate-General of Japan, 3, Alipore-lane, Calcutta, India.

Keatinge, Sherbrooke Augustus John, M.I.Mech.E., Vineholt, Abbott-road, Lahore, India.

Ross, Alexander Carnegie, C.B., M.A., British Consulate, Buenos Aires, Argentine Republic, South America.

Subhan, Nawabzada A. K. M. Abdus, Khan Bahadur, Senior Deputy-Magistrate and Collector, Furudpore, E.B.A., India.

The following candidate was balloted for and duly elected a member of the Society:—

Beg, Mirza Faiz Husain, Kothi M. Abbas Beg, Kaiserbagh, Lucknow, Oudh, India.

The CHAIRMAN, in introducing the lecturer for the evening, said that in the year 1897 Professor Ewing delivered a series of lectures before the Society on the mechanical production of cold. In one of these he described the refrigerating machine known as the sulphurous acid machine, which was introduced by M. Pictet in 1875. In another lecture of the series, dealing with very low temperatures, and with the liquefaction of gases, he referred to the work of M. Pictet in that field in the following terms: "The attention of the scientific world was arrested in the beginning of the year 1878 by the news which reached it almost simultaneously from two sources, that two independent experimentalists had succeeded in liquefying certain of the so-called permanent gases, which had been left unliquefied in the earlier experiments of Faraday. Cailletet and Pictet, within a few days of one another, but independently, and by more or less distinct methods, succeeded in liquefying oxygen, nitrogen, and other gases. Pictet employed what we may distinguish as the cascade or successive cycle method." Professor Ewing then proceeded to describe this method, in words which it was unnecessary to repeat at that meeting. It had been necessary to wait a long time for M. Pictet himself to visit the Society, but he (the speaker) was sure those present would join in extending to him a very hearty welcome, and assuring him that his lecture would be listened to with much pleasure.

The paper read was—

LES BASSES TEMPÉRATURES.

Par M. le Professeur RAOUL PICTET.

Voici déjà plusieurs années que vous m'avez fait le grand honneur de me nommer comme membre étranger, faisant partie de votre illustre société! C'est donc avec une joie sincère que je peux aujourd'hui me présenter à vous et vous remercier personnellement de cet honneur que dans votre pensée vous avez fait autant à mon pays, à la Suisse, que vous aimez tous et depuis si longtemps, qu'à un pauvre travailleur que vous avez voulu encourager par vos suffrages tout en saluant son pays d'origine.

Merci, chers collègues, merci pour l'Helvétie, merci pour ma famille, dont un membre, Marc Auguste Pictet en fondant la Revue Britannique, fut mon parrain d'origine près de vous.

En entrant dans cette salle où vous m'accueillez avec cette vive sympathie, je sens toute ma jeunesse revivre en souvenirs charmants.

Dès mes premières leçons de physique et tout spécialement de thermodynamique je revois les figures vivantes de mes maîtres : Kelvin, professeur alors à Glasgow, Clerk-Maxwell, Tyndall, Crookes et tant d'autres dont les travaux ont été notre pain quotidien.

En 1868 je travaillais la théorie générale des machines frigorifiques à l'École Polytechnique de Paris, ce fut Lord Kelvin qui, recevant la lettre d'un simple étudiant d'école, me répondit par un vrai mémoire, approuvant mes déductions et m'encourageant à poursuivre.

Plus tard en 1876, dans l'inoubliable exposition des instruments historiques de physique, je fus reçu par cette pléiade d'hommes admirables tant par leur prodigieuse érudition que par cette affabilité légendaire et superbe dont je retrouve ici l'écho. Nommer toutes ces figures disparues hélas, serait refaire le palmarès de la vie scientifique du monde ! Vous comprenez donc, chers collègues, la joie que j'éprouve à venir vous dire merci, à serrer vos mains amies et à continuer selon mes faibles moyens cette longue tradition de rapports intellectuels qui lie depuis plusieurs siècles notre vieille Genève à la vieille Angleterre.

Et maintenant j'aborde le sujet qui depuis quarante années fait l'objet assidu de mes pensées ; je l'ai choisi à la suggestion de votre aimable secrétaire, et je l'ai accepté d'autant plus volontiers que vous entendrez dans mon exposé le "Leitmotiv" de ma vie scientifique.

Nous sommes des êtres sensitifs, pensants et qui traversons la vie avec un voile éternel devant les yeux.

Ah, connaître les choses et la raison des choses ! Associer les phénomènes révélés par l'observation, les rassembler méthodiquement, essayer de deviner l'intelligence suprême qui les a conçus, balbutier une première explication, la vérifier, constater ses erreurs, revenir en arrière, transformer les hypothèses et les redresser, recommencer la question à la Nature par de nouvelles expériences mieux disposées ; se rapprocher du but, se sentir émotionner par l'approche de parcelles de vérité et enfin avoir l'extase de quelques principes arrachés à la pensée divine, voilà le programme toujours neuf, toujours grandiose, toujours beau de la vie de notre pauvre intelligence, boiteuse, incomplète, chétive et qui rappelle dans ses élans si purs, si nobles et désintéressés la légende du "vermisseau amoureux d'une étoile."

C'est donc par l'hypothèse que notre âme tâtonne, cherche son chemin et règle la discipline de l'expérience. L'hypothèse a pour définition : "Le Roman scientifique."

En effet, l'hypothèse est un travail d'imagination. On n'observe pas une hypothèse, on la crée. Ces enfants intellectuels ont un état civil spontané, et de plus les parents, ou pour mieux dire, le père, doit être sans pitié pour sa progéniture.

Il doit exécuter sans merci toute hypothèse qui n'est pas confirmée par les faits, tirés d'expériences spéciales, cruciales, destinés à comparer les résultats découlant théoriquement de l'hypothèse de ceux qui fournissent les expériences directes observés dans le but unique de contrôle.

Or l'Univers nous montre cinq modes de phénomènes ayant des caractères bien différents et pour ainsi dire inconciliables ; les voici :

1° Les phénomènes astronomiques ;
2° Les phénomènes physiques ;
3° Les phénomènes chimiques ;
4° Les phénomènes vitaux ;
5° Les phénomènes psychiques.

L'homme d'aujourd'hui possède des bibliothèques entières nous renseignant assez exactement sur la nature concrète de ces différents modes de l'ensemble des phénomènes naturels.

La question donc que chacun de nous se pose tout naturellement est celle-ci :

Quels sont les liens communs qui peuvent réunir ces cinq modes de phénomènes divers ?

Découlent-ils tous de principes absolument différents ?

Sont-ils liés par des lois d'évolution?

La mécanique rationnelle peut-elle concevoir une hypothèse réunissant cet immense ensemble de faits ?

La question posée dès l'âge d'homme dans ma pensée, je l'ai constamment entretenue pendant les expériences ininterrompues de près de quarante ans et je veux apporter ici, très modestement, un essai de synthèse des phénomènes naturels. J'ai été dirigé dans ce travail de longue haleine par une boussole dont le pôle est le suivant :

Ne rien imaginer comme cause de mouvement que le phénomène général de l'attraction.

Ne pas accepter de forces répulsives.

Ne pas accepter de matière qui n'ait comme propriétés essentielles autre chose que :

1° Un volume dans l'espace ;
2° Une certaine résistance pour prendre du mouvement, appelée inertie ;
3° Une propriété attirante, agissant sur les matières environnantes, cause du mouvement.

Ces bases d'hypothèse m'ont paru simples, nettes et compréhensibles à tous.

Elles sont aussi les bases de la mécanique rationnelle. Nous devons donc expliquer l'ensemble des phénomènes cosmiques uniquement par des éléments tirés de la mécanique rationnelle sans aucune addition. Chaque mot employé doit être clairement défini et compris.

C'est en exécutant le programme des vérifications de cette hypothèse d'ensemble que le rôle obligatoire des basses températures m'est apparu.

C'est par les basses températures et leur emploi méthodique que les vérifications sont possibles.

Permettez-moi donc maintenant, chers collègues, d'entrer dans le vif du problème et de commencer mes démonstrations.

Je vous présenterai deux expériences en projection comme appui de mes déductions théoriques, je dois donc résumer autant que possible mon exposé pour ne pas être trop long.

I.

Je ne puis, dans le peu d'instants qui nous réunissent, vous faire un exposé complet d'une question si grave et si riche de faits et de développements de toutes natures. Je tiens seulement à vous exposer rapidement une série de jalons qui permettent actuellement de jeter des ponts entre les diverses branches des sciences physiques et font jouer aux basses températures un rôle d'une importance de plus en plus grande.

L'essai d'une méthode générale de synthèse cosmique que nous esquissons dans cette conférence, est basé entièrement sur une conception mécanique de tous les phénomènes de la nature, y compris la vie végétative. Lorsque les équations de l'astronomie, ou plutôt les fonctions générales de l'attraction universelle, exprimées pour toutes les distances, donneront une explication rationnelle de la physique et de la chimie, on pourra calculer une réaction comme on prévoit une éclipse; on déterminera une tension maximum de vapeur comme une chaleur latente, etc., ce seront des phénomènes du même ordre. La mécanique rationnelle deviendra la science universelle.

Ce résultat est le but qui ne sera probablement atteint que dans les siècles futurs; maintenant, il faut surtout préciser le problème et éviter toutes les équivoques en employant un langage précis dont chaque terme soit complètement défini.

La première difficulté très grande qui s'est présentée et qui, aujourd'hui encore, est un terrain de combat, c'est la terminologie employée dans la science actuelle pour exprimer les phénomènes. En mécanique nous avons trois unités si claires, si précises qu'elles peuvent servir sans aucune crainte d'erreur ou de confusion à exprimer tous les mouvements: l'espace, l'effort musculaire, le temps.

En combinant l'espace avec l'effort on arrive à la notion du travail mécanique. En combinant l'espace avec le temps on acquiert la notion de vitesse. En combinant la vitesse des corps, observée sous l'influence des efforts ou des forces, on obtient la notion expérimentale de la masse des corps. Et c'est tout! La mécanique n'emploie pas d'autres unités, c'est ce qui fait sa puissance, sa clarté infinie! Nous sentons dans tout notre être la mécanique par le jeu musculaire volontaire de notre corps. La conception de tous les éléments du calcul astronomique, en mécanique, se ramène en dernière analyse à des impressions sensorielles communes à tous les hommes et sur lesquelles, à l'exception de beaucoup d'autres, ils sont tous d'accord: la conscience de l'effort.

Mais en physique et en chimie, quelle confusion! Nous trouvons la température, la calorie, la conductibilité, la cohésion, l'affinité, les chaleurs latentes, les chaleurs spécifiques, etc. Tout cela doit se ramener aux trois facteurs primordiaux: espace, force, temps, et à leurs dérivés immédiats, travail, vitesse, masse. Sinon, pas de physique ni de chimie mécaniques. C'est là l'objectif actuel de la thermodynamique et de la dynamochimie.

Nous commencerons l'étude qui va nous occuper en montrant que la physique et la chimie, et tout particulièrement la chimie, ont trouvé dans la thermodynamique des facteurs puissants de développement par la production artificielle et l'utilisation des basses températures. On peut dire que dans cette direction la théorie pure et l'appareil lui-même s'unissent intimement pour constituer un domaine spécial du plus haut intérêt. Nous tâcherons de montrer le rôle caractéristique que jouent les basses températures pour hâter la solution des problèmes posés dans le sens où nous venons de l'indiquer dans cette introduction et nous partirons de là pour fonder une méthode générale de synthèse chimique.

Et d'abord, quelle est la définition de la température? A l'origine, le tact de la main était le seul thermomètre connu. Suivant les impressions perçues on disait: froid, tiède, chaud, brûlant! Comme on dit d'un tableau, il est laid, médiocre, superbe! Mesurer la température était autrefois un travail psychique

analogue à la mesure de la beauté : on appréciait une sensation.

Or, d'après ce que nous avons dit, il faut à tout prix ramener la notion de température aux éléments mécaniques, et s'arranger de telle sorte que ce soit le système musculaire du bras, et plus le tact de la main, qui mesure les températures. Pour cette partie du problème, on peut la considérer comme résolue. A l'inverse de la beauté (qui restera, heureusement, toujours inaccessible à la mécanique, précieux apanage des fonctions esthétiques de l'âme) la température est mesurable en faisant complètement abstraction des impressions tactiles. Ici nous devons entrer à pleines voiles dans les hypothèses nécessaires sur la constitution des corps et les mouvements calorifiques.

Nous admettons que les corps sont composés d'une infinie quantité de petites masses de matière appelée atomes ou molécules, suivant leur plus ou moins grande complexité. Chaque atome et molécule est noyé dans l'éther, fluide sans masse appréciable, mais parfaitement élastique et attiré fortement par la matière. La matière attire la matière suivant la fonction newtonienne, corrigée pour les distances très petites ; donc les atomes et les molécules s'attirent les uns les autres. Ils arriveraient au contact parfait si un conflit ne surgissait pas entre l'attraction de la matière pour l'éther, et celle de la matière pour la matière.

En admettant avec Lamé et d'autres auteurs que la fonction d'attraction croisse plus vite dans l'attraction de la matière pour l'éther, que por la fonction newtonienne, il résulte que deux parties constituantes d'un corps ne se toucheront pas, mais resteront en équilibre stable à une certaine distance déterminée qui ne se modifiera jamais par l'action seule de la force d'attraction. Pour bien faire entendre ce point capital dans cette théorie, imaginons, dans les espaces sidéraux supposés vides de toute autre matière pondérable, deux atomes libres de leurs mouvements et chutant l'un sur l'autre, retenus par deux dynamomètres très sensibles qui mesurent à chaque instant la force d'attraction de ces deux atomes pendant qu'ils se rapprochent : à l'infini les attractions seraient nulles ou presque nulles ; les distances deviennent-elles progressivement plus petites, les attractions croissent en raison inverse du carré des distances, la fonction newtonienne pure peut s'appliquer ; les distances sont-elles très petites, le conflit des deux attractions se fait sentir, l'effet de l'éther s'oppose à l'attraction dans le voisinage de la position d'équilibre stable ; enfin, arrivés à cette distance limite, les deux atomes seraient abandonnés sans choc par les deux dynamomètres, lesquels seraient au zéro indiquant un effort d'attraction nul. En chutant l'un sur l'autre de l'infini, distance au départ, à cette position limite voisine du contact, ces deux atomes auraient épuisé complètement leur capital d'attraction, soit leur potentiel, pour employer le mot exprimant cette notion. Ils seraient incapables de produire aucun mouvement puisqu'ils ne seraient plus sollicités par aucune force dans aucune direction.

Imaginons donc un corps constitué par l'agglomération de quelques milliards d'atomes, tous réunis ensemble dans cette position d'équilibre finale, nous aurons ainsi une masse matérielle dépourvue de tout mouvement, incapable d'en produire et représentant la mort aussi exactement que notre imagination peut se la figurer. Ce corps inerte sera au zéro absolu des températures, il sera infiniment froid. Vient-on à communiquer à ce corps de l'énergie sous une forme quelconque, en le frappant par exemple, aussitôt les parties constituantes quitteront la position d'équilibre qu'elles occupaient et se mettront à osciller autour de cette position d'équilibre ; tantôt elles se rapprocheront davantage et seront alors repoussées par l'action prépondérante de l'éther, tantôt elles s'écarteront les unes des autres et leur attraction réciproque les ramènera vers leur position d'équilibre. Nous voyons très clairement ce mouvement oscillatoire s'établir et représenter l'équivalence mécanique de l'énergie cédée au corps.

Il est clair que le centre de gravité du corps est resté immobile ; sans cela une partie de l'énergie fournie au corps se serait transformée en mouvement de translation qui rentrerait dans l'étude de la balistique et non plus dans la thermodynamique.

Nous ne nous occupons donc que des mouvements oscillatoires et ce sont eux qui vont nous fournir les définitions rationnelles de la terminologie employée en thermodynamique.

Nous avons dit en effet que nous devons ramener tous les termes sans exception aux six facteurs de la mécanique rationnelle ; les mots température, chaleur, chaleur spécifique, chaleur latente, etc., doivent donc être des dérivés directs de l'espace, de la force et du temps, combinés sous toutes les formes possibles.

Le mouvement oscillatoire que nous avons décrit comme devant être le résultat nécessaire de la transformation de l'énergie dans le corps considéré, nous fournit deux facteurs immédiats :

l'amplitude de l'oscillation, puis la force moyenne qu'indiquerait le dynamomètre si on le promenait le long de "l'orbite moléculaire" décrite par chaque particule en retenant la molécule dans sa course.

Le produit des chemins parcourus par l'attraction correspondante représente le travail en kilogrammètres accumulé par le mouvement oscillatoire de chaque molécule dans sa masse. En somme, il faut intégrer le produit des chemins parcourus par l'attraction correspondante exprimée en fonction des mêmes positions dans l'espace, faire cette intégration pour chaque molécule, faire ensuite la somme des éléments du travail pour avoir l'énergie totale actuelle du corps.

Le calcul ainsi fait se ramène aux équations de la mécanique céleste.

Appelons donc par définition :

1° Température : L'amplitude moyenne des oscillations vibratoires (projection de l'orbite moléculaire sur les trois axes).

2° Chaleur spécifique : l'attraction moyenne du corps sur la molécule considérée à un moment quelconque.

Nous aurons comme conséquences immédiates les autres définitions suivantes :

3° Quantité de chaleur. Produit de la température (espace parcouru) par la chaleur spécifique (force moyenne agissant sur l'espace parcouru) ou quantité d'énergie actuelle d'un corps.

4° La température est donc proportionnelle à la force vive des molécules d'un corps.

5° Le poids atomique de la plus petite particule du corps, servira au calcul des masses, des forces vives et des vitesses.

6° L'augmentation du volume apparent d'un corps, soit sa dilatation, servira pour mesurer une valeur approchée de sa température et de la quantité de chaleur qu'il contient, etc.

Nous n'indiquons ici qu'une partie des déductions immédiates qui se dégagent de ces hypothèses sur la constitution des corps, renvoyant pour plus de détails à un mémoire paru il y a déjà trente-deux ans sur la "synthèse de la chaleur." *

Qu'il suffise de rappeler ici que toutes les lois connues en thermodynamique se déduisent aisément des conditions initiales admises par cette hypothèse, ainsi que des définitions établies.

Plusieurs lois concernant des rapports simples entre les températures de fusion des corps, les poids atomiques, les densités, les coefficients de dilatation ont été d'abord déduites par le calcul, puis vérifiées expérimentalement plus tard. Nous appuyons sur ce point car ainsi qu'on va le voir, ce sont les mêmes idées, les mêmes hypothèses qui vont tracer les grandes lignes du rôle des basses températures en science et particulièrement en chimie.

Pour bien faire entendre ces points qui commandent toute cette étude, nous devons dès maintenant établir les démarcations essentielles qui séparent la physique de la chimie au point de vue mécanique. Lorsque ces différences fondamentales seront saisies, les rapports entre ces deux sciences jumelles n'en deviendront que plus lumineux et l'on verra que la même mécanique les embrasse et les confond dans les mêmes équations.

Reprenons pour un instant la formation d'un corps quelconque par la juxtaposition de ses éléments constitutifs tels qu'ils sont connus actuellement en chimie. Prenons 1 kilogramme de soufre par exemple. Nous ferons tomber des espaces sidéraux en un point quelconque la totalité des éléments atomiques appelés soufre et dont la masse totale correspond à celle de 1 kilogramme. Ces éléments transforment en travail de chute la totalité de leur potentiel et l'on obtient 1 kilogramme de soufre au zéro absolu de température. Faisons de même pour 1 kilogramme d'oxygène qui nous fournira, au zéro absolu, un autre corps absolument inerte mais ayant la même masse : celle de 1 kilogramme. Dans ces deux cas nous n'avons mis en activité que des potentiels physiques, c'est-à-dire des attractions qui s'exercent entre les particules ayant la même constitution intérieure. Une molécule de soufre attire une molécule de soufre, puis une autre et ainsi de suite.

De même une molécule d'oxygène attire une autre molécule d'oxygène jusqu'à l'épuisement de 1 kilogramme, somme totale du corps.

Dans ces phénomènes d'attraction l'ordre dans lequel chaque molécule vient prendre son rang n'a aucune importance, puisque toutes les molécules sont identiques entre elles.

Donc, dans tous les phénomènes physiques la répartition topographique des divers atomes d'un même corps entre eux est réglée par la pression extérieure et par la température uniquement. L'interchangeabilité de ces atomes supprime tout effet quant à leur ordre de marche sur le centre d'attraction.

Les phénomènes de condensation de l'état gazeux à l'état liquide, de l'état liquide à l'état solide, la cristallisation de tous les corps, sont le résultat de la cohésion, force qui représente

* Voir "Synthèse de la Chaleur." Archives des Sciences phys. et nat., octobre, 1879.

en physique moléculaire, la gravitation dans la mécanique céleste.

Un tout autre phénomène se passe lorsqu'une masse d'oxygène se trouve en présence d'une masse de soufre, les deux éléments en présence sont hétérogènes et le potentiel mis en activité est le potentiel d'attraction chimique ou de l'affinité.

L'expérience enseigne que les phénomènes chimiques se produisent dans des conditions tout autres :

La " condensation " du soufre avec l'oxygène exige une proportion définie dans les masses en présence.

Elle exige aussi une certaine température initiale.

Elle peut se faire entre les deux mêmes corps en plusieurs proportions et les masses engagées dans chaque combinaison sont des multiples exacts des masses premières.

Les pouvoirs d'attraction se modifient puissamment selon le degré de combinaison déjà réalisé par un corps. En reprenant notre exemple des deux masses d'oxygène et de soufre en présence au zéro absolu et en mettant ces corps au contact, on constate que, même pressés l'un contre l'autre fortement et chauffés, il faut élever très fortement la température pour que la combinaison, ou la chute chimique, de l'oxygène sur le soufre commence.

On observe en même temps deux faits :

La quantité de chaleur dégagée par le potentiel chimique pendant la réaction est très supérieure à la quantité de chaleur dégagée par le même poids d'oxygène seul condensé, plus la quantité de chaleur que fournirait la condensation du poids du soufre engagé dans la réaction. En outre l'oxygène d'une part, le soufre de l'autre, se condensent tous deux sous l'effet de températures inférieures à celle qui est nécessaire à la combinaison des deux éléments.

Il nous faut mettre ce paradoxe bien en lumière :

Puisque un certain poids de soufre en s'unissant à un certain poids d'oxygène produit plus de chaleur que la condensation des deux composants, il faut nécessairement admettre que le potentiel chimique dans ce cas est plus puissant que le potentiel physique des deux masses et pourtant la cohésion opère à une température où l'affinité des deux mêmes corps, plus puissante, ne peut produire aucun phénomène ? Comment expliquer cela ? Traduisons ce paradoxe suivant nos définitions adoptées. Un poids A d'oxygène, séparé d'un autre poids A d'oxygène par une autre distance 1, correspondant à la longueur de l'oscillation calorifique due à la température t s'associe par cohésion à cette molécule.

Ce même poids A d'oxygène attirant une masse B de soufre avec une affinité plus puissante que la cohésion de A pour A et maintenue à la même distance 1, due à la température t, ne s'associe pas au soufre. On doit élever la température, augmenter la distance moyenne de 1, et tout à coup la réunion de A B s'effectue !

En outre la réaction est très modifiable suivant les masses d'oxygène et de soufre en présence et suivant la présence d'autres corps au moment de la réaction, de l'eau par exemple.

Dans toutes les réactions chimiques, la disposition topographique des molécules entre elles, la manière dont elles sont mécaniquement apportées les unes dans le voisinage des autres, tous ces facteurs prennent une influence prépondérante sur l'issue finale de la réaction.

Ici l'interchangeabilité des atomes a disparu, il faut qu'ils se présentent à l'appel des forces d'attractions dans un ordre précis.

Toute la chimie est la constatation de ces faits généraux. Nous devons donc voir comment une hypothèse mécanique peut rendre compte de ces faits en apparence inconciliables. Cette hypothèse trouvée nous guidera ensuite dans les expériences à entreprendre comme vérification puis nous mènera après sur une piste nouvelle d'investigations.

C'est là le programme que nous allons suivre.

II.

La question posée est celle-ci: si les hypothèses physiques sur la constitution des corps, exposées dans le chapitre précédent, permettent d'envisager comme réalisable et réalisée en partie la transformation de la physique en astronomie moléculaire, quel changement doit-on y apporter pour faire rentrer dans ces mêmes hypothèses les phénomènes chimiques ?

Voici ce qu'on peut admettre comme hypothèse générale: les corps se constituent sous leurs trois états ainsi qu'il a été exposé, mais tant que le corps reste semblable à lui-même, les distances entre les centres des molécules qui s'attirent restent relativement grandes.

Met-on en présence deux corps hétérogènes, ce sont centres eux-mêmes d'attraction qui sont modifiés, ce qui oblige le corps nouveau à pénétrer profondément jusqu'au milieu de la molécule.

Pour bien comprendre cette hypothèse, grossissons plusieurs millions de fois les phénomènes moléculaires physiques et chimiques, que verra-t-on ? Des cellules organiques !

L'agglomération des cellules contigues semblables entre elles constituent les tissus, chaque cellule a son nucleus et son protoplasma qui, d'une façon très éloignée, représenterait la sphère d'éther entourant le nucleus. Le phénomène chimique correspondrait au phénomène de l' "hémogenie" ou de la fécondation cellulaire si remarquablement étudié ces dernières années par MM. Fol et Camille Pictet. Un zoosperme pénètre au travers du protoplasma de la cellule et marchant à la rencontre du nucleus, se soude avec lui pour donner naissance à l'être nouveau.

Il est clair que cette comparaison n'est qu'une grossière image du phénomène chimique primitif; elle ne sert qu'à faire saisir l'ensemble des mouvements mécaniques accomplis et la différence fondamentale entre les effets de la cohésion, réunissant entre elles les éléments identiques, et ceux de l'affinité, faisant pénétrer au centre même attractif l'atome hétérogène.

Cette pénétration dans le centre de la molécule de l'atome de l'autre corps se fera-t-elle d'une façon continue depuis les grandes distances à l'origine du mouvement jusqu'au moment de la réaction chimique? L'expérience a montré que ce n'est pas le cas. On peut mettre en contact les corps jouissant d'une grande affinité l'un pour l'autre et cependant la réaction ne s'effectue pas. Nous admettons donc dans notre hypothèse que l'affinité n'est que la continuation de la cohésion lorsque les distances deviennent encore beaucoup plus petites entre les centres qui s'attirent; c'est la valeur newtonienne de la gravitation quand la distance converge vers 0.

Dans cette hypothèse on comprend ce qui se passe pendant le trajet de chute de deux atomes hétérogènes l'un sur l'autre. Ils commencent par se rapprocher jusqu'à se trouver aussi voisins que possible; retenus à distance lorsqu'ils passent à la première limite imposée à la cohésion. Ils agissent dans cette première phase comme des corps identiques et non hétérogènes. Pour les faire passer dans la seconde période, celle de l'affinité, il faut les faire pénétrer de force dans la sphère d'éther. Alors arrivé à une certaine profondeur on observera deux phénomènes. 1° L'affinité se manifestera avec intensité à cause du plus grand réapprochement des deux centres d'attraction, et 2° la réaction de l'éther sur le corps pénétrant diminuera de toute la valeur attractive des couches pénétrées d'une façon analogue à ce qui se passe pour un corps tombant vers le centre de la terre.

En admettant ce postulat nous devons donc nous attendre à voir les deux atomes s'unir étroitement et dans un état de rapprochement excessif, intime, dès qu'ils auront franchi cette barrière qui sépare les zones d'action de la cohésion de celles de l'affinité.

Reprenons ces deux atomes munis de dynamomètres et observons le phénomène chimique comme nous avons fait pour la cohésion.

Toute la première partie de la chute des deux atomes donnera des valeurs positives d'attraction; arrivés à la distance limite de la cohésion, les dynamomètres indiqueront zéro. Nous continuons à rapprocher les atomes l'un vers l'autre, les dynamomètres exerceront une poussée et absorberont du travail mécanique. Arrivés à une certaine profondeur, la poussée diminuera et atteindra bientôt zéro.

A partir de cette position, l'affinité commence et les deux dynamomètres indiquent de nouveau une attraction tendant à rapprocher les atomes jusque vers une nouvelle limite inconnue, la distance de séparation à la fin de l'action de l'affinité étant beaucoup plus petite qu'à la fin de l'action de la cohésion.

Il convient de faire un diagramme représentant schématiquement les différentes phases de la chute complète de deux atomes hétérogènes l'un sur l'autre. Ce diagramme fera mieux comprendre l'hypothèse que nous adoptons pour l'interprétation des phénomènes physiques et chimiques et sur les quantités d'energie degagées ou absorbées suivant la position respective des masses attirantes.

Dans la Fig. 1, nous plaçons à l'origine des axes OX et OY, l'atome mobile O, tombant sur l'atome, supposé fixe M. Les ordonnées +1 +2 ou − 1 − 2 représentent les lectures faites sur le dynamomètre qui retient l'atome O dans sa chute sur M; ce sont les valeurs numériques résultantes des attractions simultanées de la matière pour la matière et de la matière pour l'éther suivant les distances.

Voici par ordre les différentes phases:

1re phase: Gravitation. L'atome O part de O′ supposé à l'infinie distance de M. L'attraction O′P′ infiniment petite au début, grandit jusqu'à la valeur OP, valeur initiale de la phase inscrite sur le diagramme de la Fig. 1.

Pendant que l'atome O chemine de O jusqu'en A, le dynamomètre inscrit des attractions tracées par la courbe PQR.

C'est la courbe newtonienne pure complétée de tous ses termes.

2me phase: Cohésion. Au point A nous voyons que la courbe inscrite sur les dynamomètres s'écarte du segment RS continuation de

la courbe newtonienne. L'action de l'éther se fait sentir et l'attraction effective diminue rapidement pour devenir nulle lorsque l'atome O est arrivé en B.

La surface du diagramme O′P′PQRS′BO′ représente la somme des travaux positifs fournis par la gravitation et la cohésion depuis les espaces sidéraux, jusqu'au zéro des températures. C'est l'expression totale du potentiel physique des deux atomes O et M. Ce potentiel ment au-dessous de l'axe des X, l'affinité débute par une absorption d'énergie extérieure.

La 2ᵉ période de la 3ᵉ phase commence lorsque l'atome O est en D et se rapproche de M jusqu'en F.

L'attraction devient active. La courbe DUF représente les valeurs successives.

La somme algébrique des deux surfaces BTD et DUM exprime l'énergie totale dégagée ou absorbée par le phénomène chimique.

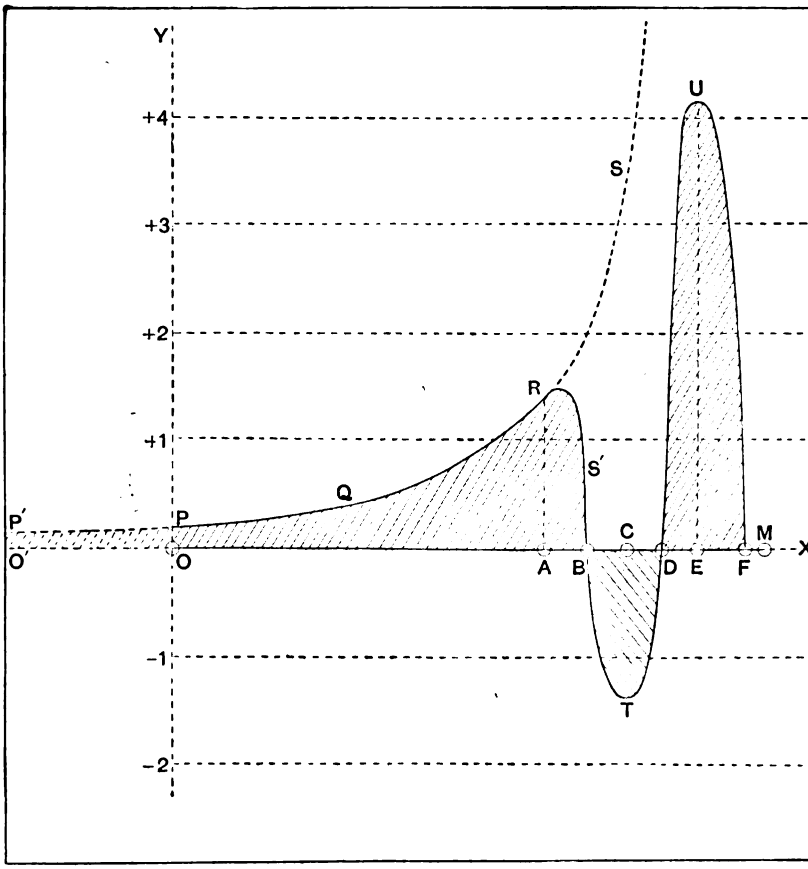

FIG. 1.

est toujours positif sans aucune exception connue.

3ᵐᵉ phase : Affinité. Ainsi que l'indique la courbe QRS′ la valeur numérique de la cohésion est arrivée à être nulle lorsque l'atome O est en B. Nous rapprochons par force les deux masses, la courbe passe sous l'axe des X. La répulsion apparente atteint bientôt son maximum lorsque l'atome O est en C, elle décroît pour être nulle en D. La surface BTD réprésente l'énergie fournie, c'est toujours un travail négatif. La 1ʳᵉ période de la 3ᵐᵉ phase s'inscrira nécessaire-

En connaissant le poids des corps engagés dans une réaction, les chaleurs spécifiques, les variations de températures ou les calories dégagées pendant la réaction, on fixera les vrais paramètres numériques de la chimie mécanique.

A priori nous ne savons rien sur la surface relative de ces différents secteurs positifs et négatifs du diagramme ; ils représentent seulement, d'une façon claire, notre hypothèse fondamentale.

Voici, du reste, la forme analytique générale sous laquelle nous pouvons l'exprimer :

En ramenant tous les phénomènes physiques et chimiques à la chute de deux masses de matière l'une sur l'autre, nous pouvons dire que ces deux masses chemineront le long de la droite qui réunit leurs centres, elles rencontreront toujours et sans aucune exception trois positions d'équilibre ; les deux positions extrêmes sont des équilibres stables, la position médiale est un équilibre instable. La première position d'équilibre s'obtient par la perte de tout le potentiel des forces physiques, gravitation et cohésion des masses, la perte du potentiel chimique fait passer les deux masses par les deux autres positions d'équilibre. Cette loi serait dans notre hypothèse absolument générale.

Avant d'aller plus loin, tirons tout de suite les conséquences expérimentales du postulat que nous venons d'exposer :

En plaçant du soufre et de l'oxygène au zéro absolu dans le voisinage immédiat, nous n'avons pas de réaction. C'est naturel, puisque arrivé aux limites de la cohésion, aucune force suffisante ne rapproche les atomes les uns des autres pour les faire entrer dans leur sphère d'affinité. Nous rappellerons ici que les efforts de compressions extérieures provoqués par les engins les plus puissants connus, produisent des effets presque négligeables rapportés aux dimensions des atomes. C'est ainsi que les efforts de dilatation des liquides font éclater n'importe quel cylindre dans lesquels ils sont enfermés.

Si au contraire on chauffe les deux corps à leur point de contact, on augmente l'amplitude des vibrations.

On sait qu'une partie de cette amplitude s'accomplit dans l'épaisseur de la sphère d'éther que c'est à cette pénétration qu'est due la répulsion apparente de l'atome. Or si l'échauffement est suffisant pour entraîner les deux atomes assez près pour qu'ils passent par le point critique où l'affinité intervient et où elle précipite plus avant les deux atomes l'un sur l'autre, alors, mais alors seulement, la réaction chimique commence.

En réalité la cohésion a passé par degrés insensibles à l'affinité, augmentant toujours sa valeur numérique réelle d'attraction, mais masquée durant un certain chemin par l'action réflexe de l'éther, prépondérante au début de l'action des forces chimiques.

Ce que nous venons de dire pour le soufre et l'oxygène peut se répéter pour tous les corps, même les plus complexes et l'on peut formuler les lois générales suivantes comme conséquences directes et logiques de notre hypothèse.

1° Tous corps hétérogènes quelconques en contact au zéro absolu ou à de très basses températures sous n'importe quelle pression, ne réagissent pas l'un sur l'autre, quelle que soit la puissance de leur affinité.

2° Deux corps hétérogènes très fortement refroidis et ne réagissant pas à ces températures, exigeront toujours une élévation de température définie pour se combiner chimiquement.

3° Plusieurs corps hétérogènes fortement refroidis et lentement chauffés se combineront d'une seule manière, si on les laisse en contact pendant le réchauffement, en admettant que l'on reste maître absolu de la température pendant la réaction.

4° La série des réactions s'effectuera suivant la ligne de plus grande pente chimique des éléments, c'est-à-dire que les premières correspondront à celles dont l'aire BTD, ou la période endothermique, est au minimum. Cet ordre ne sera souvent pas parallèle à la puissance effective totale des énergies dégagées pendant la combinaison finale.

5° Chaque atome qui pénétrera dans la région d'attraction chimique d'un autre atome modifiera immédiatement les propriétés fondamentales de cet atome ; donc en étudiant les phénomènes chimiques, on trouvera que les corps se combinent suivant les poids des atomes ; ces poids représenteront la valeur chimique de chaque corps ; ce sont les équivalents ou les poids atomiques.

Ces phénomènes chimiques sont donc fondamentalement différents des phénomènes physiques qui se passent en toutes proportions des éléments.

Nous ne connaissons actuellement pas la loi newtonnienne de l'attraction pour les faibles distances, encore moins celle de l'affinité et pas davantage celle de l'action de la matière sur l'éther. Nous devons donc uniquement, dans notre hypothèse, voir si une loi newtonienne complète, jointe à une fonction continue exprimant l'attraction réciproque de la matière pour l'éther, peu rendre compte de l'ensemble des phénomènes mécaniques tels que nous venons de les décrire.

Nous avons parlé de fonction continue comme plus d'accord avec la simplicité de l'hypothése.

L'analyse mathématique montre qu'une infinité de fonctions continues satisfont à ces conditions. Nous ne développerons pas ici ce chapitre de mathématique pure car la valeur numérique des fonctions indiquées est absolument inconnue, les constantes ne peuvent se déterminer que par un grand nombre d'expériences faites spécialement dans ce but et lorsque

la science aura fait de grands progrès dans l'art opératoire.

Devant cette possibilité d'exprimer par des fonctions continues simples les lois générales de l'attraction, nous pouvons, sans sortir de la méthode scientifique, pousser plus avant les conséquences à tirer de ces hypothèses sur la constitution des corps. Nous nous rappelons toutefois qu'un contrôle rigoureux expérimental est absolument nécessaire et que ce n'est que par un accord de plus en plus parfait entre les conséquences synthétique, que l'on peut dégager des dites hypothèses et les observations directes, que la probabilité de ces suppositions s'affirmera peu à peu.

Nous devons surtout considérer ces données comme des postulats et nous en servir à ce titre. Ce sont des principes directeurs dans l'organisation des recherches scientifiques.

III.

Utilisons donc les considérations qui précèdent dans l'analyse des phénomènes de combinaison et de dissociation en tenant compte des quantités de chaleur fournies ; nous voulons faire dans ce chapitre une étude synthétique de mécanique chimique, il faut donc voir, par le détail, le cycle complet des phénomènes et jeter tous les ponts possibles entre les facteurs divers que nous rencontrerons sur la route.

Rappelons d'abord la loi commune de la chute de tous les corps chimiques quelconques, appelée loi de Newton.

Grâce à cette loi, nous sommes en droit de représenter mécaniquement toutes les masses des corps en fonction de leurs poids mesurés par la balance.

Cette loi nous montrant que l'inertie et l'attraction sont toujours proportionnelles, quels que soient les corps chimiques étudiés, il est très probable, presque certain, que l'élément infiniment petit qui constitue le vrai noyau original de chaque corps est identique dans tous les corps, puisqu'il présente partout les mêmes propriétés fondamentales de la matière : inertie et attraction. Cette conséquence donnerait raison au vieux Pythagore qui affirmait, il y a longtemps, que tout en physique et en chimie, se calculerait un jour " par le nombre."

Il résulte de ces considérations que la force vive dégagée par toute réaction se mesurera exactement par le produit de trois facteurs : le poids des corps engagés, l'élévation de la température provoquée par la réaction, la chaleur spécifique des constituants.

En examinant le diagramme tracé par le dynamomètre pendant l'entrée en vigueur de l'affinité, nous avons vu que cette partie de la courbe présente toujours et nécessairement deux périodes : la première est négative, la seconde est positive.

Dans la première période, il faut fournir un travail extérieur, exciter la réaction.

Dans la seconde période, la réaction continue d'elle-même et fournit, produit de la chaleur.

La première période sera " endothermique," la seconde " exothermique," pour employer les mots créés par l'illustre chimiste M. Berthelot dans sa " Mécanique chimique."

Une réaction chimique de deux ou plusieurs corps est donc toujours une différence entre deux travaux mécaniques de sens contraire.

Suivant que la première période l'emporte sur la deuxième ou inversement, nous devons nous attendre à trouver deux grandes classes de combinaisons chimiques :

Dans la première, en passant des éléments constitutifs au produit final, on obtient comme somme une source de chaleur, une élévation de température, ces réactions une fois commencées sur un point quelconque du mélange intime des constituants, se propagent d'elles-mêmes dans toute la masse.

La vitesse de propagation de la réaction dépend du degré d'intimité du mélange, de la disposition topographique des atomes dans l'espace voisin du départ de la combustion. L'explosion de l'hydrogène uni à l'oxygène est un type de ces réactions exothermiques ; la combustion du bois, du charbon, etc., caractérisent aussi cette classe de phénomènes par la possibilité où l'on est de mesurer très exactement la vitesse de propagation de la réaction.

Dans la deuxième catégorie se rangent toutes les réactions endothermiques, celles qui absorberont de la chaleur pour passer des constituants au produit final.

On sait déjà, par principe, que ces réactions ne se passeront jamais d'elles-mêmes, il faudra non-seulement les exciter mais encore les alimenter. Une source d'énergie extérieure devra à chaque instant remplacer la perte subie pendant la réaction.

Nous pouvons assez exactement comparer une réaction endothermique à la charge d'une arbalète : on appuie sur la corde en fournissant du travail, puis l'arrêt intervient qui fixe la corde à fin de course. En pressant la détente on obtient le travail balistique.

On peut donc affirmer que tous les produits obtenus par cette seconde catégorie de réactions contiennent plus d'énergie potentielle que les constituants, ils représentent la grande classe

des accumulateurs dans le sens le plus général du mot.

Ces produits chimiques conduisent immédiatement à la notion des explosifs.

La formation de l'eau oxygénée par l'action de l'acide chlorhydrique sur le bioxyde de baryum indique bien l'allure des réactions endothermiques. Il se forme du chlorure de baryum dégageant +11 calories, tandis que l'eau oxygénée absorbe −11·6 calories. La chimie abonde en cas analogues.

Il va sans dire que les décompositions de tous les produits obtenus provoqueront des phénomènes inverses mécaniquement parlant à ceux qui se sont manifestés pendant la combinaison.

Il est par conséquent possible de prévoir par ces hypothèses :

1° Toutes les lois de la dissociation.

2° L'influence des températures et des pressions sur les décompositions chimiques.

3° Les conditions de la stabilité.

4° L'ordre dans lequel les réactions de différents corps s'effectueront en fonction des températures.

5° Réciproquement l'ordre des dissociations, etc.

6° Les doubles décompositions, conséquences des lois de Berthollet, se déduisent également de ces considérations et l'on peut calculer à l'avance les chaleurs perdues ou gagnées suivant la température à laquelle se passe la réaction.

En somme d'une façon générale l'accord entre les conséquences que l'on peut déduire des hypothèses et les faits consacrés par l'expérience est suffisant pour que nous ayons entrepris une série d'observations dont le cadre a été dicté par ces principes mécaniques.

IV.

La première série d'expériences a consisté à démontrer qu'aux très basses températures la réaction de tous les corps hétérogènes juxtaposés est nulle, même si l'on obtient un contact intime en pulvérisant les corps ou en les serrant fortement l'un contre l'autre.

Ces expériences ont donc pour objet essentiel de prouver que, dans toutes les manifestations de l'affinité, la première période est endothermique.

Nous avons choisi pour commencer naturellement les corps dont l'affinité réciproque est la plus énergique.

Dans notre laboratoire de Berlin nous disposons d'appareils à marche continue qui nous permettent de produire et de conserver indéfiniment de très basses températures.

De grands cylindres à double enveloppe servent d'enceintes froides. Nous en avons huit de dimensions variables, les uns horizontaux, d'autres verticaux.

Les uns sont utilisés pour la condensation des gaz et des vapeurs sous des pressions variant de 200 atmosphères jusqu'au vide presque absolu.

Dans la double enveloppe, nous introduisons les divers liquides volatils qui servent à obtenir les basses températures ; un groupe de cinq compresseurs agissant " en compound " aspirent et compriment les vapeurs de ces liquides et refroidissent les cylindres à n'importe quelle température que l'on désire, comprise entre la température ambiante et −213° au-dessous de zéro, température extrême obtenue par le *vide* sur " l'air atmosphérique liquide."

Il est impossible d'obtenir d'une seule fois des abaissements de température aussi considérables.

Nous refroidissons les corps au moyen de trois cycles successifs fonctionnant chacun entre des limites de température pas trop écartées.

Le premier cycle fonctionne au moyen d'un mélange d'acide sulfureux anhydre et d'acide carbonique. Ce liquide, introduit dans la double enveloppe des cylindres, permet de les refroidir à −100° facilement. Les vapeurs sont reliquéfiées dans des serpentins noyés dans de l'eau ordinaire courante, et le liquide ainsi reconstitué sert à alimenter l'opération frigorifique, car il suffit d'entr'ouvrir légèrement un robinet reliant le bas du condenseur avec la double enveloppe pour que le liquide volatil se précipite de lui-même dans cette enceinte où la pression est infiniment plus faible. Il y prend instantanément la température correspondant à la pression des vapeurs dans cet appareil.

Des manomètres à mercure facilitent la connaissance exacte, et pour chaque instant, des phénomènes intérieurs et indiquent la température par la pression.

Les différents cylindres verticaux que nous avons spécialement fait construire pour toutes les expériences du premier cycle sont au nombre de quatre.

Le plus grand a 350 millimètres de diamètre intérieur et 1·350 m. de hauteur.

Le plus petit a 160 millimètres de diamètre et 200 millimètres de hauteur.

Les autres sont intermédiaires.

Le deuxième cycle fonctionne au moyen du protoxyde d'azote ou de l'éthylène.

Pour obtenir ces gaz à l'état liquide on se sert du premier cycle et des basses températures qu'il procure. On liquéfie dans l'un des cylindres horizontaux refroidi à −80° le protoxyde d'azote, par exemple, sous une pression de 6 à 12

atmosphères ; nos appareils peuvent en fournir 25 à 30 kilogrammes à l'heure.

Ce protoxyde d'azote liquide, et déjà très froid, passe dans la double enveloppe d'un autre cylindre vertical. Lorsqu'on fait le vide dans cette double enveloppe, il s'y évapore en cristallisant et en abaissant la température jusqu'à $-135°$ et $-150°$.

Les vapeurs aspirées par un groupe de deux compresseurs sont incessamment reliquéfiées pour retourner dans le cylindre réfrigérant sous forme liquide.

Ces deux cycles sont entièrement fermés, continus et fonctionnent aussi longtemps qu'on le veut à toutes les températures comprises entre les limites indiquées. En reglant la vitesse relative des compresseurs, et en modifiant, suivant les besoins, les ouvertures des vannes placées sur les canalisations des vapeurs, il est aisé de régler la marche des appareils d'une manière mathématique.

Les deux cycles fonctionnent bien plus facilement qu'une machine à haute température au point de vue de la régularité et de la souplesse des manœuvres.

Chaque compresseur possédant son moteur à vapeur special, le régime de la marches s'établit progressivement, les ouvriers mécaniciens attachés au laboratoire étant tout à fait formés à ces diverses opérations.

Le troisième cycle est obtenu par la liquéfaction de l'air atmosphérique dans un tube horizontal refroidi au-dessous de $-120°$ par le jeu du deuxième cycle.

Une pompe à glycérine comprime 700 litres d'air à la pression de 200 atmosphères dans le tube central du réfrigérant du deuxième cycle.

La pression tombe à 90 atmosphères et l'air se liquéfie. En laissant sortir cet air liquéfié dans une petite enceinte déjà refroidie à l'avance on atteint $-210°$ à $-213°$ à la limite extrême du vide établi dans l'enceinte.

Ce dernier cycle est encore intermittent et pas fermé comme les deux premiers.

Il donne chaque heure environ 1 k. 500 d'air liquide, la compression de l'air jusqu'à 90 au 200 atmosphères exigeant toujours un temps assez long.

Nous venons de décrire d'une façon très sommaire l'appareil avec lequel nous produisons et maintenons les basses températures, nous rentrons dans notre sujet.

Dans le réfrigérant du deuxième cycle nous introduisons dans des éprouvettes de verre les substances chimiques suivantes, absolument pures :

1° Acide sulfurique 95 p. 100 de concentration.

2° Soude caustique pulvérisée très fine.

3° Potasse caustique id. id.

4° Ammoniaque en solution aqueuse 23 p. 100 en poids d'ammoniaque.

5° Acide nitrique fumant.

6° Sel marin pulvérisé très fin.

Après avoir laissé plusieurs heures tous ces produits se refroidir jusqu'à $-125°$ environ, nous avons mis en présence, dans un cristallisoir refroidi, les corps suivants dans l'ordre ci-après.

A.—*L'acide sulfurique et la soude caustique.*

L'acide sulfurique a été extrait de l'éprouvette en verre en cassant celle-ci avec une pince en acier ; le bloc d'acide sulfurique solide est tombé dans la poussière de soude et au moyen d'une baguette de verre on a fortement agité le mélange et pressé les corps mécaniquement de telle sorte que les petits morceaux de soude avaient pénétré dans le bâton d'acide solide.

Nous n'observons aucune réaction quelconque, les corps restent absolument inertes.

J'avais disposé une forte bobine Ruhmkorff pour obtenir des étincelles de 30 à 35 millim. de longueur. Deux fils isolés et tenus dans un tube de verre, conduisaient le courant et l'étincelle à l'extrémité des deux fils découverts où elle jaillissait sur une longueur variable à volonté.

Nous avons constaté que l'acide sulfurique solide conduisait très bien l'étincelle que nous obtenions tout le long du bâton, un des fils étant fixe à une des extrémités.

Pendant plus d'un quart d'heure nous avons fait passer l'étincelle et nous avons vu que la réaction ne s'opérait qu'au point exact où l'étincelle jaillissait sans se propager à toute la masse.

Nous avons alors sorti l'éprouvette du froid et l'avons laissée exposée à l'air ambiant.

La température est assez vite remontée, mais avant que l'acide sulfurique fut fondu, la réaction s'est subitement déclarée dans toute la masse et l'éprouvette en verre s'est cassée par suite de la haute élévation de température qui a accompagné cette réaction en masse.

Nous pouvons approximativement fixer à $-80°$ ou $-85°$ la température où la réaction en masse a pris naissance.

Le fait principal est établi : aux basses températures, pas de réaction entre ces deux corps sans le secours d'une énergie étrangère qui, dans ce cas, est l'influence de décharges électriques.

B.—*Acide sulfurique et potasse caustique.*

Nous pouvons répéter ici exactement ce que nous venons de dire pour la réaction *A* avec

cette seule différence que la réaction en masse a commencé à une température plus basse que pour la soude caustique—peut-être $-80°$ ou $-90°$. Les déterminations exactes de ces valeurs de la température sont encore à faire car elles offrent des difficultés toutes spéciales.

C.—*Acide sulfurique et ammoniaque.*

Ici encore les mêmes allures générales des phénomènes, action nulle au départ, la réaction se produit sans se développer aux basses températures au-dessous de $-65°$, puis subitement la réaction en masse élève la température du tout au-dessus de $+100°$.

D.—*Acide sulfurique et sel marin.*

Même allure que *C*; sauf la fin qui a été moins violente. La réaction n'a commencé à marcher d'elle-même qu'au-dessus de $-25°$.

E.—*Acide nitrique fumant* 89 *p.* 100 *et soude caustique.*

Au premier contact pas de réaction pendant peut-être 30 à 40 seconds, puis commencement lent avec élévation de température des points en travail, enfin violente et brusque transformation de la masse avec dégagement de vapeurs rutilantes.

Ici l'opération a commencé d'elle-même sans l'influence de l'étincelle électrique sous le seul effet de l'élévation de la température hors de l'appareil, pour éviter l'action des vapeurs sur les instruments.

La réaction s'est effectuée en trois minutes environ à partir de la sortie de l'appareil froid.

Le dépôt de vapeur d'eau aux surfaces de contact de la soude et de l'acide a probablement facilité et excité la réaction en masse.

F.—*Acide nitrique fumant* 89 *p.* 100 *et potasse caustique.*

Exactement la même allure que pour *E* peut-être un peu plus rapide, le premier contact avant la réaction en masse a cependant duré plusieurs secondes.

G.—*Acide nitrique fumant et sel marin.*

Réaction nulle jusqu'à $-74°$. Depuis ce moment et avec le secours de l'étincelle électrique, la réaction commence. Elle ne devient une réaction en masse que vers $-20°$.

De cet ensemble de faits il ressort avec une grande clarté :

1° Que les corps chimiques ne se combinent pas directement aux basses températures, sans le secours d'énergie étrangère.

2° Que la réaction en masse succède toujours à une période pendant laquelle la réaction a lieu seulement par places électives, dans lesquelles on fournit l'énergie électrique ou calorifique.

3° Que la température basse est parfaitement réglable et maintenable, soit lorsque les corps n'agissent pas encore, soit lorsque la réaction ne s'opère que sur les places électives.

4° Que la température se relève brusquement sans qu'on puisse en être maître, au-dessus de la température limite à laquelle commence la réaction en masse.

5° Les températures pour lesquelles on peut obtenir et conserver la réaction limitée, sont d'autant plus basses que les affinités des corps mis en présence sont plus grandes et le contact des corps plus intime.

Il résulte de cette partie de notre étude que l'expérience a pleinement confirmé les previsions dégagées logiquement de nos hypothèses. Toute réaction chimique commence nécessairement par une période endothermique. Cette période est plus ou moins longue suivant les réactifs ; on peut la régler par le seul jeu de la température.

En présence des affinités puissantes des corps jouant le rôle principal en chimie, l'emploi des basses temperatures s'impose comme un facteur ayant une valeur intrinsèque, et qu'il est impossible de remplacer par aucun autre agent physique.

De même que pour la liquéfaction des vapeurs, la température joue un rôle caractéristique, équivalent à celui d'une variable indépendante dans une équation, de même dans l'affinité amenant la réaction chimique, nous retrouvons les mêmes lois, les mêmes fonctions spéciales de la température que pour les phénomènes de la cohésion, origine et cause des liquéfactions.

Ces considérations mécaniques réunissent donc dans le même chapitre la gravitation, la cohésion et l'affinité, toutes trois se manifestant comme le développement normal de deux fonctions continues représentant l'attraction de la matière pour la matière et pour l'éther.

Avant de passer à des opérations de synthèse chimique proprement dite, nous avons voulu observer quelques phénomènes de basse température pour répondre à certaines questions qui se posent de suite dés l'entrée en matière dans ce domaine.

Et d'abord un premier point : si l'on refroidit suffisamment les corps pour les rendre solides ou tout au moins pâteux, ce changement d'état n'est-il pas la cause efficiente de l'absence de réaction. En somme ne serait-il pas possible d'obtenir une réaction même à basse température si les corps en présence gardaient la forme liquide ou gazeuse ? Secondement : si l'on s'adresse à des réactions très sensibles comme l'action des acides sur la teinture de tournesol, l'action des

alcalis sur la phénolphtaléine, réactions qui paraissent développer au simple contact avec une période endothermique très faible, pourra-t-on les annuler par les grands froids ?

Dans cette direction nous avons fait les préparations suivantes :

1. *Acide sulfurique et carbonate de chaux* (*marbre pilé pur*).

Nous avons choisi la solution d'acide sulfurique qui reste liquide à la plus basse température, sa formule est $H_2SO_4 + 7_2HO$ refroidie à $-70°$ et restant liquide à cette température. Le marbre en poudre était refroidi, de son côté, à $-89°$. On jette le marbre dans l'acide sulfurique.

Aucune réaction pendant plus d'une demi-heure.

A $-52°$ en laissant lentement remonter la température on aperçoit les premières traces de réaction.

Le dégagement augmente progressivement jusqu'à $-15°$.

De $-15°$ à $-7°$ la réaction est de plus en plus énergique et devient turbulente avec mousse abondante.

2. *Acide sulfurique et carbonate de soude.*

Les cristaux de carbonate de soude refroidis à $-85°$ sont jetés dans l'acide sulfurique $SO_4H_2 + 7H_2O$ liquide à $-83°$.

Nous remuons fortement avec une baguette de verre refroidie et nous constatons que la réaction est nulle.

Nous laissons remonter la température à $-56°$ où la réaction apparait. De petites bulles commencent à se dégager.

A $-30°$ le dégagement est bien nettement établi et à $-23°$ la réaction est turbulente et générale.

3. *Acide sulfurique et chlorure de baryum.*

L'acide sulfurique est refroidi à $-115°$ restant liquide. Le chlorure de baryum est dissous dans l'alcool peu étendu et refroidi à $-135°$. On jette dans l'acide sulfurique la solution alcoolique de chlorure et des cristaux de chlorure de baryum en agitant le mélange.

L'acide sulfurique laisse surnager les cristaux mais ne se trouble nullement, on ne peut distinguer aucun voile dans la liqueur.

A $-70°$ la réaction commence et à partir de ce point elle s'accentue de plus en plus.

4. *Acide chlorhydrique et nitrate d'argent.*

Nous prenons de l'acide chlorhydrique ayant 33 p. 100 et ne gelant pas à $-130°$.

Le nitrate d'argent est dissous dans l'alcool et reste liquide à $-125°$. On mélange les deux liquides, aucune réaction. Vers $-109°$ la liqueur commence à se troubler. Audessus la réaction devient générale.

5. Réactions très sensibles des acides sur la teinture de tournesol.

Acide sulfurique et solution dans l'alcool de la teinture de tournesol bleue.

Nous refroidissons l'acide à $-140°$ ainsi que la solution alcoolique qui est pâteuse.

En les mélangeant ensemble intimement au moyen d'une baguette de verre refroidie, la solution reste bleue indéfiniment.

En laissant remonter la température, la couleur passe au violet vert $-110°$ sans atteindre le rouge.

Ce n'est qu'à $-105°$ que le rouge vif apparaît.

En faisant la même expérience, mais en plongeant dans la liqueur à $-120°$ degrés une baguette de verre ayant la température ambiante, nous avons vu se produire un cylindre rouge vif au sein de la liqueur au contact des parois de la baguette. La réaction s'est produite sur une profondeur de 2 à 3 millimètres autour du cylindre de verre.

Acide chlorhydrique et solution alcoolique de tournesol.

L'acide reste liquide à $-140°$. Nous y jetons la solution pâteuse de tournesol et nous mélangeons.

La liqueur reste parfaitement bleue sans changement.

A $-115°$ la coloration violette apparaît et se change en rouge vif à $-110°$.

6. *Réaction sensible des alcalis sur la phénolphtaléine.*

On sait que la phénolphtaléine donne avec les plus petites traces d'alcali une belle couleur rouge foncé ; cette réaction est souvent utilisée pour les titrages de potasse et de soude.

Nous faisons séparément deux solutions dans l'alcool absolu de potasse caustique et de phénolphtaléine.

Nous vérifions qu'aux températures ambiantes la réaction rouge apparaît instantanément puis nous refroidissons les deux éprouvettes à $-145°$. Les deux solutions sont visqueuses à cette basse température.

Nous les mélangeons intimement une fois refroidies.

Aucune réaction, pas trace de coloration rouge.

A $-100°$ la teinte rosée commence à se manifester, à $-90°$ la coloration est complète.

7.—*Sodium et potassium sur l'alcool hydraté.*

Nous refroidissons du sodium métallique à $-80°$ ainsi qu'une éprouvette pleine d'alcool à 84 p. 100 en poids et 16 p. 100 d'eau. En jetant le sodium dans l'alcool nous constatons que le sodium reste brillant sans aucune attaque.

La réaction commence à $-48°$ et se développe

alors assez vite à cause de l'élévation spontanée de la température.

Pour le potassium nous opérons de même et nous constatons que de $-80°$ à $-70°$ il n'y a aucune réaction.

La réaction débute assez brusquement à $-68°$ environ et part avec énergie plus violemment qu'avec le sodium.

8.—*Acide nitrique fumant et alcool.*

On sait que cette réaction est très énergique aux températures ordinaires. En mélangeant ces deux liquides refroidis séparément à $-88°$ il n'y a pas de réaction. Elle ne commence qu'à $-70°$ et vers $-60°$ elle devient vive et brusque.

RÉSUMÉ.—Nous pouvons résumer l'ensemble des recherches faites dans cette direction ainsi que suit :

1° Entre les températures comprises entre $-155°$ et $-125°$ nous n'avons pu constater aucune réaction chimique, quelle que soit la nature des corps mis en présence.

2° Les réactions sensibles, comme l'effet des acides sur la teinture de tournesol, etc., se produisent à plus basses températures que d'autres réactions très énergiques, sodium métallique sur l'acide sulfurique par exemple.

3° Dans toutes les réactions chimiques, nous pouvons trouver deux phases suivant la température à laquelle on opère :

A. La réaction lente qui se produit au-dessous d'une température limite, spéciale pour les corps mis en présence ; cette réaction se manifestant sous l'influence de l'étincelle électrique ou spontanément suivant l'écart qui existe entre la température actuelle et cette température limite.

B. La réaction en masse, dans laquelle l'élévation de température produite par les parties qui réagissent, communique aux parties voisines assez de chaleur pour les faire aussi réagir ; c'est une sorte d'embrasement général qui n'est modéré que par les conditions physiques imposées au rapprochement des particules qui se combinent.

Dans la plupart des cas, pour obtenir et conserver la réaction lente, il faut enlever par rayonnement la chaleur développée par la combinaison, sans quoi la température passe très vite à la limite de la réaction en masse.

4° L'étincelle électrique semble être le meilleur excitant pour provoquer la réaction lente.

5° Il est donc expérimentalement constaté que toute réaction chimique commence toujours par une période d'énergie négative, c'est-à-dire dans laquelle il faut fournir du travail extérieur aux composants pour permettre leur combinaison.

Le travail chimique appelé par M. Berthelot travail préliminaire ou préparatoire, est donc un fait général dans la nature.

V.

Après les confirmations expérimentales qui précèdent et qui n'ont d'autre but que de donner quelque poids aux hypothèses émises et adoptées comme postulat, nous allons décrire d'autres expériences guidées directement par ces vues théoriques et destinées à "conduire les premiers essais de synthèse chimique par l'emploi rationnel des basses températures."

Les premières observations ont été faites pour obtenir les composés nitrés du toluène, de la naphtaline et du phénol par des réactions à basses températures.

Dans les réactions sur le toluène et la naphtaline, nous avons pris des températures suffisamment élevées pour que la réaction se fasse spontanément sans le secours d'énergie étrangère. Nous avons introduit par très petites quantités dans un mélange de SO_2H_2 et NO_3H le toluène ($C_6H_5-CH_3$).

Dans la troisième série d'expériences sur le phénol, nous sommes descendus au-dessous de la température limite pour le départ de la réaction en masse et nous avons mélangé dès le début les corps composants dans les proportions définies à l'avance, après les avoir refroidis.

L'étincelle électrique a été employée pour provoquer la réaction limitée jusqu'à épuisement des produits.

Voici les résultats obtenus, soit aux températures ordinaires d'environ $+30°$ à $+35°$ soit aux basses températures entre $-50°$ et $-55°$.

On sait que le toluène forme deux dérivés isomères lorsqu'on le soumet à l'action de l'acide nitrique, partageant du reste cette propriété avec tous les produits contenant le groupe CH_3 en chaîne secondaire.

Ces deux dérivés sont :

1° L'ortho-nitrotoluène liquide aux températures ordinaires et bouillant à $+222°$.

2° Le para-nitrotoluène solide jusqu'à $+54°$ et bouillant à la température de $+237°$.

Ces deux produits sont très difficiles à séparer par rectification à cause du voisinage de leur point d'ébullition.

Un de ces deux groupes doit sûrement correspondre au travail maximum de l'énergie de constitution, un de ces dérivés doit être le résultat du "travail par la plus grande pente chimique."

C'est ce dérivé certainement que nous devons accroître en faisant la réaction aux basses températures.

Plus nous opérons à basse température, plus ce produit doit l'emporter en quantité relative sur l'autre.

La loi chimique déterminant la position des groupes entrant dans le noyau, suivant la composition moléculaire déjà existante, est formelle ; nous ne pouvions guère nous attendre à voir intervenir d'autres groupements atomiques mais bien une différence dans le poids des produits obtenus. Sur 100 parties en poids traitées, nous trouvons aux températures de $+30°$ $+35°$.

Orthonitrotoluène . .	60 p. 100
Paranitrotoluène . .	40 p. 100
Total . .	100 parties.

Pour opérer aux basses températures, c'est goutte à goutte que nous avons laissé tomber la solution de toluène refroidie à $-50°$ $-55°$ dans le mélange froid de SO_4H_2 avec NO_3H.

Nous avons énergiquement remué pour répandre le liquide introduit dans la masse et après la réaction finie laquelle n'a pas pu élever la température d'une façon très appréciable, vu la marche continue des appareils frigorifiques, nous avons procédé à la séparation fractionnée dans le vide.

Nous avons alors obtenu :—

Orthonitrotoluène . .	86 p. 100
Paranitrotoluène . .	15 p. 100

Le rapport en poids des deux dérivés s'est donc totalement modifié car nous avons :

A $+35°$ 1·5 d'orthonitrotoluène par rapport au paranitrotoluène ; à $-50°$ nous trouvons 5·5 pour la proportion relative des mêmes produits.

La seconde série de synthèses a porté sur les composées de la nitronaphtaline.

Nous avons pris les méthodes qui, aux températures ordinaires, ne donnent que ce produit pur, avec seulement des traces des autres composés parallèles ; l'influence des basses températures dégagerait le sens des plus grandes affinités.

Nos prévisions n'ont point été déçues et les réactions à basses températures ont fait apparaître des combinaisons toutes nouvelles dans un semblable milieu.

L'opération a consisté à refroidir à $-55°$ un mélange d'acide sulfurique concentré et d'acide nitrique fumant. Puis on laisse tomber dans le liquide pâteux de la poudre fine de naphtaline refroidie. En agitant fortement, la réaction s'opère et l'on empêche l'élévation de température par le fonctionnement des appareils frigorifiques qui maintiennent les enveloppes du cylindre, servant de puits à réaction, bien au-dessous de $-50°$, vers $-90°$ environ. Le rayonnement suffit pour enlever toute la chaleur produite.

Voici les résultats curieux et nouveaux obtenus :

Nous n'avons que :

20 p. 100 d'x-nitronaphtaline au lieu de 100 p. 100 obtenus à haute température. Ce corps fond à $+61°$.

28 p. 100 de x-dinitronaphtaline et

40 p. 100 de y-dinitronaphtaline dont le point de fusion est à $+144°$.

12 p. 100 de naphtaline non transformée.

Jusqu'à présent on n'avait obtenu la y-dinitronapthaline que par l'emploi transitoire de la dinitro-x-naphtylamine. Il est intéressant de l'avoir obtenue par voie directe et en si grande proportion.

Cette réaction donne donc à ce produit une place spéciale au point de vue des affinités mises en jeu.

La troisième série d'expériences a été faite par l'emploi de l'énergie auxiliaire de l'étincelle électrique.

Nous avons opéré sur le phénol par l'acide nitrique.

Afin de bien constater l'effet des basses températures nous avons commencé par chercher expérimentalement le point où la réaction en masse des deux produits a encore lieu.

Faisant d'abord la réaction à 0°, nous avons mêlé ensemble progressivement 160 grammes d'acide nitrique de 1·34 comme densité, étendu de son double poids d'eau, avec 80 grammes de phénol fondu, le ballon et ses annexes étant toujours maintenus dans la glace pilée. On lave le liquide obtenu, et on distille par l'emploi du vide et des vapeurs d'eau. On sépare ainsi les deux produits : l'orthonitrophénol du paranitrophénol.

En opérant deux fois : la première ainsi qu'il vient d'être dit, la seconde en plongeant le ballon à $-40°$ seulement, nous avons constaté que la réaction à $-40°$ était assez vive pour faire remonter subitement la température à $-20°$ dans le ballon de verre. La réaction en masse se produisait encore à $-40°$.

Les deux essais, dans ces conditions, ont fourni la même quantité de paranitrophénol environ 6 grammes.

Après cet essai nous avons fait le suivant. Nous avons pris 160 grammes d'acide nitrique d'une densité de 1·34 non étendu, refroidi à $-45°$ $-50°$. Nous avons fait une solution de phénol dans l'éther sulfurique refroidie aussi à $-45°$ $-50°$. En mélangeant ces deux solutions

froides il ne se passa pas de réaction immédiatement, mais après quelques instants une véritable explosion chassa le contenu du vase jusqu'au plafond du laboratoire, la réaction en masse venait de se produire. Par contre le temps perdu entre le mélange et l'explosion prouvait que nous étions bien près de la température limite cherchée.

Cette expérience nous amena au dernier essai suivant: Réduisant de moitié les quantités engagées, nous congelâmes 80 grammes d'acide nitrique, densité 1·34, à la température de $-50°$ à $-60°$ et 40 grammes de phénol fondu, répandu progressivement dans la masse sous forme aussi divisée que possible. La température basse était rigoureusement conservée. Aucune réaction ne se manifesta, nous étions au-dessous de la température de réaction en masse. Alors nous servant de l'étincelle électrique, nous avons fait traverser le mélange par le courant en ayant soin de ne jamais exagérer à la même place le passage des étincelles.

La réaction totale a eu lieu progressivement sans aucune élévation de température apparente, vu ces précautions.

Après la distillation et la séparation methodique par rectification des deux produits, nous avons trouvé 15 grammes de paranitrophénol, soit une préparation cinq fois plus forte si on la compare aux poids des composants mis en présence aux températures normales.

Outre ce produit nous avons fait à haute et basse température le métanitrophénol.

En passant par le dinitrobenzène et la métanitraniline sous l'action de l'hydrogène sulfuré dans une solution ammoniacale, puis en diazotant la métanitraniline, les réactions obtenues à basse température ont donné un rendement double comparativement aux résultats des opérations similaires à la température ambiante.

Il résulte de tous ces faits que, par le choix convenable des basses températures, nous avons modifié d'une façon profonde toutes les réactions concernant la nitrification du toluène, de la naphtaline et du phénol.

Nous sommes occupés à compléter ces travaux de chimie synthétique pour en dégager des lois numériques, avec mesure des paramètres, afin de les présenter sous une forme pratique et immédiatement utilisables dans les laboratoires.

Ce que nous venons de dire suffit pour nous permettre d'esquisser la première charpente encore rudimentaire d'une méthode générale de synthèse chimique.

VI.

Les faits que nous venons d'exposer d'une façon très concise corroborent complètement l'espoir que nous avions de voir les phénomènes chimiques transformés et modifiés par l'emploi rationnel des basses températures.

Nous allons tâcher de résumer les conséquences qui découlent, tant des hypothèses émises que des vérifications déjà faites, pour asseoir les premiers jalons d'une méthode opératoire permettant d'obtenir par voie synthétique et certaine tous les corps de la nature.

En prenant tous les corps simples connus et les plaçant en présence aux très basses températures, nous savons qu'ils ne réagissent pas l'un sur l'autre.

Il faudra commencer par faire la table expérimentale des températures auxquelles les réactions commencent, toutes les autres conditions restant du reste les mêmes (mélange, pression, éclairement, etc.).

Il faudra de même étudier au-dessous de cette température tous les effets chimiques dus aux divers excitants connus; étincelle électrique, corps chauds, réactions auxiliaries, etc.

On formera ainsi la 1re table de dynamique chimique: le chemin de plus grande pente des éléments chimiques. On saura par cette table à quelle température exacte il faut porter un corps en présence d'un autre pour n'avoir qu'une seule solution au problème chimique.

On passera ensuite aux composés binaires, réunis à un corps simple et l'on opérera exactement de la même façon que précédemment. Ce sera la 2e table dynamique. La 3e table dynamique donnera l'ordre des réactions des corps binaires en contact avec les corps binaires à toutes les températures, etc.

Lorsque le nombre de ces observations sera considérable, les lois de ces réactions apparaîtront avec la même netteté que celles que l'on connaît aujourd'hui. Ces lois du reste en font partie, seulement d'une façon confuse puisqu'elles procèdent du mélange de toutes les tables dynamiques.

Nous pouvons donc opérer plus tard ainsi que suit:

Nous voulons produire un corps ayant par exemple: A atome d'hydrogène, B d'oxygène, C d'azote, et D de carbone, etc.

Nous connaissons déjà par les tables le noyau le plus ancien, c'est-à-dire celui qui se forme à la température la plus basse, se rapprochant du corps demandé.

Pour ajouter à ce noyau de l'oxygène, du carbone ou de l'azote, nous connaissons les réactions caractéristiques provoquant ces réactions et les températures minima nécessaires pour ne permettre que celles-là.

Nous utiliserons successivement toutes les tables et les lois qui les accompagnent pour grossir la molécule primitive de tous les affluents que nous voulons lui faire recevoir. En empêchant les réactions en masse, en ne produisant que des réactions limitées et précises, la conduite des opérations présentera le caractère de nécessité puisqu'il sera toujours le fidèle écho de la ligne de plus grande pente des composants.

Il est clair qu'une semblable étude embrasse des années de recherches préliminaires. Il faut classer des milliers de phénomènes qui se succèdent degré par degré ; tous les facteurs les plus variés interviennent.

En somme, nous décrivons une méthode synthétique reposant sur la série ascendante des phénomènes dus à l'affinité par ordre de date, si le temps croît en fonction des températures. Le chemin est unique et ne doit nulle part présenter d'ambiguité.

Le rôle des basses températures est double ; d'une part elles paralysent toutes les réactions, sauf celle que l'on veut produire, d'autre part en enlevant au fur et à mesure qu'elles se forment, les quantités de chaleur dues à l'affinité transformée en chaleur, elles empêchent la température de s'élever et de favoriser des réactions perturbatrices que l'on ne pourrait plus maîtriser.

On déduit de ces faits une règle qui doit diriger la construction des appareils à réactions chimiques synthétiques. La puissance frigorifique de ces appareils doit être considérable et leur fonctionnement modifiable à volonté, soit comme température, soit comme effet en calories enlevées.

De plus il faut pouvoir introduire dans l'intérieur des masses refroidies, soit sous forme liquide, soit sous forme de poudre, mais en quantités réglables les corps servant de réactifs, refroidis eux-mêmes au préalable.

Enfin les "excitants" doivent pouvoir opérer dans l'intérieur des "chambres froides" et leur action doit être aussi facilement réglable que la marche des appareils frigorifiques.

Avec une pareille disposition, l'étude synthétique des phénomènes chimiques peut entrer dans une voie parfaitement méthodique, bien que longue et complexe.

Lorsque dans un laboratoire aux températures ordinaires on mélange les divers réactifs ensemble, il est souvent très difficile de prévoir l'issue de la combinaison. Chaque réaction élémentaire apporte avec elle son énergie qui n'est pas éliminée et permet à d'autres réactions plus complexes ne se manifester, celles-là, elles aussi, interviennent pour établir de nouvelles relations dynamiques entre ces substances diverses en voie de formation ; et de ce conflit général, de cette confusion mécanique, sort le plus souvent un mélange contenant un peu de tout ce qui a pu se former en route ! La température s'est quelquefois élevée de plus de 100°, l'état naissant de certains corps associés aux énergies calorifiques disponibles fait de la réaction totale un vrai chaos ; bien habile le chimiste qui peut prévoir dans ces conditions ce qu'il trouvera dans son creuset !

Nous pensons avoir démontré par tout ce qui précède que la chimie trouvera dans l'étude parallèle des réactions et des conditions thermiques qui les sollicitent, un terrain d'une fécondité inattendue et qui permettra de diriger les recherches d'une façon tout à fait méthodique. Avec les basses températures réglables à volonté, on oblige tous les agents chimiques à garder le silence, on les musèle ; en laissant progressivement remonter la température et en portant dans le milieu refroidi une source d'energie sous forme d'un excitant, on permet à chaque corps d'opérer à son tour, par ordre de puissance.

Les combinaisons s'opèrent ainsi d'une façon rationnelle et prévue. On part d'un noyau primitif pour arriver au corps cherché, sans craindre des dégâts produits accidentellement par le conflit chimique.

Nous croyons que le rôle des basses températures pour les synthèses chimiques ressort clairement des hypothèses que nous avons exposées au début de ce travail et qui semblent de plus en plus se confirmer par l'étude expérimentale.

VII.

Après avoir suivi notre hypothèse et étudié ses conséquences en astronomie, physique et chimie, nous devons, toujours par les mêmes méthodes, poursuivre nos investigations dans l'ensemble des phénomènes biologiques.

Nous avons vu que les phénomènes totaux de la matière morte peuvent être ramenés à l'équation de Newton, complétée par les lois de l'attraction de la matière pondérable s'exerçant sur l'éther.

La vie et ses manifestations caractéristiques peut-elle rentrer dans le cadre de ces conséquences synthétiques, découlant directement de notre hypothèse fondamentale . . . c'est la question.

Précisons le problème en fixant nettement les phénomènes spéciaux, distinguant l'apparition non équivoque de la vie. La somme de ces caractères spéciaux servira de définition à la vie.

1° Tous les êtres vivants, plantes ou animaux,

nous apparaissent sous forme de types spéciaux appelés espèces. Le nom de l'espèce doit accompagner n'importe quel être connu, vivant ou mort.

L'étude des transformations successives des espèces, ou le darwinisme, ne fait qu'illustrer ce fait général.

2° Chaque individu représente toujours une unité ayant une valeur intrinsèque.

3° La conscience de sa propre existence par l'individu n'est pas nécessaire ; chez les animaux supérieurs et chez l'homme en particulier, elle est le fait normal.

4° Les phénomènes physico-chimiques qui se passent dans la profondeur des tissus des êtres vivants paraissent constituer comme résultante un état d'équilibre stable qui correspond à la vie normale des êtres et garantit leur individualité contre la somme des forces extérieures.

5° La vie normale des êtres représente toujours trois phases : la naissance et la croissance jusqu'à l'âge adulte, la vie normale, la vieillesse se terminant par la mort.

6° Les maladies, dans le sens le plus général du mot, sont produites par toutes les influences quelconques qui troublent l'équilibre stable des phénomènes vitaux, au delà des limites qui peuvent être assignées comme normales.

7° Les phénomènes vitaux eux-mêmes, ramenés à leur expression la plus simple, sont toujours caractérisés par des phénomènes chimiques et pas physiques.

Pour les plantes on trouve la cellule absorbant sous l'influence de la lumière l'acide carbonique de l'air ou de l'eau et le décomposant en carbone fixé et en oxygène rendu à l'extérieur.

Pour les animaux, on distingue aussi la cellule absorbant l'oxygène de l'air et le fixant aux substances qui s'introduisent dans cette même cellule par endosmose.

La nutrition et la respiration des cellules, voilà les deux phénomènes constants chez tous les êtres vivants.

Tous les mouvements volontaires ou non, toutes les perceptions sensorielles dues au système nerveux, sont des caractères variables et peuvent complètement faire défaut sans que la vie puisse être considérée comme absente ou éteinte.

Après avoir rappelé, dans ce qui précède, les faits qui nous paraissent dominer la biologie et qui doivent partout et en toute occasion se manifester pour qu'on puisse dire avec certitude, il y a là un phénomène vital, nous allons voir de quelle façon on peut organiser les recherches sur l'influence spéciale de basses températures sur les phénomènes vitaux.

Dans les expériences progressives du froid sur la série des différentes espèces animales il faudra noter l'ordre dans lequel les principales fonctions se modifient.

Pour les êtres supérieurs on devra en particulier enregistrer avec soin :

1° L'état mental, l'action de la volonté, de la mémoire, les perceptions diverses, la vitesse des mouvements réflexes, la valeur de l'erreur personnelle pour l'homme, les variations dans l'intensité des sensations, les limites du pouvoir musculaire, l'anesthésie progressive de la peau, etc.

2° Pour les êtres chez lesquels le contrôle des phénomènes psychiques est impossible, il faut surtout s'attacher aux mouvements observables des différents éléments mobiles ; cils vibratiles, mouvements réflexes dus à la douleur et aux excitations électriques, dilatation de l'iris, mobilité des membres, mouvements péristaltiques de l'intestin, etc.

3° Autant que possible, il faudra aussi enregistrer les effets produits par le même milieu refroidi au même degré sur le même type, type d'animal pris dans les trois phases caractéristiques de sa vie, jeunesse, âge mûr, vieillesse.

On constatera ainsi les points faibles de chaque phase et l'action spécifique des basses températures sur l'organisme s'accentuera encore davantage.

4° Au fur et à mesure que l'on descend dans la série des êtres, les mouvements vitaux se simplifient pour en arriver aux actions chimiques élémentaires des cellules. On touche aux infusoires et aux microbes.

Leur développement sous l'influence des basses températures doit être surveillé avec tout le soin que comporte aujourd'hui la microbiologie ; l'effet du froid sur une longue série d'êtres, tous soumis à ces influences perturbatrices, peut être entrepris, grâce à l'extraordinaire rapidité de la reproduction de ces germes, bacilles et microbes !

Les spores, les diatomées desséchées, les foraminifères, et tous ces êtres qui jouent un rôle analogue à celui des graines dans le règne végétal, peuvent donner lieu aux expériences les plus concluantes sur certains problèmes de la vie, que nous exposerons comme conclusion de ce mémoire.

Expériences sur les Végétaux Vivants.

De même que pour les animaux, nous devons tracer le cadre des expériences concernant les plantes et tous les végétaux.

Pour chaque plante, depuis le sommet de l'échelle, avec les dicotylédones, les marronniers,

les chênes, au bas de l'étage des cryptogames et des algues, il faut examiner avec précision les variations des phénomènes vitaux dus au refroidissement.

Dans cette catégorie d'êtres on trouve les mêmes règles et les mêmes faits que pour les animaux :

Les plantes munies de leurs feuilles et en pleine floraison sont aussi frileuses, si ce n'est plus, que les mammifères les plus délicats !

Si on les plonge, même un peu de temps, dans l'atmosphère glacée, elles périssent avec une vitesse effrayante.

Il est donc nécessaire de graduer le froid et son intensité avec non moins de précautions que pour les animaux.

L'observation simultanée de l'action de la lumière du soleil sur la chlorophylle et celle de la chlorophylle sur l'acide carbonique au même instant, est de la plus haute importance, car c'est le phénomène capital caractérisant la vie végétative des plantes. L'observation des effets du froid sur les racines, les bourgeons, les fleurs, l'évaporation, etc., devra être consignée pour les différents états d'âge des végétaux. Enfin une étude toute spéciale de l'action des grands froids sur les graines permettra de rapprocher dans une même série d'observations les végétaux à leur origine et les animaux en germes.

J'ai pensé qu'il convenait, avant d'attaquer ces problèmes en coupe réglée, de faire ce que l'on fait pour les mines, on force des puits de sondage en différentes places pour connaître la puissance du filon ; ensuite on ouvre les galeries.

En tête du questionnaire que chaque homme porte comme bagage, toute sa vie durant, on trouve toujours quelque question ayant un caractère philosophique, sur le confin de la métaphysique et de la science pure. Une de ces interrogations puissantes est celle-ci : Qu'est-ce que la vie ? D'où vient-elle ? Est-ce quelque principe spécial tombé, on ne sait d'où, spontanément sur terre et qui, tout à coup, a organisé la matière, créé ces types divers, donné à chaque être ce pouvoir mystérieux de procréer lui-même de nouveaux êtres semblables à lui !

La vie peut-elle être appelée spontanément dans la matière inerte ?

La vie a-t-elle pour emblème ce feu sacré des vestales brulant toujours sur l'autel ?

Si ce feu vient à s'éteindre, comment le rallumer ?

Ce problème de la vie est un des plus anciens ; il reste toujours un de plus modernes ; on peut dire cependant que la solution a fait un pas en avant sous l'influence des basses températures et de leur emploi méthodique en chimie et en biologie.

Nous allons d'abord exposer les résultats généraux obtenus durant des recherches qui remontent déjà à bien des années et s'échelonnent de 1869 à 1891. Une partie de ces expériences ont été faites en collaboration avec MM. Casimir de Candolle, Edouard Sarasin et E. Yung, du Bois-Reymond, Bertin, Susani, etc.

D'autres, toutes récentes, complètent quelques termes de la série.

Résultats expérimentaux.

Mammifères supérieurs. Le chien a été l'animal choisi pour quelques recherches.

Un chien de taille moyenne pesant 8 kilogrammes et demi environ, à poils ras, est placé dans le puits frigorifique refroidi à $-90°$, $-100°$, les appareils fonctionnant de telle sorte que cette température est constante.

Le chien est placé sur un fond de bois garni d'un sac de toile. Sa queue et son museau ne touchent pas les parois métalliques du puits, tendues à l'intérieur d'un cylindre de toile formé par les parois d'un grand sac relevées tout autour de l'animal.

Dans cette expérience un thermomètre est fixé dans l'aine du chien, dont la patte de derrière est solidement fixée contre l'abdomen avec plusieurs doubles de flanelle.

La peau ayant été rasée, un excellent contact est établi entre le réservoir du thermomètre, ayant une forme cylindrique, et la circulation générale de la bête, la flanelle et la position du chien font que le réservoir du thermomètre occupe à peu près la position centrale du puits frigorifique et qu'elle se trouve très protégée contre le rayonnement. La tige du thermomètre est assez longue pour permettre des lectures continues à 35 centimètres au-dessus du chien.

Voici maintenant les observations générales recueillies. Nous ne donnons pas de chiffres de détails, nous en tenant seulement à la marche des phénomènes.

La température du chien étant normale et l'animal ayant mangé deux heures avant le début de l'éxpérience, on introduit le chien dans le puits refroidi à $-92°$.

Dès la première minute on observe une augmentation progressive de la rapidité de la respiration et de la fréquence du pouls.

Ces accélérations vont en s'accusant pendant 12 à 13 minutes, à mon étonnement je constate d'abord au thermomètre une augmentation de température d'environ un demi-degré.

L'animal donne des signes d'agitation.

Après 25 minutes, la température est lentement revenue à son point de départ.

Le chien mange avec avidité du pain qu'il refusait péremptoirement avant le début de l'expérience.

La respiration est toujours très active, fréquente et profonde.

Après 40 minutes les extremités des pattes sont très froides, mais la température s'est maintenue à peu près constante, oscillant avec deux à trois dixièmes de degré près autour de +37°.

Après 1 heure 10 minutes, le chien ne marque plus d'agitation sensible, mais respire fort et tend à faire quelques mouvements avec les pattes maintenues par les cordes, efforts suivis de calmes complets, sauf la respiration.

La circulation est un peu plus rapide que précédemment, on sent les pulsations du cœur bien nettes à l'artère carotide.

Les extrémités se refroidissent encore plus.

Pendant la demi-heure suivante la bête a mangé environ 100 grammes de pain et les conditions générales indiquées plus haut ont varié. La temperature s'est abaissée d'un demi-degré tout au plus.

Tout à coup, en quelques instants, la respiration se ralentit, le pouls devient fuyant et la température s'abaisse avec rapidité.

Vers 22° on retire l'animal sans connaissance du puits et tous les soins pour le rappeler à la vie sont inutiles.

L'extrémité des pattes est déjà gelée.

Le chien est mort en moins de deux heures par rayonnement de sa chaleur, et par les effets perturbateurs causés par ce refroidissement excessif.

D'autres animaux, chiens et cochons d'inde, ont toujours manifesté dès leur entrée dans le puits frigorifique, cette augmentation dans la fréquence de la respiration et des battements du cœur ; dans les cas observables, une légère élévation de la température intérieure s'est toujours produite.

Nous pouvons conclure de là que l'équilibre stable des mammifères vivants provoque dans l'organisme normal, en face de ce facteur subit, une réaction formidable. Lorsque l'individu menacé perd sa chaleur par rayonnement avec une telle énergie, il semble que la conservation automatique de l'animal provoque une absorption d'oxygène plus que normale ; les fonctions de la digestion repartent avec vigueur et, à la menace des effets du froid, les organes répondent par un travail inverse : une surproduction de chaleur et d'énergie.

Probablement que les tissus connectifs, graisses, etc., se réabsorbent rapidement pour donner au sang les principes hydro-carburés attaqués par l'oxygène ; l'apparition de la faim a toujours été signalée après un quart d'heure d'expérience.

Lorsque la déperdition de chaleur devient toujours plus considérable, l'individu organisé inconscient fait le sacrifice des membres périphériques. La circulation s'arrête dans toutes les extrémités, elles sont mortes les premières.

Puis, presque tout à coup, la circulation centrale s'arrête elle-même, lorsque l'abaissement de la températures est à 8° à 10° au-dessous de la normale. La chute finale brusque indique et prouve l'énergie du combat engagé par l'individu vivant contre le facteur qui vient perturber l'équilibre vital.

Une étude approfondie de ces phénomènes reste à faire, car elle est d'un enseignement capital relativement à certaines fonctions du système nerveux central, et sur les causes de la combustion lente dans la circulation sanguine.

Refroidissement d'un Organe.

J'ai essayé sur moi-même l'effet du refroidissement de la main par rayonnement.

J'ai plongé le bras nu jusqu'au-dessus du coude dans le puits frigorifique maintenu à −105° sans toucher les parois métalliques.

On sent sur toute la peau et dans toute l'épaisseur des muscles une impression tout à fait caractéristique et spéciale qu'aucune description ne peut faire entendre. On éprouve une sensation, pas désagréable d'abord, mais qui le devient peu à peu et dont le siège a l'air d'être l'os central ou le périoste.

Le mot "se refroidir jusqu'à la moelle" semble prendre une signification nouvelle et vécue. Au bout de 3 à 4 minutes la peau du bras est un peu violacée, mais la douleur devient forte et gagne surtout les parties profondes. Au bout de 10 minutes, après avoir sorti le bras du puits frigorifique, on éprouve en général une forte réaction avec cuisson superficielle de la peau.

En maniant longtemps de la neige avec les bras nus, la réaction cutanée subséquente ressemble, en plus affaibli, à cette cuisson qui apparaît à la fin de l'expérience décrite.

Expérience sur les Poissons.

Les poissons rouges, les tanches et généralement les poissons d'étangs d'eau douce peuvent être complètement gelés puis dégelés sans mourir. L'expérience demande cependant à être faite avec ménagement.

Si l'on congèle lentement, dans une atmosphère de $-8°$ à $-15°$, des poissons de cette catégorie, en ayant eu la précaution de laisser ces poissons quelque vingt-quatre heures dans de l'eau à 0°, on peut former un seul bloc compact de cette eau et des poissons qu'elle contient.

En brisant une partie de la glace et mettant à nu un de ces animaux, on constate qu'on peut le casser en petits morceaux comme s'il était lui-même fait de glace.

On peut donc admettre que tous les poissons du même bloc ont la même apparence intérieure et qu'ils sont tous gelés au même degré.

En laissant lentement fondre cette glace et les poissons qu'elle renferme, on voit ceux-ci nager après comme avant sans aucun signe de malaise apparent.

Au-dessous de $-20°$ l'expérience ne réussit plus avec les poissons rouges et les tanches.

Nous n'avons pas examiné encore la série des poissons à cet égard.

Expériences sur les Batraciens.

Les grenouilles subissent un refroidissement et une congélation de $-28°$ sans crever.

A $-30°$ et $-35°$ la plupart cessent de vivre.

Expériences sur les Ophidiens.

J'ai refroidi un serpent commun des champs appelé vulgairement lanwoui, à $-25°$, il a survécu, mais, refroidi à $-35°$, il est mort.

Expériences sur les Scolopendres.

J'ai refroidi à $-40°$ trois scolopendres qui ont parfaitement résisté au traitement et ont vécu une fois dégelés.

Soumis à $-50°$ ils ont aussi résisté.

Refroids une troisième fois à $-90°$ ils sont morts tous les trois.

Expériences sur les Escargots.

Ayant refroidi trois escargots, fournis par M. le prof. E. Yung de l'Université de Genève, dont deux présentaient quelques fissures à la plaque fermant leur coquille, nous les avons refroidis à $-110°$ à $-120°$ pendant bien des jours.

Les deux escargots légèrement fendus sont morts, celui qui était intact a survécu au traitement et a échappé à la mort, grâce probablement à son opercule intact.

Expériences sur les Œufs d'Oiseaux.

Tous les œufs d'oiseaux refroidis au-dessous de $-2°$ à $-3°$ meurent et ne peuvent être couvés ; si on ne les refroidit que jusqu'à $-1°$, ils survivent.

Expériences sur les Œufs de Grenouilles.

Ces œufs, refroidis lentement à $-60°$, peuvent revivre et donner éclosion aux têtards. Si le refroidissement est brusque ils meurent. Il est très essentiel de mettre au minimum plusieurs heures pour obtenir l'abaissement complet de la température.

Expériences sur les Œufs de Fourmis.

Ces œufs, pris pendant la saison chaude, sont très sensibles au froid.

Suivant l'état d'avancement de la larve de l'insecte dans l'œuf, le refroidissement peut être plus ou moins grand.

Entre 0° et $-5°$ tous les œufs ont été tués. Nous avons eu aussi des œufs avancés, tués par une température de $+5°$ maintenue quelques heures.

Expériences sur les Œufs de Ver-à-Soie.

Nous avons fait un très grand nombre d'expériences, grâce à une installation industrielle que nous avons organisée en Italie septentrionale, pour la conservation des graines de ver-à-soie.

Ces œufs sont assez résistants, surtout si dès la ponte ils n'ont jamais eu de commencement de développement. Lorsque ces œufs pondus sont placés immédiatement dans la chambre froide, on peut les refroidir à $-40°$ sans leur faire perdre leur pouvoir de développement. Il se passe même dans ce cas un phénomène intéressant : les œufs refroidis, puis soumis aux conditions de température normale pour leur éclosion, dès que le printemps a garni les mûriers de leurs feuilles, ne présentent presque jamais les maladies si fréquentes aux œufs de vers-à-soie abandonnés à eux-mêmes et subissant plusieurs mois durant les fluctuations des températures ambiantes.

Les parasites de toutes espèces, vrais microbes des œufs du ver, ne trouvent pas, dans ces conditions, un terrain favorable à leur développement, et la chenille sort indemne de tous ces accidents si redoutables pour elle et si redoutés par toute l'industrie de la soie.

Le refroidissement artificiel des œufs de ver-à-soie est entré dans la grande industrie, vu ces avantages bien positifs.

Du reste tout ce travail découle directement des belles recherches de Pasteur sur les vers-à-soie.

Expériences sur les Infusoires.

Des rotifères, et toute la série ordinaire des infusoires qui se développent normalement par le séjour de quelques durée de végétaux dans l'eau stagnante, ont été gelés dans l'eau où ils pullulaient, puis abaissés à $-80°$ et $-90°$

A cette température, maintenue pendant près de 24 heures, une grande partie des habitants sont morts.

A $-60°$, au contraire, ils ont tous vécu, autant que leur dénombrement était possible.

Une dernière expérience faite à $-150°$, $-160°$ n'a plus laissé dans l'eau dégelée que des cadavres.

Expériences sur les Protozoaires, les Microbes et les Graines, les Diatomées, etc.

Grâce à l'obligeance de M. Casimir de Candolle et de quelques autres naturalistes, j'ai pu me procurer à différentes reprises des graines sèches en bon état d'une foule de plantes diverses.

De même, grâce à plusieurs zoologistes: MM. Fol, Miguel, E. Yung, MM. Pasteur et Roux de Paris, M. le Professeur Koch de Berlin, etc., j'ai pu rassembler une collection complète de microbes, de diatomées, de micrococques, de bacilles, de spores, dont la nomenclature serait ici fastidieuse.

Plus de 30 à 35 espèces de microbes, un plus grand nombre de graines, de diatomées, etc., ont été soumis, dans une série d'expériences, à des températures de plus en plus basses.

Une partie de ces recherches ont déjà été publiées dans les archives, les dernières expériences faites à Berlin sont encore inédites.

Dans toutes ces recherches, sans exception aucune, les refroidissements les plus excessifs et les plus prolongés ont donné des résultats négatifs; c'est-à-dire que les germes, graines, microbes, spores, bacilles, diatomées, micrococques etc., se sont tous développés après ces refroidissements comme ils le font normalement, sans aucune différence appréciable.

Les spores ont donné naissance à toute la série de leurs bacilles, les diatomées ont émis leurs filaments protoplasmiques ou pseudopodes, les graines ont germé et poussé des bourgeons et des plantes vigoureuses, etc. En un mot, les graines et les œufs des animaux, qui leur servent de parallèles dans l'autre règne, semblent défier les froids les plus intenses.

Dans la dernière série d'expériences, les graines et les bacilles ont été placés à près de $-200°$ dans l'air liquéfié et se sont développés de la même façon que les mêmes graines et germes conservés aux températures extérieures.

Les cils vibratils du palais des grenouilles, soumis aux mêmes expériences, ont cessé de vibrer lorsque le froid a dépassé $-90°$. Une fois réchauffés et dégelés ils recommençaient à exécuter leur mouvement pendulaire.

Les vaccins seuls et les cultures connues sous le nom de ptomaines, à l'exception de toutes les substances organisées, semblent beaucoup souffrir des grands froids. Les vaccins deviennent stériles.

On sait du reste que les vaccins ne contiennent pas de microbes ni de spores.

L'influence des basses températures trace ainsi une ligne de démarcation intéressante entre ces grandes classes de substances virulentes: les microbes et les vaccins.

Conclusions.

Il se dégage de cette première série d'observations, encore bien incomplète et remplie de lacunes, quelques conséquences générales que nous essayerons de résumer ici:

1° Il est certain que plus on prend les phénomènes vitaux à leur origine, dans les organismes les plus simples et les plus primitifs, plus le refroidissement peut être poussé loin, sans amener plus tard de modifications appréciables dans le développement des individus refroidis.

2° En formant une échelle des êtres, depuis les plus inférieurs jusqu'aux mammifères, on constate qu'une échelle analogue établit les températures minima que ces êtres peuvent supporter.

Au fur et à mesure que l'organisation se complique, les froids intenses deviennent plus à redouter pour l'individu.

3° Chez les animaux supérieurs le refroidissement brusque dans un bain d'air froid provoque une réaction énergique, très caractéristique et qui pourra peut-être conduire à des méthodes thérapeutiques utiles à l'homme dans certaines maladies.

4° Enfin une conclusion d'un ordre philosophique se dégage de cet ensemble de faits relativement aux idées générales qu'on peut se faire sur la vie.

Nous avons démontré qu'aux basses températures voisines de $-100°$ tous les phénomènes chimiques, sans aucune exception, sont anéantis et ne peuvent plus se produire. Donc les actions chimiques qui, par principe même et définition, doivent se manifester dans la profondeur des tissus, pour que nous puissions y reconnaître la présence de la vie, sont supprimées *ipso facto* à $-200°$ dans tous les germes, graines, spores, etc.

Nous nous trouvons ainsi au moment où l'on réchauffe ces organismes refroidis à $-200°$, dans d'excellentes conditions pour caractériser un des côtés principaux de la vie, à savoir si elle prend naissance spontanément dans un organisme mort préexistant.

Si la vie, semblable au feu des vestales, devait

disparaître à jamais de l'organisme une fois qu'on l'aurait laissée s'éteindre, ces germes une fois morts (et ils le sont à $-200°$) devraient rester morts ! Au contraire, ils vivent, ils se développent comme si ce refroidissement n'avait pas eu lieu.

Donc la vie est une manifestation des lois de la Nature au même titre que la gravitation et la pesanteur. Elle est toujours là, elle ne meurt jamais, elle demande pour se manifester l'organisation préexistante. Celle-ci obtenue, chauffez, mettez l'eau, la lumière, et de même qu'une machine à vapeur dans ces conditions se met à fonctionner, le germe vivra et se développera.

On sait que jusqu'à ce jour, ni spontanément, ni artificiellement, l'homme n'a jamais vu sous ses yeux se former ce premier organisme où la vie jaillit comme d'un puits artésien. Pour créer cet organisme, il faut nécessairement s'adresser à la vie, et voilà pourquoi le cercle est encore vicieux, la question reste ouverte.

Si l'on pouvait créer de toutes pièces une structure organisée morte, les conditions physico-chimiques suffiraient pour y développer tous les phénomènes vitaux de la vie végétative.

L'étude des phénomènes vitaux par l'emploi méthodique des basses températures permet donc de faire rentrer la vie au nombre des forces constantes de la Nature.

VIII.

Nous en arrivons maintenant à l'examen des phénomènes psychiques.

On peut affirmer qu'aucun phénomène sensoriel conscient caractéristique du monde psychique ne peut s'observer sans l'existence préexistante d'un système nerveux chez l'individu observé. Les arbres, les muscles, les cils vibratils mêmes sont le centre de phénomènes biologiques mais nous ne retrouvons aucun symptôme de pensée.

Les animaux seuls et surtout les animaux supérieurs, les mammifères sont le siège constant de ces phénomènes sensitifs et psychiques.

Nous savons que tous les organes des centres nerveux congelés à basse température, ne présentent plus aucun phénomène psychique ; toutes les réactions sont supprimées totalement endormies.

Par l'examen direct des animaux soumis à de très basses températures quelques uns seuls ont repris vie. Les escargots, quelques serpents, les œufs de papillons, quelques poissons mêmes ont survécu.

Nous pouvons donc affirmer que la mort de la vie intellectuelle et psychique est le cas général quand l'organe des centres nerveux a été refroidi puis réchauffe ; mais nous constatons aussi des modifications profondes et traumatiques dans la structure élémentaire des éléments constitutifs des tissus.

Les cellules ont éclaté par congélation et au réchauffement suivant les basses températures, elles n'ont point été réparées.

Ainsi l'organe ayant été maltraité, la question de la suppression des phénomènes psychiques ou de leur réapparition dans un organe sain d'une façon spontanée après le réchauffement reste ouverte. Pour les serpents, les escargots et les infusoires et en somme une foule d'espèces d'animaux inférieurs, l'intensité des constations psychiques est plutôt faible, mais ils ont des sens déjà assez développés et des instincts très surs. Outre cela ils savent se diriger, choisir leur chemin et montrent souvent des combinaisons très intelligentes dans leurs actes.

Si on peut donc affirmer que la vie intellectuelle ou psychique de ces êtres a repris spontanément avec la reprise des phénoménes physico-chimiques qui se passent dans la profondeur des centres nerveux, il faut admettre qu'ils sont plus résistants que ceux des êtres supérieurs et ne se laissent pas désagréger par les basses températures.

Par induction, mais sans aucune certitude, on pourrait en conclure que si un homme pouvait être réfroidi à $-200°$ et ensuite réchauffé sans avoir perdu la vie végétative, les phénomènes psychiques se représenteraient comme en temps normal et cela en proportion de l'état indemne dans lequel on retrouverait les centres nerveux. La vie psychique, c'est-à-dire l'âme, reprendrait possession de son centre naturel avec tous ses caractères.

A ce sujet il est important de ne laisser aucune méprise se glisser dans ces conséquences tirées d'expériences scientifiques.

Nous affirmons hautement ici que l'âme est une personnalité pensante habitant un milieu spécial, mais n'est pas le milieu.

L'âme n'est pas une chose, mais nous ne la connaissons que lorsqu'elle se manifeste dans une chose : le cerveau.

Voici une comparaison qui fera bien comprendre toute notre pensée.

Voyez ce télégraphe automatique tel qu'on le rencontre dans tous les hôtels à Londres et ailleurs ; vous entendez un déclic et l'appareil se met à marcher, il enrégistre sur une bande de papier les nouvelles à chaque instant.

Eh bien, le télégraphe et le papier sont la chose, et sont l'équivalence du cerveau.

Le sens de la dépêche en est l'âme !

Ce sens habite dans l'appareil, est compris dans les caractères et l'outil merveilleux qui imprime les lettres des phrases. Mais le sens est impondérable, invisible, compris seulement par l'être immatériel qui habite en nous.

Si le télégraphe est détraqué le sens ne sort plus ou sort mal avec des erreurs, des omissions, des fautes.

Si le télégraphe est refroidi il ne marche plus, vient on à le réchauffe il repart, alors le sens des dépèches reparait dans le texte.

L'âme est aussi une manifestation perpétuellement présente dans son organisme en bon état..

La manifestation est synchrone avec le bon fonctionnement de l'appareil, mais a une essence absolument différente.

Telle est la conclusion qui se dégage de cet ensemble d'expériences.

Conclusions générales.

Résumons maintenant les grandes lignes de l'étude des phénomènes cosmiques que nous venons de rappeler.

Tous les phénomènes sont ramenés à être fonction d'une seule variable, la distance qui sépare les éléments matériels qui constituent tous les corps connus.

L'éther enveloppe tous ces éléments et permet tous les mouvements oscillatoires et vibratoires des particules physiques et chimiques des corps.

Aux grandes distances on étudie les phénomènes astronomiques dans lesquels l'éther ne perturbe pas la loi de Newton.

Avec les points critiques en astronomie on précise au millimètre, l'ellipse d'une comète périodique ou d'une planète, et la trajectoire hyperbolique qui permet d'affirmer que l'astre est une voyageuse sans retour.

Aux distances petites, l'éther intervient et permet aux mouvements oscillatoires des particules de réprésenter le mode des phénomènes calorifiques et lumineux.

L'analyse spectrale nous renseigne sur les qualités essentielles des particules en mouvement, car par le spectre nous avons les longueurs d'ondes lumineuses provenant d'atomes ou de molécules ayant un certain poids et une attraction correspondant à leur volume et à leur masse.

Chaque corps a donc son spectre.

Le point de fusion des corps solides est équivalent au point critique en astronomie. Les molécules solides deviennent liquides en abandonnant le système rigide auquel elles appartenaient.

Les phénomènes de dilatation, de conductibilité, d'élasticité, etc., découlent tout naturellement de notre théorie.

Les changements d'état liquide en état de vapeur nous donnent un autre point critique pour la rupture de la molécule liquide et sa transformation en molécules ou atomes gazeux.

L'expérience démontre surabondamment la précision des distances ou des températures correspondant à ces points critiques des liquides.

Enfin nous sommes arrivés aux phénomènes chimiques qui prennent naissance par un effort négatif extérieur forçant les particules à pénétrer plus avant dans leur sphère d'attraction.

La molécule ou l'atome absorbe toujours de l'énergie pendant la première partie de cette contraction, l'atome passe par un état d'équilibre instable et tombe spontanément dans la position acquise après la réaction en produisant de l'énergie. Les réactions se partagent ainsi toutes en réactions exothermiques, produisant de la chaleur et en réaction endothermique, c'est à dire absorbant de la chaleur.

Les basses températures arrêtent toutes les réactions sans aucune exception.

Ce fait devient donc le critère spécial qui permet de distinguer un phénomène chimique d'un phénomène physique.

Le phénomène physique, chute d'une pierre, élasticité d'un ressort, couleur, etc., continue malgré les basses températures.

Les réactions chimiques ont leur point critique aussi marqué que les points critiques astronomiques et physiques. Les phénomènes vitaux sont perturbés mais pas supprimés par l'application des basses températures aux êtres vivants non abimés par la congélation.

Les phénomènes psychiques survivent aux basses températures lorsque les organismes résistent.

Ainsi en prenant la théorie de Newton et en lui appliquant les effets de l'attraction de la matière pour l'éther aux faibles distances on reconstitue une immense Astronomie moleculaire aussi précise, aussi exacte que l'astronomie astrale.

J'ai été l'humble élève des Newton, Kelvin, Helmholtz, Clerk-Maxwell, et je vous ai apporté, Messieurs et chers Collègues, le résultat de mes méditations sur le grand problème du monde dans lequel nous vivons, souffrons et mourons.

The Chairman said it would be agreed that this was not an occasion for a discussion; but a pleasant duty remained to be performed, especially as M. Pictet had travelled all the way from Berlin to be present on this occasion, namely, to propose a very hearty vote of thanks to him for his eloquent lecture.

Sir WILLIAM RAMSAY, K.C.B., F.R.S., seconded the vote of thanks. It had been most interesting to hear the Professor expound those fundamental ideas. If there had been time it would have been of interest to ask him if he could not extend his ideas not only to the attraction between element and element to form compounds, but to the attractions which formed the elements themselves. All would join in expressing the gratitude of the Society to the lecturer for his excellent exposition.

The resolution was carried and the meeting terminated.

EXAMINATION FRAUDS.

At Bow-street, on Saturday, the 13th inst., two cases were heard before Mr. Curtis Bennett, in which certain teachers were charged with improperly obtaining prizes in the Society's examinations.

The first case was that of JAMES T. HUGHES, aged thirty-five, of Birkbeck-avenue, Acton, who was summoned for obtaining a silver medal and £2 from the Royal Society of Arts by false pretences with intent to defraud; and the second was that of W. E. FRASER, of Ampton-street, Gray's Inn-road, who was summoned for obtaining £1 and a silver medal by similar means. Both defendants pleaded guilty.

Mr. BODKIN appeared to prosecute on behalf of the Director of Public Prosecutions, and Mr. TRAVERS HUMPHREYS appeared for the defence, while Mr. J. B. MATTHEWS held a watching brief for Mr. Clark, of Clark's College.

Mr. BODKIN, in opening the case, said it had been undertaken by the Public Prosecutor for the reason that it was of considerable importance to a large section of the community, and because of the standing of the Society. The defendant, James T. Hughes, had been for some time a tutor in arithmetical subjects at Clark's College in Chancery-lane. The Royal Society of Arts, which was the body primarily to suffer, had for some fifty years or more instituted under their charter a system of examinations in subjects connected with commercial life; and in connection with those examinations, and similar examinations of other bodies, there had grown up of recent years colleges or places where commercial education was mainly given, and amongst those colleges was the college to which the defendant had been attached. For the convenience of candidates the Society had localised their examinations at numerous places in the country; and occasionally, when there was a large number of students, the colleges were made local examination centres. A number of rules had been framed for the purpose of securing absolute propriety of conduct on the part of the candidates entering the examinations, and of ensuring that only real and genuine candidates should compete, and be entitled, if successful, to the prizes which the Society of Arts offered to those who attained the highest standard. One of the rules, most clearly expressed, was that no teacher in any institution where an examination centre existed would be admitted to examination at that centre, and another was that no person who had given instruction to any of the candidates in any subject of examination could serve as a superintendent of the examination, and no member or officer of a committee could be admitted to examination. The committee referred to was the local examination committee appointed for the particular examination held in accordance with the Society's rules. In connection with the examination of 1910, held at Clark's College, the usual committee was appointed, and amongst the number appeared the name of the defendant, "J. T. Hughes, Tutor, 15, Birkbeck-avenue, Acton." In addition to the names of the committee, who appeared largely to be persons interested in education, there was the name of the Secretary to the Examination Committee, "R. Sydney Fry, 1, 2 and 3, Chancery-lane."

From every candidate entering the examinations a nominal fee was required—a fee that barely covered the actual outlay necessitated by the examination—and those fees were collected at the local centres, and, together with the number of candidates in each particular subject, were forwarded to the Royal Society of Arts; and from that return the Society knew exactly the number of examination papers to send to the local centres. In 1910 the Society duly received the fees and particulars, and, in pursuance of the rules, forwarded to Mr. Fry, under a sealed cover, the exact number of examination papers required. When the candidates entered the room, persons had to be present to see to the maintenance of order, to distribute the papers, and at the proper time collect them from the students. On the day of the examination, April 12th, 1910, a Mr. Bird also acted as superintendent of the local centre at Clark's College, and the defendant Hughes and others representing the local committee were in the room. On that occasion it was evident that one or more students failed, either from illness or some other cause, to attend, and the defendant, in assisting in distributing the examination papers, helped himself to the paper of an absent candidate, took it into a room adjoining the examination room, and sat down and worked it out in the name of "Harold Nelson." According to the rules of the Society, at the end of the allotted time the examination papers had to be collected and initialled by the superintendent of the examination, and, if too late to post that evening, preserved until the next morning and then posted back to the Society. On the occasion in question, the superintendent apparently did not initial all the examination papers, as he was in a hurry to catch a train. He locked the papers up in his room for the night, and between that time and the next morning, when they were posted, the paper of "Harold Nelson" had been inserted amongst the

papers of the genuine competitors. In June the paper was awarded marks which earned for it a silver medal and a prize of £2. Under their rules the Society took an additional precaution. Before the prize or medal was given, the Society sent to the secretary of the local examination centre—in this case Mr. Fry—certain names of persons on whose papers the examiner had made awards, and amongst those names was that of "Harold Nelson." The document, which was signed by Sir Henry Wood, the Secretary of the Society of Arts, contained the following: "I shall be obliged to you if you will be so good as to let me know on the form attached whether the candidates at your examination centre whose names are given below are eligible for a medal or prize under the Society's regulations." And then followed the regulations in question, amongst which were: "No prize or medal in any subject will be awarded to anyone who is now acting, or has acted, as a teacher in that subject," and "No prize or medal in any subject will be awarded to any person over the age of 23 whose profession or occupation is connected with that subject, unless he or she has been a regular attendant at a class for instruction in the subject for examination during the twelve months preceding the date of examination." Then followed the entry: "Royal Society of Arts Examination, 1910, Clark's College; Name of Candidate, Harold Nelson; Age, 22; Subject, Arithmetic," and then, in the column for the reply, was written by Mr. Fry, "Eligible." After that certificate of eligibility was sent back to the Society, the results of the examination were printed and published, and the name of Harold Nelson appeared among the list of prize-winners, and in September a cheque for £2, signed by Sir Henry Wood on behalf of the Society, and payable to "H. Nelson," was sent to Mr. Fry, together with a silver medal, engraved "Harold Nelson, Advanced Examination, 1910, Arithmetic." If Mr. Fry, before he sent in the certificate of eligibility, had made the least inquiry, that certificate of eligibility would never have been sent. Mr. Fry handed to Hughes the cheque and the medal for presentation to "Harold Nelson," but, of course, they remained in the possession of the defendant. Since the summons had been issued, the medal, together with two sovereigns, had been returned to the Director of Public Prosecutions. The cheque received from the Society was endorsed by the defendant Hughes in the name of the payee. It was not for one moment suggested that the head of Clark's College was in the slightest degree cognisant of what had been going on; in fact, he was away in India when the examination took place, and it was not until the beginning of 1911 that he was apprised of what had been going on. Mr. Clark, the proprietor of the college in Chancery Lane, was also the proprietor of all the many branches set forth in his prospectus, and there was no question that Mr. Clark knew nothing whatever about a very large number of students entering such branches in different parts of London. But for the purpose—quite legitimately—of advertising the advantages of the college, a prospectus was published annually, and in that prospectus, under the heading of: "The Brilliant Display of Clark's College Students at the Last Examinations held, showing how the College made practically a clean sweep of the Highest Honours in the Commercial Examinations, and gained the Highest Awards open to Competition in these Examinations," was a list of "Prizes and Medals gained by our Students." This list included "H. Nelson, Medal and Prize £2, Arithmetic, Society of Arts, 1910." Counsel went on to point out that in the previous year—1909—under precisely the same conditions, the defendant, in the name of "Hugh James," worked and sent in another examination paper, for which he gained the first prize of £3 and a silver medal, and in the prospectus of Clark's College for 1909 the name of "H. James" appeared under the heading of: "The Brilliant Display of Clark's College Students." The prosecution was not undertaken because the Society of Arts felt any grievance at parting with silver medals or money; they felt that their examinations should be preserved absolutely inviolate so far as possible. Hitherto the regulations had been considered to be perfectly satisfactory, but it was possible they might have now to be reconsidered. If tutors were able to take part in the examinations, genuine competitors, whose future in life perhaps depended upon their getting particular diplomas, were placed at a great disadvantage and ousted from that chance. When the matter was discovered, the Society determined, on advice, that the only proper course open to them was to deal with the matter publicly; but they had no feeling in the smallest degree against the defendant individually, and no other desire than to show that people were not allowed, either by the rules of the examinations or by the law, to compete in examinations in a manner which was dishonest to other candidates. The proceedings were taken, in fact, to make it clear that it was a criminal offence, and, having gained that object, the Society respectfully asked the magistrate to deal with the case in such a way as not to make the future of the defendant harder than it otherwise would be. It was understood that Mr. Clark, as soon as he had been communicated with by the Royal Society of Arts, made full inquiries, and acted in the most drastic way, discharging the defendant there and then. Therefore the defendant, in one sense, had been punished, and the prosecution asked his Worship to give the fullest possible weight to that punishment in the decision he might come to, whatever it might be.

Mr. Travers Humphreys, on behalf of the defendant, admitted the seriousness of the offence, but pleaded that the appeal of the prosecution should be taken into consideration, and that the high character which the defendant had always borne, apart from the particular offence, should be allowed to have full weight. He admitted that the facts were exactly as stated by Mr. Bodkin, but

said the defendant had no intention of acting fraudulently. He had only in mind the certificate which anyone might obtain, and which he thought would assist his advancement in the department in which he was engaged. He was greatly surprised to receive a money prize and a medal in 1909. Having found how easily it could be done, he entered again in 1910, but on that occasion was not so successful, as he only obtained the second prize, the first being obtained by a student at the college. He asked the magistrate to take the view that the offence was not committed for the sake of the small monetary prize, but with the view—improper, of course—of securing his own advancement with Mr. Clark. Should the magistrate take a lenient view, there was a chance that Mr. Clark would take the defendant back into his employment, or assist him by such references—of course, apart from this matter—as would enable him to obtain some other employment in the future.

Mr. Curtis Bennett said the defendant had done not only, as counsel said, a very mean thing, but a very dishonourable thing. Defendant was quite old enough to appreciate the results of his actions and deeds, and he (his Worship) could not for a moment think he did not know from the very first—from the time he began to put his pen to paper—that he was doing something he had no right to do, and that, in obtaining something he was not entitled to obtain, he was depriving other people who had gone in for the examination from obtaining what was due to them. The prosecution had been very properly taken up by the Public Prosecutor, because if such things were allowed to go on, the value of the examinations would be at an end. The Public Prosecutor, through Mr. Bodkin, had pointed out in detail all the wrong which naturally followed from the course of conduct the defendant had adopted. It was probable that the mere value of the money prize was not so attractive to the defendant as the academic value of the honour of obtaining a medal and being in the list of prize-winners, and that seemed to explain the loss of the defendant's power of appreciating between right and wrong. The learned counsel for the prosecution had not only pointed that out, but had in exceptional terms asked that as lenient a course as possible should be taken in the case, and Mr. Humphreys had mentioned that if a lenient view were not taken, it would have the effect henceforth of depriving the defendant of the means of obtaining a living in the only profession in which he had been educated—namely, that of teaching. It had been further stated by learned counsel that justice having been done by bringing the defendant into Court, there might be a possibility of finding some employment for him by which he could earn a livelihood. Of recent years an enormous change had taken place in the awarding of punishment. Years ago, when he was first called to the Bar, sentences of penal servitude and of long terms of imprisonment were very common; but during the last twenty-five years there had grown up a system by which, instead of sentencing people to terms of imprisonment, an endeavour was made, if possible, to lead them to their own reformation while on probation. During the time he had been a magistrate he had, from the very commencement, on all occasions taken that course where he thought it was probable the result would be that the person charged would not again give way to temptation, but would lead an honest, honourable, and straightforward life. He had been assured by defendant's counsel that the defendant had determined, whatever sentence was passed upon him, he would never again be tempted to obtain that which he had no right to obtain, and would never again be guilty of a dishonourable action. It was but right that the public should know that such conduct could not, and would not, be tolerated, and that, should it unfortunately occur again, the present case would be remembered, and the punishment would probably not be the same as he was about to award the defendant. Taking all those facts into consideration, he should order the defendant to find two sureties in £100 each, and to enter into his own recognisances of £200 to come up for judgment if called upon within the next two years. If the defendant's actions in future were what they should be, he would hear no more of the matter, but should he give way again, he would have to appear before the Court, when it would be his (the magistrate's) duty to pass sentence upon him.

The recognisances were entered into at once.

The second case was that of William Edward Stuart Fraser, Tutor, of Ampton-street, Gray's Inn-road, who pleaded guilty to a charge of obtaining a cheque of £1 and a silver medal from the Royal Society of Arts by false pretences in the year 1909.

Mr. Bodkin outlined the case, which was of a somewhat similar character to the last. The defendant was employed at Clark's College, in Chancery-lane, as a tutor in arithmetic, and was also a member of the local examination committee, and sent in an examination paper under the name of "W. E. Stuart," and as "W. E. Stuart" was advertised under the heading of "The Brilliant Display of Clark's College Students during 1909." Counsel thought the cases of both Hughes and Fraser showed there was very gross carelessness at the college, seeing that certificates of eligibility were issued with regard to fictitious students, and names published in the prospectus of the college of persons who were never students at all. He did not wish to make the slightest suggestion with regard to Mr. Clark himself, who necessarily had to leave, in such a very large business, the details to heads of departments. Mr. Clark had taken the very proper course of cancelling the inaccuracies in the prospectuses for 1909 and 1910, but the names of "Hughes" and "Fraser" still

appeared in connection with other examinations in the prospectus for 1911, and it was quite wrong to continue to publish the names of two paid tutors of the college as having gained successes as students. He hoped that would be remedied. Mr. Bodkin made the same appeal for leniency on behalf of the present defendant as he had made on behalf of the defendant Hughes.

Mr. TRAVERS HUMPHREYS said when the defendant entered in 1909 for the examination, he had no idea that he would obtain anything more than a certificate, and it was to his credit that, having done it in that year, he did not take the opportunity of doing it again in 1910.

Mr. CURTIS BENNETT said the defendant was in Court, and heard the decision in the last case, and he need not repeat what he had then said. The sentence would be of a similar character to that which had been passed upon Hughes, but having regard to the somewhat lower position the defendant occupied, he should be content to bind him over for twelve months on the defendant's own recognisances in the sum of £50 and one surety in £50, or two in £25. Referring to Mr. Bodkin's remarks with reference to Clark's College, he desired to say he entirely agreed with those observations. From the way in which Mr. Clark had behaved in the matter, he felt sure he would see at once that all reference to the success of students so far as the two defendants were concerned would be deleted from advertisements appearing in the papers.

The recognisances were entered into.

Mr. CURTIS BENNETT said he understood the money had been returned, and he would make an order that the medals should be returned also.

Mr. J. B. MATTHEWS asked permission to make a statement on behalf of Clark's College. On Mr. Clark recognising the deplorable negligence on the part of one or two officials, they were dealt with very promptly by being removed from their positions, and the two defendants were immediately discharged. The college at present had over 6,000 students, and naturally there was opportunity for irregularities to occur without the personal knowledge of the head of the college, who had to trust his subordinates. He desired to assure the public that there would be nothing lacking on the part of the college in future to see that no opportunities of the kind occurred again. With regard to the prospectuses, they would be at once corrected, so that no false impressions might be given, Mr. Clark being very insistent that nothing should be put in the prospectuses which was in the slightest degree misleading.

Mr. BODKIN believed the undertaking would be carried out in the thorough spirit in which it was given, but said that, should there be any failure—which he did not believe would occur—the Royal Society of Arts would have very carefully to consider whether Clark's College could remain a local centre for examinations in the future.

THE RUSSIAN TIMBER INDUSTRY.

The Russian Empire occupies the first place among the nations of the world in the extent of its timber resources, the value and quality of two-thirds of which are practically unknown. The total area of the Russian Empire is 8,647,657 square miles, or about one-seventh of the entire land area of the globe, and 39 per cent. of the surface of the Empire is under forests. Those in European Russia cover an area of 474,000,000 acres; Finland, 50,500,000; Poland, 6,700,000; Caucasus, 18,600,000; total, 549,800,000. In the Ural provinces forests cover 70 per cent. of the area; in the northern provinces 68 per cent., and in the four lake provinces 57 per cent. The Government owns 65 per cent. of these forests, possessing in European Russia, 285,598,941 acres; Caucasus, 12,826,387; Asiatic Russia, 360,519,435; Amur region, 288,742,000; total, 947,686,763. Twenty-three per cent. of the forests belong to the landed proprietors, and 9 per cent. to the peasantry. It is estimated that in western Siberia alone there are 465,000,000 acres in virgin forest, and eastern Siberia, although not quite so rich in timber, has sufficient forests for the world's supply of timber for years to come. According to the American Consul at Moscow, the largest timber districts in European Russia are in the north. The four Governments of Olonetz, Archangel, Vologda and Viatka, comprising a total area of 650,000 square miles, are almost entirely covered with timber, but the greater part has never been explored by civilised man, though expeditions are now being formed for the purpose of investigating the immense resources of the country. The State forests, during a recent year, yielded 1,286,560,000 cubic feet of lumber, the Department of Forestry realising in round numbers for the sale of timber, rent of lands, etc., £6,500,000. The expenditure, including £160,000 for cutting trees and sawing logs, amounted to £1,400,000, thus leaving a profit to the State of £5,100,000. It is stated officially that the reafforestation of State lands provides for more than the amount cut from the forests each year. The above figures do not include the timber lands owned by private parties in European Russia. They are divided as follows:—Imperial appanages, 14,274,500 acres; private landowners, 151,072,000; peasants, 29,210,000; joint-stock companies, factories, works, churches, etc., 6,853,500 acres. The Russian timber industry comprises 1,428 factories, saw-mills, planing establishments, wooden-box factories, piano factories, etc., the number of hands employed being 80,000, and the value of the annual output £16,000,000. This industry is one of the greatest in the Empire, and offers many possibilities, which should not be

neglected by manufacturers, of requisite machinery. In a recent year Russia imported saw-mill machinery and wood-working machinery to the value of £17,500 and £56,000 respectively. Timber ranks second in the exports of Russia, preceded only by grain.

THE MANUFACTURE OF POTATO-SPIRIT IN GERMANY.

The immense production of potato-alcohol in Germany is due largely to the agricultural advantage of the potato crop for rotation purposes, and the efforts of the Government to favour the business by the remission of taxes. Over 77 per cent. of the total production of German alcohol is obtained from potatoes, but only a comparatively small portion is sold in the form of beverages, for the reason that other kinds of alcohol are better adapted to the manufacture of liqueurs and brandies. The alcohols of wine, cider and cherries possess an agreeable aroma, whereas all alcohols produced from beets, grains, molasses and potatoes must be rectified before they are available for consumption, in order to free them of their unpleasant natural taste. As to potatoes, the resultant alcohol possesses an oily flavour, which would be particularly unpleasant if not eradicated by rectification. Potatoes intended for conversion into alcohol are first provided in the average proportion of 900 kilogrammes (1,984 lbs.) of raw material for the production of 26 gallons of 100-degree theoretical spirit. According to the American Consul at Hamburg, the potatoes are first washed, and then steam-cooked for the reduction of the starch to a state easily convertible into sugar. This steaming is commonly performed in a conical device, in which the tubers are boiled until soft. This soft material is next pressed through a grating provided with sharp edges, into the mashing-tub. As this first mashing is insufficient, the material is more completely disintegrated in the mashing-tub under a cylinder, or in a mill placed between the cooking machine and the mashing-tub. The malt is generally added in a crushed form, and further crushed into the potatoes. The fermented diastase in the malt converts the potato-starch into sugar in about thirty minutes, the most favourable temperature for this conversion being 130° F. Formerly a temperature of 150° F. was deemed necessary in order to destroy the schizomycetes inimical to the process of fermentation, but this destruction is now secured by adding fluoride of sodium, or fluor acid, in small quantities, to the ferment. The sugared mass is now cooled down by water and air, after which artificial yeast is added. This addition produces a fermentation in which the sugar is converted into alcohol in the wooden mash-tub. These tubs are made of oak or fir wood. As the manufacture of alcohol in Germany is taxed according to the space occupied for mashing purposes, the mash is made as thick as possible. At the present time there are about 6,000 small and 40 industrial distilleries in Germany. The crop of potatoes in Germany in 1909 amounted to 47 million tons, which was exceeded only by the crops of 1901 and 1905, 49 million tons and 48 million tons respectively, during the last eleven years. The production of alcohol from potatoes in Germany in 1908-09 amounted to 75 million gallons.

HOME INDUSTRIES.

Population in Scotland.—It is only natural that the figures of the Scottish Census have caused not only surprise but something not unlike alarm. The estimate of population to be found in the Statistical Abstract of the United Kingdom gives Scotland a population in 1911 of 4,929,251. According to the preliminary returns, the population given to Scotland by the Census is 4,759,521. Instead of an estimated increase of 400,000 in the decade, the actual increase is only 287,418. The gain in the decade represents an advance of 6·4 per cent., or a little more than one-half per cent. per annum. This is the lowest percentage, save one, recorded for more than a generation. Until the returns have been analysed the distribution of the increase cannot be precisely stated, but enough is known to make it safe to say that those from the rural districts are the most disappointing. In some rural districts there has been actual depopulation, while the urban figures—after all allowance is made for the alteration of town boundaries, and for the movement outwards so characteristic of every great town—do not show the increase that was expected. The explanation of this general decline in the percentage of increase, and actual decrease in some county districts, is not far to seek. The rural districts have suffered from the migration to the towns which has been going on for many years, and still more by emigration to other countries. In the last ten years there has been a great exodus from Scotland. In the United Kingdom we have now active Government official agencies for drawing population from our shores, which are becoming very efficient in suggesting to the working population that the United Kingdom is a poor place for lads of spirit. The Dominion Government is spending enormous sums in what may be called the literature of emigration, and the Commonwealth is beginning to follow suit. In these circumstances it is not strange that emigration grows apace, more especially when it is remembered that although the wealth of the United Kingdom has increased enormously during the past decade, the wages of workmen have not only not advanced but show a slight decline. The distribution of the increased wealth is extremely uneven, and never was the Biblical saying that "unto him who hath shall be given" better illustrated than in these days. So far as Scotland is concerned, the emigration is largely made up of peasants, of men we would fain keep in the country. But lamentable as it is, this emigration will almost certainly continue, and may well be accelerated, unless by some means or other the home prospects of the countryman are

improved. The magic of property, however small the holding, may suffice to keep him with us; it is doubtful whether anything less potent will do so. The facilities of travel, the spread of education, the emigration agencies, all tend to make the peasant, and in a lesser but still considerable degree the townsman, dissatisfied with his lot in the old country. Scotland has not reached the stage where population has become stagnant, but if the present tendency continues it may soon do so. As it is the population still grows, but year by year the countryside is becoming more depopulated. The big towns swell, but the land under cultivation shrinks. That is not a healthy state of things, and if no remedy is found for it the natural well-being must be greatly affected.

The Insurance Bill.—It may be said without much fear of contradiction that it would be difficult to name any Bill of first-class importance that has been received by the House of Commons with the general welcome and commendation extended to the State Insurance Bill. But without expressing any opinion upon the general merits of the Bill, it is to be feared that if it becomes an Act it will affect many persons in a way not contemplated or desired by its authors. Take, for example, that section of the Bill which deals with a very humble but numerous section of the community, the domestic servants. The proposal of the Bill is that each servant shall be required to affix three stamps to a card each week, and the employer another three. That gives the servant in case of sickness free doctoring and medicine, and an allowance of 7*s.* 6*d.* a week for the first three months and 5*s.* a week for the next three months. But, assuming that this is fair return for the money, and it is by no means certain that better terms might not be got from existing agencies, is there not a real danger that many employers will get rid of their servants rather than pay the 13*s.* per annum? It must be remembered that in an immense number of households it is a hard struggle to keep a servant, it is only possible to keep one to whom low wages are paid, and the additional 13*s.* may well turn the balance against keeping any at all. When the Workmen's Compensation Bill was before Parliament, and it was decided to include domestic servants, it was believed by the framers of the Bill that they were helping one of the most helpless of the classes. The contrary has happened. Although it is possible to insure against risk for a very small sum, two or three shillings, and this insurance relieves the assured of all responsibility and trouble, it has been found that in a large number of cases mistresses of the smaller sort—and they constitute the great majority of the households of the kingdom—have either dispensed with the charwoman and the general servant altogether, or refused to employ any person not in the prime of life. That has worked great hardship amongst women particularly requiring assistance. But now that these same mistresses are asked to pay a weekly sum which, to many of them, may mean a good deal, and also to be at the trouble of pasting stamps on every week, it is more than likely they will prefer to be without a servant, and once more an Act intended for their benefit will actually injure some of the more helpless of those it was intended to assist. That may be an inevitable consequence of any system of State insurance that the wit of man can devise, but whether or not, it is a difficulty to be considered. It may well be doubted, too, whether the proposals of the Bill as they affect the doctors who are to attend those to be benefited by the Act can be worked without grave injustice, and in some cases positive ruin, to medical men whose practice is practically confined to what are called the working-classes. Fortunately, there is no reason to suppose that the authors of the Bill will be unwilling to amend it upon cause shown. On the contrary, the Chancellor of the Exchequer has invited criticism, and promises to regard it with an open mind.

Malingering.—Among the less desirable consequences of the Bill, should it become law, malingering is likely to have a prominent place. And here, it is to be feared, the danger will not only be real but formidable. It is well known that the Workmen's Compensation Acts have greatly encouraged malingering. Men who in the days prior to these Acts met with accidents, sought to get well and to work again as quickly as possible, since anything like long illness meant calamity to the home. But the incentive to recovery will be greatly weakened if a man is to be able to rely upon 10*s.* a week for three months, and 5*s.* for another three months. These allowances, though modest enough in themselves, may be sufficient to lead to a serious spread of malingering. It may be that the Government will be able to devise some scheme of supervision which will prevent anything like serious imposition, but it is not easy to see how it is to be done. The Bill threatens something like a return to the state of things disclosed by the Poor Law Commission of 1834, and that is not a prospect that can be viewed with anything approaching equanimity. Every clause of the Bill calls for exhaustive discussion, but none more than the clauses which threaten to encourage the loafer.

Produce of Crops.—The Returns of Produce of Crops in Great Britain, just published by the Board of Agriculture and Fisheries, show that in the case of every crop the average yield for Great Britain was higher, and in some cases considerably higher, in 1901-10 than in 1891-1900. To England, considered separately, the same observation applies, and except for potatoes in Wales, and barley in Scotland, it would apply to those countries also. As Mr. Rew points out, increased yields per acre as between one period and another may be regarded as an indication of more favourable seasons, and as representing larger gross returns to the cultivators of the soil. They do not necessarily connote increased total production from

the land, unless the area cultivated remains at least equal in extent. The average annual production of wheat in Great Britain in 1901-10 was over half a million (547,042) quarters less than in 1891-1900, while that of barley was a million quarters less. The production of peas was 65,000 quarters less per annum, and of turnips and swedes more than a million tons less, while the output of hops fell from an average of 469,000 cwts. in 1891-1900 to 397,000 cwts. in 1901-10. On the other hand, the annual production of oats increased by 700,000 quarters, of beans by 154,000 quarters, of potatoes by 338,000 tons, of mangolds by $2\frac{1}{4}$ million tons, and of hay (of all kinds) by nearly a million tons. The home production of wheat has declined even more markedly in relation to demand than is indicated by the actual figures of diminished crops. In the first decade of the present century the gross production of wheat—which is, of course, not all brought into the market—in Great Britain was equal to 1·37 bushels per head of the population. In the preceding decade the gross production was equal to 1·66 bushels per head. For the six years ending with 1890—the official returns of crops do not go further back than 1884—the total wheat crop was equivalent to 2·26 bushels per head of the population at that time. The home supply of potatoes appears to have kept pace more nearly with the demand. The total hypothetical value of the corn crops in 1910—£31,550,000—was £4,600,000 less than in 1909, but a reduction, the extent of which cannot be estimated, must be made from the total value of the 1909 crops, on account of inferior and unmarketable corn. The value of the potato crop—£11,127,000—was £1,200,000 more in 1910, on account of the rise in prices, while the additional bulk of the hay crops was of an estimated value of £3,100,000. The total value of clover, etc., hay in 1910 was £13,710,000, as against £12,478,000 in 1909, and of meadow hay, £22,508,000, as compared with £20,643,000 in the preceding year.

CORRESPONDENCE.

IMPROVEMENTS IN THE TRANSPORT AND DISTRIBUTION OF GOODS IN LONDON.

I am sorry that I had to leave before the discussion on Mr. Gattie's paper on the 5th inst. concluded.

I venture to think Mr. Gattie has not covered the points I raised. Any modern improvements that save time and relieve congestion should be heartily welcomed, but, as I understand the matter, "The New Transport Company, Ltd." look to continuous working throughout the day as one of the essentials of their scheme, and it would seem that their figures need some modification.

It may be taken for granted that the bulk of orders coming by post arrive by the early morning deliveries. These orders are dealt with in the course of the day, and are ready towards evening for collection in order to be sent to various parts. Similarly, in the provinces orders executed during the day are put on rail for the evening trains to London, and arrive here in the early morning. After being dealt with by the Clearing House, it is not clear how these trains could immediately be reloaded, as the bulk of the outgoing traffic would not be ready until the late afternoon.

Every business house is desirous of receiving goods, if possible, by 9 a.m., and it would, therefore, appear that, although the provision for rapid handling in the Clearing House is on a fairly extensive scale, it would need still further extension to provide for this. If it requires five hours to dispose of the two hundred and ninety trains, it is obvious that quite a large proportion of the packages would not be delivered at their destination until lunch-time, and from the standpoint of congestion in the streets it is also desirable that all heavy wagons should be unloaded not later than 9 a.m.

With regard to documentation, Mr. Gattie does not clear up the point I raised. I quite agree that electric carriers can act—with human intelligence at each end—with greater accuracy than the "man with a truck," but I do not suppose even Mr. Gattie would claim that they can make out documents. The Hollerith tabulator, which does such marvellous work, does not read the invoices and punch the cards from which results are summarised.

The cases I have in mind are those where, after the documents are checked from a container, the goods are wheeled round, say, from the G.N. to the L.B. & S.C. Railway section of the building. In such cases a document can be handed to the man who wheels a truck, and he in turn can hand the same to the receiving man and obtain his initial in the book provided. The electric conveyor cannot do this, and as a large number of packages in transit would be going to small towns and villages, where present arrangements would have to continue, it would be necessary that the documentation should be in the usual form, and not, say, in the form of cards punched for electrical contacts which would be unintelligible at such places.

With regard to the distribution of goods, in order to accomplish rapid delivery in the early morning, and speedy collection in a limited time towards evening, I am inclined to think that the number of wagons mentioned by Mr. Gattie would have to be considerably augmented. He appears to be rather regarding the total volume of business on the assumption that he can keep a more or less even load throughout the day, which, for reasons given earlier, seems quite out of the question.

I hope that Mr. Gattie will see his way to explain clearly and fully how he proposes to get over the difficulties raised, as doubtless there are many others besides myself who found the explanation lacking in his paper.

S. CHAPMAN.

In reply to Mr. S. Chapman, reference to the working time-tables of the various railway companies shows that goods trains arrive in London in varying numbers all through the day and night. They are arranged to fit in with shunting requirements, and much valuable time is wasted as a consequence of this shunting. There are also hundreds of goods trains, plying between London's seventy-four goods stations, which would be rendered quite unnecessary under Clearing House conditions. But even under existing conditions Mr. Chapman's difficulties are hard to appreciate: e.g., the London and South-Eastern Railway have thirty goods trains coming into London between 8.20 p.m. and 2.40 a.m. By what black magic would the Clearing House be disabled from unloading and reloading those thirty trains?

What Mr. Chapman says, in effect, is this: "The Clearing House is all very well, but suppose a time-table got in the way?"

The question is reminiscent, and the answer to it is: "So much the worse for the time-table."

With regard to Mr. Chapman's question of documentation: On a labelled bale of goods being received at the Clearing House it would be removed from the container in which it arrived and checked off against the list of the contents of that container. It would be put on to a tray and sent to the necessary bay. On arriving at that bay it would be weighed, charged and entered, and put into the container provided to take it to its destination.

It is sufficiently obvious that any documentation possible in a goods station must be equally possible in a Clearing House, but, as indicated above, Clearing House documentation would be very simple. Each item, or group of items, would be booked *in*, and booked *out*, in exactly the same way as is practised in the Bankers' Clearing House.

Let us compare the simplicity of the Bankers' Clearing House method with that of the railway companies.

A case of goods weighing a little over one hundredweight was despatched from Tottenham to Bristol. It was collected at 12 a.m. on Thursday and taken to Tottenham Hale, thence to Bishopsgate, thence to Birmingham, thence to Derby, and thence to Bristol, where it arrived one week after the date of despatch. Here the consignee refused to accept delivery—a second consignment having been "expressed" by G.W.R. passenger train. Fifteen days after, the G.E.R. wrote to the consignor that the goods were lying at his risk at Derby, and demurrage would be charged. Another week elapsed, and after further correspondence the G.E.R. returned the goods to the consignor, made no charge whatever, and paid 15*s*. damages.

The advantage of the Clearing House system is, that it requires a coincidence of errors for a mistake to go through, and by its application to railway work such instances as the above would be much reduced in number.

A. W. Gattie.

NOTES ON BOOKS.

Old Clocks and Watches and their Makers. By F. J. Britten. Third Edition. London: B. T. Batsford. 15*s*. net.

In the third edition of his well-known work, Mr. Britten has added a considerable amount of fresh matter and over a hundred further illustrations, and the book is now a very complete historical and descriptive account of the different styles of clocks and watches of the past. Starting with a brief account of early time recorders—sundials, wick and lamp time-keepers, sand-glasses, etc.—the author passes on to weight-clocks, portable time-keepers, and pocket-watches. An interesting chapter is devoted to short sketches of the lives and achievements of the most famous makers, from Tompion, "the Father of English Horology," to the end of the eighteenth century. The next section deals with French clocks and cases, and this is followed by a chapter on English domestic clocks, including a very fully illustrated portion on "grandfathers." The last chapter includes a series of hall-marks, which is very useful as a guide in determining dates. An appendix contains the names and some biographical details of 11,000 former makers. It is interesting to note that thirteen of these received medals or other rewards from the Society of Arts, for various improvements in clocks and watches. The book is profusely illustrated throughout, and will still further enhance Mr. Britten's reputation as an authority on the subject of horology.

GENERAL NOTES.

Chinese Tea Exports.—The total quantity of tea exported from China in 1909 was 199,792,400 pounds, a decrease of over ten million pounds as compared with 1908. This reduction was due principally to a decreased demand for common black teas due, according to the American Consul at Shanghai, to the abundant supply from India and Ceylon of the low grades used in cheap mixtures. Steps are being taken to regain in some measure the trade in Ning-chow teas. The Viceroy and Governor of Kiangsi has been asked to supply the growers of these teas with fertilizers, as their decline is largely due to farmers having neglected to clean the ground, turn it over and fertilize it. In the Keeman district, where strict attention has been paid to these matters, the teas produced have attained great popularity, and the production, which amounted to 20,000 half-chests a few years ago, reached 95,000 half-chests in 1909. Owing to the absence of suitable storage facilities for the crop, especially that of the Hankow variety, which is stored in junks and subjected to all kinds of weather, etc., the Ministry has been petitioned to build a go-down capable of holding at least 200,000 half-chests of tea.

German Fresh-water Pearl Fisheries.—The once famous fresh-water pearl fisheries in the river known as the White Elster, in the Plauen district of Saxony, have steadily declined in importance. Although the fishing is carried on under the supervision of Government inspectors, and every care is taken to foster the growth of a variety of pearls well known on the market, the yield has so dwindled that during the past year only six good pearls and seventeen of second quality were found. This is a contrast to preceding years, when large quantities were obtained during the fishing season. From 1861 to 1900 nearly 4,600 pearls of all grades were found. Some of the best years were during the middle of the seventeenth century, but owing chiefly to the increase of factories along the banks of the stream, contaminating the water, as well as to the destructive agency of floods and ice-floes, the historic pearl fisheries are now threatened with extinction.

Commercial Schools in St. Petersburg.—There are in all twelve commercial schools in St. Petersburg, though none of these is strictly limited to commercial branches. General instruction is given to students from the age of nine to nineteen, and special instruction from sixteen to twenty-one. It is the special instruction only that contains commercial branches. For the two leading schools, for example, the curriculum in the special or commercial instruction is as follows:—Book-keeping and commercial correspondence, technical chemistry, political economy, jurisprudence, commercial law and law proceedings, history of commerce, commercial geography and statistics, commercial arithmetic, and the Russian, French, German and English languages. In the Imperial school the children of Russian merchants are admitted without pay. All other students, either Russian or foreign, pay £20 per annum if non-resident, and £45 if resident. In the Petrovski school all classes pay from £15 to £17 per annum, the lower scale being in the case of children of local merchants. An examination is required for admission to both schools, to be conducted in the Russian language. There are at least five other commercial schools in the city conducted by persons receiving authorisation to do so from the Minister of Public Works, where, in addition to the foregoing curriculum, the adult pupils, male and female, are taught stenography and typewriting.

International Congress of Applied Chemistry.—The Eighth International Congress of Applied Chemistry will be opened by the President of the United States, at Washington, on September 4th, 1912; the other meetings, business and scientific, will be held in New York from September 6th–13th. The Congress will be divided into twenty-three sections and sub-sections, including every branch of Applied Chemistry. Papers for presentation or publication should be in the hands of the American Committee on or before July 1st, 1912.

Uruguayan Ostrich Feathers.—The feather industry is of considerable importance in Uruguay, and the ostrich is one of the nation's valuable assets. The native ostrich or "nandu" of Uruguay and Argentina resembles the African bird in a general way, but is smaller, of a mixed grey colour, and has three toes, whereas the larger species has only two. A still smaller species is found in Patagonia, and seems to range much farther north, the males each having five or six females with them, generally keeping together in flocks of fifteen to thirty. These are found roaming throughout the open country of Uruguay. The average height is five feet, and the weight 80 to 100 lbs. each. Several females lay their eggs in one nest, which is merely a hole found anywhere in the ground. The eggs weigh about two pounds each, and are sat upon and hatched in forty days solely by the male. To secure the feathers, which have become an important article of export, the birds, at the time the plumage is full, are driven into previously-arranged nets and their feathers pulled out. The majority of the feathers are very fine, sometimes equalling, and even excelling, the African in quality, but smaller. This is remedied by joining three feathers lengthways. Some years ago there were nearly 100,000 native ostriches in Uruguay, but this number has recently fallen off, owing to the migration of the ostriches to Argentina.

The Production of New Zealand Flax.—Phormium tenax, or New Zealand flax, is indigenous to the country, and is found growing in low or swampy ground in all parts of the dominion. The plant grows from five to ten feet high, and it takes eight or nine tons of leaves to produce one ton of fibre. The method employed for cleaning and stripping the leaves is as follows:—The leaves are first put through the stripper to bruise the fibre and prepare it for washing, which is immediately done. This removes much of the woody matter. Then the material is spread on the grass to bleach, after which it is put through the scutcher, which cleans it and removes the coarse and broken parts called tow. The flax is then put into hanks and baled, when it becomes ready for market. A new machine has just come on the market, which automatically strips and washes the fibre in one operation.

Sericulture in the Province of Como.—A small quantity of selected "seed" (silkworms' eggs) has been placed, as an experiment, at the disposal of the Prefect of Como, for free distribution amongst the sericulturists of the province this season. The "seed," which is of three kinds, viz., Chinese and indigenous producing cocoons of yellow colour, and also a cross-bred variety, was obtained from the moths of silkworms reared last season on leaves that had been treated with a solution of chloride of silver. This solution is used as a remedy for the disease to the mulberry tree so prevalent in Italy.

MEETINGS OF THE SOCIETY.

ORDINARY MEETING.

Wednesday evening, at 8 o'clock :—

MAY 24.—FRANK M. ANDREWS, "Architecture in America." Sir ASTON WEBB, C.B., R.A., F.R.I.B.A., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 o'clock :—

MAY 25.—W. R. H. MERK, C.S.I., LL.D., "The North-West Frontier Province of India." The Right Hon. the EARL OF MINTO, K.G., G.C.S.I., G.C.M.G., G.C.I.E., will preside.

CANTOR LECTURE.

Monday Evening, at 8 o'clock :—

ALFRED E. H. TUTTON, M.A., D.Sc., F.R.S., "Rock Crystal : its Structure and Uses." Four Lectures.

Syllabus.

LECTURE IV.—MAY 22.—*Scientific and Industrial Uses of Rock Crystal.* Its Thermal and Electric Properties, and its Transparency to Ultra-violet Rays—The Construction of Prisms and Lenses (including spectacles) of Rock Crystal, and their Advantages over Glass—The Use of Quartz for Balance Weights and in connection with the Interferometer—The Artistic Use of Quartz for the Carving of Vases and other Objects—Destruction of the Crystalline Structure by Fusion, and the Uses of Fused Silica in Fibres and Scientific Apparatus.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 22...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Dr. A. E. H. Tutton, "Rock Crystal : its Structure and Uses." (Lecture IV.)

Chemical Industries Exhibition, Agricultural Hall, Islington, N., 4.30 p.m. Mr. T. Tyrer, "Industrial Spirit." 8 p.m. Mr. L. Gaster, "Progress in Modern Illuminants and their Industrial Application."

Geographical, Burlington-gardens, W., 3 p.m. Anniversary Meeting.

British Architects, 9, Conduit-street, W., 8 p.m. Mr. R. Anning Bell, "Painted Relief."

Victoria Institute, 1, Adelphi-terrace House, W.C., 4.30 p.m. Rev. Canon J. A. MacCulloch, "The Descent into Hades : a Study in Comparative Theology."

TUESDAY, MAY 23...Faraday Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. 1. Dr. Arthur L. Day, "Recent Advances in Gas Thermometry." 2. Dr. J. A. Harker, "The High Temperature Equipment at the National Physical Laboratory." 3. Mr. H. C. Greenwood, "The Boiling-points of Metals." 4. Mr. A. Blackie, "The Behaviour of Silica at High Temperatures." 5. Communications will be read from Professor Bodenstein (Hanover) "On the Maintenance of Constant High Temperatures," and from M. Féry (Paris), on "Stellar Pyrometry."

Royal Institution, Albemarle-street, W., 3 p.m. Professor F. W. Mott, "The Brain and the Hand." (Lecture II.)

Chemical Industries Exhibition, Agricultural Hall, Islington, N., 8 p.m. Mr. R. W. Sindall, "Paper and Pulp."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Dr. J. Stuart Thomson, "The Alcyonaria of the Cape of Good Hope and Natal." 2. Dr. H. W. Marett Tims and Mr. A. Hopewell Smith, "Tooth-Germs in a Kangaroo." 3. Dr. R. Broom, "On the Structure of the Skull in Cynodont Reptiles." 4. Rev. A. Miles Moss, "On the Sphingidæ of Peru." With a Preface by Dr. Karl Jordan.

WEDNESDAY, MAY 24...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Frank M. Andrews, "Architecture in America."

Geological, Burlington House, W., 8 p.m.

Chemical Industries Exhibition, Agricultural Hall, Islington, N., 8 p.m. Mr. C. Harrap, "Chemistry of Lithography."

Concrete Institute, 296, Vauxhall-bridge-road, S.W., 5.45 p.m. Mr. R. W. Vawdrey, "Reinforced-Concrete." (Lecture V.)

Mining and Metallurgy, at the Geological Society, Burlington House, W., 8 p.m.

THURSDAY, MAY 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. W. R. H. Merk, "The North-West Province of India."

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 3 p.m. Anniversary Meeting.

Chemical Industries Exhibition, Agricultural Hall, Islington, N., 8 p.m. Mr. W. J. Dibdin, "Sewage Disposal."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. N. Shaw, "Air and the Flying-Machine." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Dr. A. Abrahams, "High-Speed Photography."

FRIDAY, MAY 26...Municipal and County Engineers (Scottish District Meeting), Govan and Loch Arklet, 12 noon. 1. Discussion on Paper by Mr. F. G. Holmes, "The Main Drainage and other Municipal Works of Govan." 2. Discussion on Paper by Mr. W. C. Easton, "The Treatment of Govan Sewage." 3. Inspection of Burgh Works, etc.

Royal Institution, Albemarle-street W., 9 p.m. Professor Gilbert Murray, "The Greek Chorus as an Art Form."

Chemical Industries Exhibition, Agricultural Hall, Islington, N., 8 p.m. Mr. Noel Heaton, "Artificial Production of Precious Stones."

SATURDAY, MAY 27...Municipal and County Engineers (Metropolitan District Meeting), Town Hall, Wellington-street, Woolwich, 12 noon. 1. Mr. J. Rush Dixon, "Woolwich and some of its Works since 1905." 2. Mr. E. H. Tabor, "Description of the Woolwich Footway Tunnel under Thames." 3. Visits to Council Works, etc.

Chemical Industries Exhibition, Agricultural Hall, Islington, N., 8 p.m. Dr. F. M. Perkin, "Applications of Electro-Chemistry and Electro Metallurgy."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. W. P. Pycraft, "Phases of Bird Life : Migration." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,053. VOL. LIX.

FRIDAY, MAY 26, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

CANTOR LECTURE.

On Monday Evening, May 22nd, Dr. ALFRED E. H. TUTTON, M.A., F.R.S., delivered the fourth and last lecture of his course on "Rock Crystal: its Structure and Uses."

On the motion of the Chairman, Sir WILLIAM H. WHITE, K.C.B., F.R.S., a vote of thanks was accorded to Dr. Tutton for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

INDIAN SECTION.

THURSDAY AFTERNOON, MAY 25TH, The Right Hon. The EARL OF MINTO, K.G., G.C.S.I., G.C.M.G., G.C.I.E., in the chair. A paper on "The North-West Frontier Province of India" was read by W. R. H. MERK, C.S.I., LL.D.

The paper and discussion will be published in a subsequent number of the *Journal.*

APPOINTMENT OF DELEGATES.

The Council have appointed their Chairman, Sir JOHN CAMERON LAMB, C.B., C.M.G., to represent the Society at the celebration of the Five Hundredth Anniversary of the Foundation of the University of St. Andrews, in September, 1911.

Sir BOVERTON REDWOOD, D.Sc., F.R.S.E., has been appointed to represent the Society at a joint meeting to be held under the auspices of the Society of Chemical Industry, for the purpose of securing a full attendance of British Chemists and a good supply of original papers at the Eighth Annual Congress of Applied Chemistry in Washington and New York in September, 1912.

CONVERSAZIONE.

The Society's Conversazione will be held, by permission of the Trustees of the British Museum, in the Galleries of the Natural History Museum, South Kensington, on Tuesday Evening, May 30th, from 9 p.m. to 12.

The Reception, by Sir JOHN CAMERON LAMB, C.B., C.M.G., Chairman, and the other Members of the Council, will be held in the Central Hall from 9 p.m. to 10.

A Selection of Music will be performed by the Band of H.M. Royal Artillery, in the Central Hall, commencing at 9 o'clock.

A Vocal and Instrumental Concert will be given in the Fish Gallery and a Miscellaneous Entertainment in the Shell Gallery, under the direction of Mr. PATRICK KIRWAN, commencing at 9.30 p.m.

The following portions of the Museum will be open:—

The Central Hall, containing cases of specimens illustrating Mimicry; Adaptation of Colour to surrounding conditions; Protective Resemblance; etc. Also specimens illustrating the Food of Fishes, and the Life History of the Eel (East of staircase).

The North Hall, containing the collection of Domesticated Animals.

The Bird Gallery, containing groups of British Birds and Nests; and in the Pavilion, at the West end, an exhibition of the Land and Fresh-water Vertebrate Animals of the British Isles.

The Fish Gallery, containing the Great Basking Shark, the grotesque Deep-sea Fishes (case 44), the Tunny (case 38), the Tarpon and Angler-fish (case 27), and the Lemon-Sole (case 30), etc.

The Shell Gallery, including a life-size model of a Giant Squid (Newfoundland), and of a Giant Octopus (California).

The East and West Corridors on the First Floor, containing the Okapi, African Antelopes, and Giraffes.

Light Refreshments will be supplied at Buffets in the North and South Corridors on the First Floor of the Museum, and at the end of the Bird Gallery.

Visitors travelling by the District Railway (or other underground railways in connection therewith) will be allowed free use of the company's subway, which leads from South Kensington Station direct into the grounds of the Museum.

Each member is entitled to a card for himself (which will not be transferable) and a card for a lady. (These cards have now been issued.) In addition to this, a limited number of Tickets will be sold to members of the Society, or to persons introduced by a member, at the price of 5*s.* each, if purchased before the day of the Conversazione. On that day the price will be raised to 7*s.* 6*d.*

Members can purchase these additional tickets by personal application, or by letter addressed to the Secretary at the Offices of the Society, John-street, Adelphi, W.C. In all cases of application by letter a remittance must be enclosed. Each ticket will admit one person, either lady or gentleman, and must be signed by the member applying for it.

Tickets will only be supplied to non-members of the Society on presentation of a letter of introduction from a member.

It will greatly facilitate the arrangements if members requiring additional tickets will apply for them at as early a date as convenient.

The Council reserve the right of stopping the sale of tickets or of raising the price, if it is found necessary, in order to restrict the number of visitors within reasonable limits.

Further particulars as to the musical and other arrangements will be given in the Programmes, which will be distributed on the evening.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A Meeting of the Colonial Section was held on Tuesday, May 9th, 1911, His Grace the DUKE OF ARGYLL, K.T., G.C.M.G., G.C.V.O., in the chair.

The CHAIRMAN, in introducing the reader of the paper, said the bank with which Mr. Williams Taylor was connected was as well known as any bank in the district of the London Adelphi. Mr. Williams Taylor himself had had a very varied experience in Canada, throughout which he had proved his metal. He was bred in the maritime province of New Brunswick, but gained his great experience as a banker in Ontario, especially in connection with the lumber trade. Then, for a considerable space of time, he lived in Chicago (and all who knew that city would know what that meant in the way of hard work), and he had also spent many years in Quebec and Montreal. During the past three years there had been such a rush to Canada that a new world had developed in the West, and it was greatly owing to the assistance which the Bank of Montreal had extended to settlers in the way of advancing them capital that that vast new prairie country had been developed. So great had been the emigration from this country to Canada that many landlords had started abusing Canada for depopulating their country districts. He pleaded entirely guilty to the charge; he had always told every sturdy man he had met in the British Isles that if he had a little capital and energy he would do much better by emigrating to Canada. After all, the rush to Canada could not go on for ever, and he did not think there would be the slightest fear but that this country would receive back a goodly number of its people in very much better health and fettle.

The paper read was—

CANADA AND CANADIAN BANKING.

By F. WILLIAMS TAYLOR.

I trust those who have honoured me by their presence to-day have not been lured within the precincts of this hall in the expectation of being edified by a learned discourse of a technical and theoretical nature. If so, they are doomed to disappointment; and I therefore preface what I am about to say with my apologies for permitting the Royal Society of Arts to have used a too imposing and perhaps misleading title for my modest effort. My only claim to a knowledge of the subject before us is that in my residence of forty years in Canada—my birthplace—I spent twenty-five thereof in the service of that great banking institution which I now have the honour and privilege of representing in London, whilst as an inspector of the institution in question I visited and revisited every city and town of importance, and was thus afforded unequalled opportunities of acquiring information of every practical description.

It is not my intention, nor my inclination, to deal with the subject of banking in Canada technically and theoretically, but rather to present to those who are not conversant with the facts, or who have not visited our Dominion, or studied its banking equipment and system, a brief survey of the country—the natural resources thereof, the industries which have

followed in sequence, and the practical side of banking as applied to the financing of such industries, and providing financial accommodation generally in a new country where conditions necessarily differ greatly from those prevailing in this old centre of civilisation—followed by some general comments on our banking system and its salient features.

Before proceeding further, I may perhaps be permitted to interpolate that we have fewer banking theorists in Canada than in most countries, and, curiously enough, we manage to get along quite well without them. As a rule, Canadian bankers are too fully occupied in the practice of their profession to indulge in theorising. I remember one of our most successful bankers once expressed to me his satisfaction that he had no official in the employ of his institution who indulged in essays on the theory and practice of banking. The remark was called forth by an historic adjudication that the head of a certain bank—now defunct—who had been in the practice of emitting serial discourses on banking management, had been sequestrated from his fellow-citizens for a term of years in the provincial penitentiary for malfeasance of office.

Thirty-four years ago Canada was constitutionally a vast disjointed territory stretching from the Atlantic to the Pacific, and from the international boundary line north, to a land of which it has been said "the mountains are nameless, and the rivers all run God knows where." Under the ever-memorable administration of Sir John Macdonald, the process of political integration known as Confederation was inaugurated in 1867, and presently the whole country became welded into the Dominion of Canada.

In addition to British Columbia, which comprises the spacious area between the Rockies and the Pacific Ocean, Canada has been divided by Nature into two countries, an East and a West, separated by Lake Superior and Georgian Bay, water areas bigger than Scotland, and by a stretch of wild rough country north thereof some six hundred miles in width, largely uncultivable and therefore ill-adapted for settlement. It is true that north of the Height of Land—say, roughly, one hundred miles north of the great bodies of water referred to, and south of James' or Hudson's Bay—there is well-timbered territory and land more or less suitable for agricultural purposes, but it is highly improbable that this district can or will support more than an exceedingly sparse population for many years to come. The far-seeing fathers of Confederation recognised the potential wealth of our Western prairie country, and the vital necessity of linking it to British Columbia on the Pacific Coast, and to the eastern provinces—hence the Government support accorded the construction of the Canadian Pacific Railway, the creation of which railway was one of the conditions upon which British Columbia entered Confederation.

I may interject that for the reasons given the natural channel of trade between the western portion of Canada and the United States of America is north and south, but our good cousins to the south of the forty-ninth degree of latitude shook off their allegiance to Great Britain in 1776, and there has since come into being north of that latitude a nation which, in order to preserve its political entity, develop its resources, and keep flying Britain's Imperial flag, has been compelled at vast expense to create highways in defiance of Nature, and thereby to divert the flow of trade eastward and westward. That Canada has been successful in carrying out what thirty-four years ago was by many considered a mad policy, is a matter of history. We can all recall the time when the Canadian Pacific Railway was the subject of heated discussion in and out of the Dominion Parliament, some doubting if it ever would be completed, or even kept open if it were, whereas to-day its securities vie in popularity with the best in this or any land, and it is admittedly one of the greatest creations of modern days, with ramifications undreamed of at its inception, and with a future which the least sanguine would hesitate to limit. Nor is this all, for presently the Grand Trunk Pacific and Canadian Northern Railways will become trans-continental lines.

Now it will be obvious even to those who have not visited Canada, that a country some 3,500 miles in width, and extending from the international boundary line to the North Pole, must have a variety of climates, of physical features, and of natural resources; and in order that I may make clear to the uninitiated the nature and scope of a banking system which provides for the financial requirements of such a great territory, I purpose, with your permission, approaching my subject province by province.

The Provinces.

We speak in Canada of the Maritime Provinces, consisting of Nova Scotia, New Brunswick and Prince Edward Island; of Quebec; of Ontario; of the North-West, comprising the

Provinces of Manitoba, Alberta and Saskatchewan; and of British Columbia and the Yukon.

PRINCE EDWARD ISLAND.

Prince Edward Island, the smallest of the maritime group, our baby province, was originally discovered by one of the Cabots in 1497 or 1498. Jacques Cartier, who followed in 1534, is said to have described it as "low-lying, without harbours, the most beautiful land it is possible to see," and indeed it is a peaceful, beautiful spot, where poverty is unknown and all are "content with their lot, contented and happy with what they have got." It changed hands continually in its early history, until finally ceded to Great Britain by the French in 1763. It has an area of about 2,200 square miles, or, say, 1,400,000 acres, of which over nine-tenths are cultivated; hence the designation sometimes given to it of the "million-acre farm." The surface of the island is gently undulating, and eminently pastoral and agricultural. At one time it was densely covered with beech, fir and other trees, but though still well wooded, the forests have, from a commercial point of view, disappeared. There are no minerals of importance, and the principal industries are agriculture and fishing, with a limited amount of manufacturing, as compared with other parts of Canada. The island is well populated for its size, the inhabitants numbering 103,000, mainly of English, Scotch, and Irish extraction, with about 14,000 French-Canadians. Those who have not eaten Prince Edward Island oysters have something to live for! The banking requirements are not extensive, being mainly to traders, wholesale and retail houses, and in connection with the fisheries. There have been several local banks in the history of the province, but all have been absorbed or otherwise ceased to exist, branch banks having taken their place.

NOVA SCOTIA.

The Nova Scotia peninsula was the most important portion of the old French province of Acadia. Its authentic history dates from 1604, when the fortified town of Port Royal—the oldest in North America next to St. Augustine in Florida—was established by the French. Within the next one hundred and six years Port Royal was successively captured by the English, restored to France, surrendered to the English, ceded to France, and finally captured by the English in 1710. In 1749 Halifax was founded, and a civil government established there to replace the military government of Port Royal. In 1755, owing to the persistent refusal on the part of the Acadians to take the oath of allegiance to England, they were removed. Hence Longfellow's highly inaccurate but charming "Evangeline." Visitors will have no difficulty in finding her home—"the little village of Grand Pré," where "still stands the forest primeval, the murmuring pines and the hemlocks." Between 1776 and 1783 over thirty thousand loyalists poured into the province from the rebellious States to the south, and about the same time there was a large Scottish immigration. The present population of the province is about 475,000, and is almost entirely of Anglo-Saxon descent, with perhaps 10 per cent. of French-Canadians. Halifax, the principal city, has a population of 55,000. Its harbour, which never freezes over, is one of the best, not only on the North-American coast, but in the world.

In size Nova Scotia is, roughly, 350 miles by 100 miles at its greatest length and breadth. Cape Breton, separated from the mainland by the Gut of Canso, has an extreme length and breadth of 100 miles by 85 miles. The total area of both is about 21,000 square miles. It was in Cape Breton that the famous fortification Louisburg was erected by the French Government early in the eighteenth century, at a cost of some £3,000,000, and captured by the English in 1758.

The topographical feature of Nova Scotia is an undulating surface, with beautiful fertile valleys lying between low mountain ranges seven hundred to a thousand feet in height, while the country resembles closely in general appearance the north of England and Scotland; hence its name. Few northern countries contain greater inherent wealth and variety of natural resources. The most important of these is agriculture, with dairying, fruit-growing, mining, fishing and lumbering. The coal-mines, situated on the seaboard, are practically inexhaustible, as are the fisheries, which—like those of Newfoundland—have been operated for several centuries. At one time Nova Scotia had immense quantities of standing timber, and the province was famous for its wooden ships. Much of the timber has disappeared, although there are still large and valuable areas of small spruce. One of the most important industries of the province is the manufacture of iron and steel, the plant of the Dominion Steel Company at Sydney being one of the largest in Canada. Otherwise, manufacturing

is on a very moderate scale as compared with the provinces of Quebec and Ontario. The Annapolis Valley is famous for its fruit—indeed, its apples cannot be surpassed, and the industry is of great importance.

A feature of Nova Scotia and New Brunswick is that both are most thickly settled along the coasts, owing to the fact that the early settlers hesitated to venture into the interior, partially through fear of Indians, and partially because the coast waters and inlets teemed with fish, giving a ready supply of food, in addition to providing a natural means of communication in days when roads were non-existent. It followed in consequence that the inhabitants took to fishing and lumbering—both offering a quick return for their labours—to the neglect of agriculture, and even to-day nothing like full advantage is being taken of the agricultural possibilities of Nova Scotia. This applies still more to New Brunswick, a large portion of the interior of which province is dense forest, visited mainly by lumbermen and fishermen, and hunters in pursuit of the famous moose.

New Brunswick.

New Brunswick is 230 miles by 190 miles in extent at its greatest length and breadth, with an area of 28,000 square miles. It was originally a part of Acadia, then of Nova Scotia till 1784. Apart from the earliest settlers—the French, whose descendants now number some 85,000—the population of about 250,000 is of pure British stock, many—as in Nova Scotia and Ontario—the descendants of those loyalists who left comfort and prosperity behind them in the United States, and came north in 1776 to what was then considered the end of the world, simply and solely out of loyalty to the British flag. Topographically, New Brunswick is much more broken, with many more mountain ranges, than Nova Scotia. The chief industries are lumbering and fishing. There are cotton, fish-canning and other factories, but otherwise manufacturing is on a smaller scale even than in Nova Scotia. In the valley of the St. John River, and elsewhere, there are agricultural areas with land of the finest quality. The principal city, St. John, founded by loyalists, with a population of 57,000, has an excellent harbour on the Bay of Fundy.

From lack of local opportunity many of the young men of the Maritime Provinces have sought their fortunes in other parts of the Dominion or abroad, and full credence is given to the statement that the Lower or Maritime Provinces have turned out more men of note in proportion to their population than any other part of the Dominion. This is not due to a fish diet, but to the excellent quality of the original stock, coupled with an educational system which has been good for many years. Until the last five years there has been little immigration for a century into the Maritime Provinces, the tide running more strongly towards the west, but a fair proportion of immigrants are now going in, and the number should and will increase.

Two of our most successful banks are of Maritime Province inception — namely, the Royal Bank of Canada (formerly the Merchants' Bank of Halifax) and the Bank of Nova Scotia. Nor must the Bank of New Brunswick be overlooked, an institution which came into being in 1830, and although of modest size, with few branches, has a record of which it may well be proud. Several Maritime Province banks have come and gone.

In the cities of Halifax and St. John the banking accommodation is somewhat similar in character to that required, say, in places of similar size in this country, but in the small towns—most of which are along the coast—banks are called upon to finance small traders who often combine shopkeeping with fishing and lumbering operations. Advances are made that fluctuate in amount throughout the year, but seldom run off, as the loans for different purposes overlap each other. This is not an attractive form of loan business, as the banker's capital is thereby tied up, making him somewhat of a permanent silent partner, but it is a class of accommodation that has always been demanded by the requirements of the community, was encouraged in the past by local banks, and which it is now difficult to avoid. There is little poverty in the Maritime Provinces, nor is there great accumulated wealth. No figures are published showing the proportion of bank deposits in the separate provinces of Canada, but *per capita* they are certainly less in the provinces in question than in Quebec and Ontario.

These provinces are traversed by the Intercolonial and Prince Edward Island Railways, both Federal Government roads, the former with termini in Halifax and Montreal. In road-bed and equipment, the Intercolonial will compare favourably with railways in England. With the aid of an American charter, the Canadian Pacific Railway cuts across the State of Maine from Quebec to St. John—its Atlantic

winter port for freight—and it has also running rights over the Intercolonial to Halifax. The former Company has recently acquired the Dominion Atlantic Railway, running from the Bay of Fundy, through the Annapolis Valley to Halifax. There are other railways, which time will not permit me even to mention.

Quebec.

Quebec, the next province in geographical sequence, has an area of about 350,000 square miles. Roughly, the province is about 1,000 miles east and west by 300 north and south—or, say, about three and a half times as large as England and Wales. The population is about 2,000,000, of which some 1,300,000 are French-Canadians. I should like to say regarding the latter that the process of transforming Frenchmen into Anglo-Saxons is a slow one—it took a good many hundreds of years to accomplish this end in England—but there is no room for doubt, not only about the devotion of the French in Canada to their country, but that they have a keen appreciation of the advantages of British rule, which has left them in full enjoyment of their civil and religious liberties. On the other hand, all broad-minded British-Canadians look upon their French fellow-countrymen as one of the country's valuable assets. Few countries, if any, have had such a respectable class of immigrants as the French who came to Canada in the eighteenth century. It is true that they are, with rare exceptions, seldom conspicuous in great commercial and financial undertakings, and as farmers are unprogressive; but in striking contrast they have given us many of our most brilliant statesmen and politicians, including Sir Wilfrid Laurier himself, of whom Canadians of every political and religious creed are proud, while in the legal profession they are prominent, and in the labour market invaluable.

In the country districts the "habitants" retain all the charm of their Normandy and Brittany ancestors — a simple, hard-working, healthy, thrifty people. "On the long winter evenings the men still sit before the blazing maple-log greasing their 'bottes sauvages,' while the wooden 'sabots' of the women click gaily on the snow-white pine floor, or their felt slippers thud gently to the hum of the spinning-wheel." Truly we English-Canadians have been singularly indifferent to the picturesque side of our fellow-countrymen.

The surface of this province is varied with innumerable rivers, lakes, streams, forests, lofty hills and mountain ranges. Jacques Cartier discovered the St. Lawrence in 1535, and in 1608 Champlain founded the City of Quebec, "that stronghold of New France, now the antiquarian gem of Canada, where first fluttered from the stately glacis the lilies of France on their azure field, where the best blood of France held sway in citadel, chateau and seigneury." What a roll-call of illustrious dead must haunt that grand rock high above the mighty river. Surely there is nothing in North America to equal it in historical and picturesque interest.

The capture of Quebec by Wolfe in 1759 was an event in English history, the importance of which time accentuates.

It is estimated that some 116,000 square miles of the province are covered with merchantable timber; the main portion of the remaining lands is well adapted for agriculture, the soil being rich and loamy. The natural resources include timber, minerals, fisheries, etc., while its unsurpassed water-powers are of the utmost value for manufacturing and lighting purposes.

At various periods in the history of Quebec we have had French-Canadian banks of some importance, but these have not been so successful as their Anglo-Canadian competitors, and only three now remain, namely, La Banque d'Hochelaga, La Banque Provinciale du Canada, and La Banque Nationale—all of good standing. In the matter of manufacturing, the province of Quebec comes second to Ontario. Montreal, with a population of 500,000, is the commercial, financial, railway and manufacturing centre of the Dominion, and is situated at the head of sea navigation.

The Bank of Montreal was organised in 1817, the Quebec Bank in 1818, and the other existing banks which originated in the Province of Quebec are the Merchants' Bank of Canada, Molsons' Bank, the Union Bank of Canada, and the Eastern Townships Bank.

Ontario.

Ontario—formerly called Upper Canada—was partially explored by Champlain in 1615, but French settlements did not follow as in Quebec, the warlike Iroquois Indians holding sway over the province for many years; therefore, the founders of the province may be said to have been the loyalists who emigrated from the United States after the American War of Independence. The province of Ontario has been called the "backbone of Canada," and the expression is not inapt, situated as it is midway

between the east and the west, and occupied by a prosperous community, with an unadulterated population of between two and three millions of people overwhelmingly of British extraction, devoted adherents of Anglo-Saxon laws, religion and traditions. The area is 260,862 miles, of which 40,354 miles are water, and approximately one-half the whole province is still covered with timber. The surface generally is an undulating plateau, without great elevations. The province is rich in minerals, timber and agricultural lands, and the lake fisheries are of great value. The timber resources of Ontario consist principally of pine and spruce of unexcelled quality, of which the annual cut is about 600,000,000 feet, valued approximately at 9,000,000 dollars.

Its mineral resources include the famous cobalt mines, the output for the province being valued in 1909 at 32,700,000 dollars.

Fruit is produced in great quantities—the Niagara Peninsula in particular being famous for its apples, pears, peaches, grapes, etc., which grow to perfection. The province is the greatest manufacturing district in Canada, with industries of every description and almost limitless water-power, so that it is, in fact, a self-supporting community. The province has a network of railways, the total mileage aggregating 8,400; also great waterways, extensive canals, and splendid inland shipping facilities.

Toronto, the capital of the province, has a population of over 300,000—about the size of Dublin—and is admirably situated for lake navigation. It is the next most important manufacturing centre to Montreal, and is a well-kept, well-governed city, with as imposing buildings and as fine parks as any city of its size in the Empire.

Ottawa, the capital of the Dominion, next in size, with a population of 90,000, is beautifully situated on the Rivers Ottawa and Rideau, and forms with its Parliament buildings a picture which we Canadians regard with what we hope is pardonable pride. With boundless water-power at its door, it too has become an important manufacturing centre, particularly in those industries allied to the lumber trade. The splendid rivers referred to extend far into the north, into valleys famous for their white pine, which is thereby all made tributary by Nature to the city.

Hamilton, with a population of 75,000, is also a busy and growing hive of industry. Other important manufacturing points are Brantford and Peterborough, while London, with a population of 50,000, is an important distributing centre of the Niagara Peninsula. There are innumerable other towns of varying importance, each with industries in very many cases operated by water-power, all—with rare exceptions—active and progressive, not overlooking Fort William and Port Arthur, strategically situated at the head of inland navigation. The climate is very similar to that of the Eastern Provinces, but with a more open winter along the St. Lawrence, the Great Lakes, and the Niagara Peninsula.

Fur-bearing animals and game abound in the northern portions of the Province.

The banking requirements of a territory with such varied resources and industries are naturally unlimited, and the best evidence thereof is that no less than twelve of our existing twenty-nine banks originated in and have their head-quarters in Ontario, among them the Canadian Bank of Commerce, the second in size and importance of all our banks.

NORTH-WEST PROVINCES.

The North-West Provinces, comprising Manitoba, Alberta, and Saskatchewan, formerly called "Rupert's Land," extend from a short distance west of the head of Lake Superior into the Rocky Mountains, say about a thousand miles in width and extending from the American frontier into the frozen north. They have a combined area of about 2,500,000 square miles. The geological formation of the north-west differs from that of any other part of the Dominion, the whole territory having at one time been a great inland sea, which accounts for the richness of the soil, probably the most fertile in North America. Prior to 1811 the territory had no written history beyond the brief records of the Hudson's Bay Company. In 1670 a monopolistic charter was granted by Charles the Second to "the Governor and Company of Merchant Adventurers trading into Hudson's Bay"—by usage abbreviated to the "Hudson's Bay Company"—to so vast and unknown a territory that it could not be specifically defined, but as the actual wording was "the bays, rivers, lakes within the entrance to Hudson 'Streights,' together with all the lands, countries and territories upon the coasts and confines thereof," the Company legitimately exercised administration over the whole territory from Lake Superior to the Rockies and north to the Polar regions. Not only so, but their tenacious hold enabled them subsequently to secure grants westward to the Pacific coast, including what is now British Columbia. At

that time the only inhabitants were Indians and Hudson's Bay Company traders. In 1811 Lord Selkirk obtained from the Hudson's Bay Company a grant of 116,000 square miles, conditional upon the establishment by him of a colony and upon supplying the Company with men. The headquarters of his settlement were near the present site of Winnipeg, and, by the way, I have been told that wheat has been grown continuously, without fertilisation, on land in the Selkirk—or Red River—Valley ever since. In 1836 the Hudson's Bay Company repurchased for £84,000 the 116,000 miles previously granted to Lord Selkirk. In 1867 the Canadian Government claimed the whole Hudson's Bay Company's territory by right, but by agreement gave the Company £300,000 in cash, with a right to one-twentieth of all lands surveyed for settlement within fifty years, accompanied by certain guarantees against undue taxation. The main portion of the whole region in question is rolling prairie country, admirably adapted for agricultural purposes, and particularly for wheat; in fact, it has become the most famous wheat area in the world, as regards both quality and extent. Obviously, therefore, agriculture is the all-important industry; though there are great areas of coal of fair quality, and a small amount of standing spruce, cedar and tamarack in the most eastern and northern districts. The North-West Provinces have 7,600 miles of railway.

Winnipeg is the great distributing centre of the West, and its growth is one of the wonders of the day. In 1870 the population was 215; in 1901, 42,000; while to-day it is estimated at 152,000. The population of the whole north-west has likewise increased by leaps and bounds, namely, from 43,000 in 1871 to (estimated) 1,100,000 in 1911. An idea of the development of the north-west may be gathered from the fact that in 1870 there was not a chartered bank in the whole district. To-day there are 592 branches of various banks. The population is somewhat mixed, as a result of immigration from the whole world, but the great majority are of Anglo-Saxon origin, and the sentiment—thank Providence and good government—is British to the core, and we believe will always so remain.

The banking accommodation required is almost entirely to the grain trade, to wholesale and retail traders and to farmers and cattle breeders. There is one local bank, formed in 1905, the Northern Crown, with its head office in Winnipeg.

British Columbia.

British Columbia, the Maritime Province of the Pacific, extends from the summit of the Rockies to the Pacific Ocean, and is, roughly, 700 miles by 400 miles in size. Its southern boundary is the United States of America, running north to the sixtieth parallel of latitude. Its area is about 385,000 square miles, of which less than 100,000 miles is said to be cultivated or capable of cultivation. In addition to the Rockies there are three other mountain ranges, with valleys between, more or less suitable for agriculture, the Okanagan Valley notably so.

Sir Francis Drake is supposed to have sighted Vancouver Island in 1578; in 1592 the Spanish explorer Juan de Fuca gave his name to the Straits, and explored the waters between Vancouver Island and the mainland. In 1778 Captain Cook, under instructions of the British Government, explored the coast. In 1792 he was followed by Captain Vancouver. It is a fair statement of fact that the credit belongs to the Hudson's Bay Company of keeping the British flag flying in the early days of this territory, for the Government of the day took no interest in the matter. In 1867 British Columbia entered Confederation, the primary stipulation being that it was to be connected by rail with the Eastern Provinces; hence, as previously stated, the Canadian Pacific Railway. The climate is salubrious on the coast, corresponding closely with that of the south-west of England, and has proved attractive to all, but particularly to English people. The population, estimated at 200,000, is essentially Anglo-Saxon, and British in sentiment. The most important natural resources are minerals, lumber, and fisheries, all of immense value. There are also rich agricultural and fruit areas, the latter unsurpassed—in fact Nature has been prodigal, as British Columbia contains the greatest areas of merchantable timber in North America, coal which seems in inexhaustible quantities, unsurpassed fisheries, a wonderful climate, free from extremes of heat and cold, a commanding seaboard position, and some of the grandest scenery in the world. A large proportion of the province is a sea of mountains, many parts thereof rich in minerals, most of it unfit for cultivation, but all picturesque to a high degree. The cultivable areas are extremely fertile, and admirably adapted to fruit growing and mixed farming. There is only a limited amount of manufacturing, apart from lumber. Salmon-canning is an important industry. In natural resources there is a great similarity between British Columbia

and the Maritime Provinces. The growth of Vancouver, the principal city, has been extraordinary; less than forty years ago it was an unbroken forest; in 1901 it had a population of 27,000; to-day it has 100,000 at least. The banking requirements are mainly in connection with the financing of the products of the forest, the field, the mines and the fisheries, and the wholesale houses and retail dealers. The Bank of British Columbia, incorporated in 1862, an institution of importance and of excellent standing, was absorbed in 1900 by the Canadian Bank of Commerce. Its shares were largely held in this country. A small local bank called the Bank of Vancouver has recently been established.

Résumé.

Now those who have had the patience to follow me so far will be better able to form an idea of the nature of the banking facilities required by a country so vast that it is equal to an aggregation of countries. There are different climates, different resources, and some mixture of nationalities, and various provincial governments, but only one flag, and the entire country is united in its respect for Anglo-Saxon laws and institutions, and in devotion to this Mother Country. The whole territory is served, and admirably served, by twenty-nine banks with about two thousand five hundred branches, the combined paid-up capital and reserve being about £38,000,000.

Early Banking.

But I must retrace my steps, and first touch lightly upon the early history of banking in the Dominion.

Prior to the capture of Quebec by Wolfe in 1759 there is no record of any form of banking, and there was probably little need for banking institutions, though the Intendant Bigot indulged in forms of high finance coupled with unadulterated corruption which have not been equalled in modern days—not in Canada, at any rate—and which resulted in 1763 in a sentence which offers certain points which I confess I do not regard with disfavour. As Dr. Doughty, the historian, relates, the finding of the courts against this eighteenth-century financier was as follows:—"In reparation, the said Francis Bigot is condemned to make the *amende honorable* before the principal gate of the Tuileries, whither he shall be escorted by the public executioner in a tumbril, having a rope about his neck, and bearing in his hand a lighted torch of yellow wax two pounds in weight. On his chest and on his back shall be placed a placard with the inscription—'The Public Administrator, Perfidious Thief,' and then kneeling bare-headed and with bare feet, clad only in his shirt, he shall declare in a loud and intelligible voice that during his administration of New France, in peace and in war, he has been guilty of the frauds, extortions and thefts set forth in the indictment." Incidentally, he was condemned to execution, which was, however, commuted to confiscation of his ill-gotten wealth and banishment from the realm. Who shall say after this that Louis Quinze had not a sense of justice?

In 1792 the Canadian Banking Company was organised by certain English merchants, but its existence was brief, and beyond the fact that it exercised the function of note issue it left about as little record behind as "the canoe which crossed the bosom of some lonely lake a thousand years ago."

The retirement by the British Government of their Army bills issued to meet the expenses of the war of 1812 with the United States, marked another stage in the course of events, and led to the establishment in 1817 of the Bank of Montreal. From lack of formal legislative authority this bank started business under articles of association, though the charter was not granted by the Quebec Legislature until 1821, nor the Royal assent secured until 1822. The Quebec Bank came into being in 1818, the Bank of New Brunswick in 1820, the Bank of Nova Scotia in 1832, others following in due course. Further charters were granted about the same time, but the institutions securing them have come and gone. Those, however, just mentioned, remain and have prospered, and it may be said that the records of the Bank of Montreal in particular embrace the financial history of Canada. In the period between 1829 and 1866 Breckenridge tells us that not a single chartered bank went down in failure. Since that date a good many have appeared and disappeared, but the same remark is, of course, applicable to England and to other countries. The first general Bank Act was passed in 1871, four years after Confederation, unifying the rights and privileges of each as their pre-existing charters expired later on. Under this Act the various charters were extended to 1881. Since then charters have been regranted decennially, and revision also takes place every ten years.

You will doubtless all agree that it will serve no useful purpose on an occasion such as the present to recite further in detail the numerous

alterations, additions, restrictions, failures and successes which go to make up our banking history. To the student and banker the subject contains much of interest and a good deal that is edifying, and to such I would recommend Breckenridge's "History of Banking in Canada"—a carefully-prepared work containing an accurate recital of the facts. A more recent outside but friendly criticism—also American—of our system, by Mr. Joseph French Johnson, Dean of the New York University School of Commerce, will also be found interesting and instructive, particularly as it comes from a citizen of that great and wonderful nation occupying the other half of the North-American Continent, the banking system of which differs so essentially from our own. I shall therefore proceed to deal with our system as at this date, referring briefly to some of its distinctive features, and the application of the whole to the financial affairs of the Dominion.

Canadian Banking System.

In Canada, as in all countries, the banking system is the result of a slow process of evolution, but I think I may be permitted to state that we started right—thanks to those hard-headed Scots, who were not only conspicuous in the promotion of our earliest banking institutions, but in commerce and in the administration of the affairs of the country. Naturally they and their English and Irish cousins embodied in their articles of association, and in their rules, regulations, and general practice, the fundamental principles of the institutions of the Mother Country, gradually deleting features inapplicable, and modifying and creating, in accordance with the different financial and trade conditions, the greater area of operations, and the needs of the community, until a point has been attained where we can—without egotism—say that we have a system, not perfect, it is true, but admirably adapted to the requirements of the Dominion, probably as much so as the banking system of any other country.

Now, it is the case that the aim on the part of the bankers of Canada thus to adapt themselves to the requirements of the people—with the wise co-operation of the Government, between whom there has continuously been the closest sympathy—has not only accrued to the advantage of the banks, but has been a factor in the development of the country, its trade, its commerce, its transportation facilities, its resources, its financial stability, and in natural sequence in our national credit, particularly in London, the importance of which is beyond computation. Johnson says Canada's system "was not created by lawyers or statesmen to meet the fiscal needs of the Government, but has grown up gradually under the fostering care of experienced bankers, no changes having been made until experience proved them necessary or advisable," and I agree, but may truly add that the system would never have been brought up to its present pitch of excellence had not our Premiers and our Ministers of Finance had entire confidence in those bankers.

Not in any spirit of unfriendliness I venture to assert, regarding the United States of America, that if they had had a banking system and enjoyed currency laws corresponding with Canada's, it would have made an infinite difference, and the world would not stand bewildered and amazed at the financial crises which periodically convulse that great and rich country—and, *per contra*, nothing more clearly illustrates the richness of the United States and the virility of its people than that, in spite of defective banking and currency laws, the country has made and is making so marvellous a progress that it fills the universe with profound awe.

Our Canadian system is in effect a unifying and co-operative one. The bank, acting as a medium, receives deposits from the prosperous farmers in agricultural districts, where there is little demand for borrowed capital, lending it throughout the length and breadth of the land, where it is required by the business requirements of merchants, manufacturers, miners, millers, and financial houses. The branch banking system which affords us this facility, enables us to pay depositors a rate of interest with which not only are they well satisfied, but which enables the banks to advance to the said merchants, manufacturers, etc., at a more uniform and moderate rate than would otherwise be the case. The rate of interest on what we call savings accounts is 3 per cent. throughout the whole Dominion, and the rate of interest charged on loans varies little—the difference being not more than, say, 2 per cent. between the rate paid by the trader in some remote Atlantic fishing village, the rich merchant or manufacturer in the commercial centres, the lumberman, the miner, even the farmer in the north-west, or the tradesman in British Columbia. Banks may stipulate for, take, reserve or exact any rate of interest or discount not exceeding 7 per cent. per annum.

Again, without any intention of making invidious comparison with rates in the United

States, I may say that entirely opposite conditions exist across the line. In some of the western states, for instance, 9, 10 and 12 per cent. is paid by borrowers who would not be called upon to pay for similar accommodation more than, say, 6 per cent. in Canada. It is true the banks in such districts pay a much higher rate of interest on deposits than with us, but the margin between the loan and deposit rates is greater in that portion of the United States, and the heavy charge for loans is a serious disadvantage to the community.

Formation of a Bank.

The Bank Act of Canada aims at protecting the public against the creation of weak or improperly-managed banking institutions, and with this object in view in the first place prohibits the use of the name "Bank" except under Government charter. In the formation of a bank the procedure is then as follows:—Respectable men of substance who are required to become important shareholders must agree to act as provisional directors, and are obliged to secure from the Parliamentary Committee on Banking and Finance a favourable report upon their project. The Committee proceeds to satisfy itself that the enterprise is *bonâ fide* not only in its inception but in its aims. Should the full capital—which cannot be less than 500,000 dollars — be subscribed, and 250,000 dollars thereof paid up within one year, a meeting of shareholders may be called and the permanent directors elected, the latter applying in due course to the Treasury Board for permission to issue notes and commence business, the authority being granted only if the requirements of the law have been fully satisfied.

Currency.

In the early days of Canada the Hudson's Bay Company emitted to an extent, and from a date unrecorded, a form of paper money, but until the middle of the eighteenth century it is doubtless the case that the principal money of the country consisted of beaver, moose and other skins, and probably brandy, developing gradually into "card money," issued without restraint in the closing decades of New France, followed by British Army bills, and finally by the banknote system of to-day.

The present currency system of Canada is essentially elastic, automatically expanding and contracting according to the demands of trade and variations of the seasons. All banks may issue notes of the denominations of five dollars or multiples thereof, to the extent of their paid-up capital, free of tax or specific security, such notes being a prior lien against the assets of a bank, and also against a liability on the part of the shareholders up to twice the amount of the subscribed capital. In addition, note-holders are further protected by what is called the Circulation Redemption Fund — under which each bank is compelled by law to deposit with the Government 5 per cent. of its average circulation, this fund constituting a common insurance. There have unfortunately been failures of several of the smaller banks since this provision became law in 1890, but not once has the fund been resorted to. The result is absolute confidence in bank-notes as a medium of exchange. Along with silver and copper coins, they constitute almost the sole circulating medium; in fact, there are parts of Canada where a gold piece is looked upon with a certain amount of curiosity, almost amounting to suspicion. No one thinks of carrying gold for pocket-money. The Dominion Government issue notes in denominations of one, two and four dollars, and of fifty dollars and upwards. In 1908 there was outstanding 68,000,000 dollars thereof, of which the main portion was in denominations of 500 dollars upwards, which are entirely held by the banks in their reserves. Dominion Government notes are secured by not less than 15 per cent. of those outstanding in gold; notes in excess of 30,000,000 dollars must by law be secured by an equal amount of gold.

Banks may issue notes in excess of their capital during the usual season for moving the crops, viz., from October 1st to January 31st following, to an extent not exceeding 15 per cent. of their combined unimpaired paid-up capital and reserve. On such excess, interest at the rate of 5 per cent. per annum must be paid to the Government.

Call Loans and Reserves.

Some of the leading Canadian banks loan largely on call and to the Stock Exchange in London and in New York at the rates of interest of course prevailing in those markets, which rates are usually naturally much lower than for call money or for commercial business in Canada. In actual practice such Canadian banks earn little more, and may in fact earn less, as a rule, on such loans than they pay on deposits in Canada for the main portion thereof, which seems like bad banking, but the object is obvious, namely, to keep their reserves employed even at a small rate of interest, rather than have the whole amount lying idle in their vaults in the shape of bullion.

As a safeguard against financial exigencies, the policy of the Bank of Montreal for many years has been not to lend on call in Canada, but in London and New York, where money can be taken off the market without disturbance for its own requirements, or for the strengthening of the Canadian position, should necessity arise. This policy, though disadvantageous in the matter of interest, is sound not only as applied to the institution itself, but to Canada as a whole—in fact, a sheet-anchor of recognised importance.

Dividends.

From the bankers' point of view, the margin in the rate of interest paid on deposit and received on loans in Canada is satisfactory as compared with this country, and you might therefore wonder why bank dividends in Canada are not as high as in England and Scotland. The explanation is that in Canada banks have far less free money—that is, deposits not bearing interest—than in Great Britain, and the second reason lies in the fact that in Canada, as in all new countries, banks suffer more numerous losses than in an old civilised centre such as this, where the permanence of business establishments makes for more stable conditions.

Warehouse Receipts.

One of the conspicuous features and wisest provisions of the Canadian Bank Act, and one which has enabled banks to an incalculable extent to assist in the development of the trade of the country, is that relating to warehouse receipts. In a new country such as Canada capital is scarce, but opportunity, energy and ability plentiful. Now for a bank to advance the money at its disposal on the security of the personal qualities mentioned would be obviously unsound banking, but under the terms of Sections 84-90, inclusive, of the Bank Act, a bank may lend not only to individuals on the security of goods, wares or merchandise against hypothecation of warehouse receipts and bills of lading, representing such goods in the custody of a third person, but they may advance in this manner to the actual possessor of the goods on his own receipt, such receipts vesting prior inalienable rights in the bank from the date of the acquisition thereof; in other words, the banker acquires a direct unregistered lien upon the securities represented by the receipts as against all other creditors. The beneficial result of this law is that a bank with confidence in the probity, ability and energy of a customer, readily advances with reasonable margin to an extent which would never be entertained otherwise, and a borrower is thereby enabled to carry on a business largely in excess of that which would be possible under other circumstances, at the same enjoying all the advantages of having his goods in his own possession instead of in the custody of a warehouseman. Johnson states that this form of security makes our banks silent partners in our wholesale and manufacturing businesses, and I suppose this is one way of looking at it, with this all-important qualification, that the bank of course embarks its money against a maximum profit represented by interest of only, say, 5 or 6 per cent. per annum.

It may interest you to have illustrated the method by which the banker advances to, say, a lumber firm, under the Act relating to warehouse receipts. Let us take the case of a firm of lumbermen with a capital of, say, £200,000 invested in saw-mills costing £40,000, and timber limits £120,000, the balance being represented by book accounts, bills receivable, and manufactured lumber. As the winter approaches the firm applies to their banker for a loan of, say, £60,000 for forest operations, to be availed of over a period of about five months. Concurrent with each advance the banker takes from the firm a formal undertaking to furnish security on the logs and lumber to be created. First the lumberman buys and sends into the forest-shanties supplies for the lumbermen or shantymen, and for the horses; also plant, including bob-sleighs, saws, axes, chains, ropes, etc., required in the operations. In Eastern Canada this would be attended to in November. The shantymen arrive in due course, and proceed to build their shanties, made of logs. By this time the snow is on the ground, which suits their purpose, and they proceed to fell the trees, which are cut into lengths, skidded, i.e., piled in heaps, to be removed by teamsters on bob-sleighs along snow roads sprinkled with water, which, freezing hard, gives them solidity, to the nearest ice-covered river or lake. This process continues during the whole winter, until perhaps towards the end of March, the firm receiving further advances from time to time from the banker. Then with the thawing of the ice this stage of the operations ceases; some of the men are paid off, while the remainder drive the logs down the rivers—one hundred or two hundred miles, as the case may be—to where the mills are situated. There the logs arrive probably in June, when the "undertaking" referred to is supplemented by a security receipt, as it is

called, similar in character to a warehouse receipt. The process of converting the logs into lumber starts forthwith, and usually continues during the whole summer months. Towards the end of the summer the green lumber is ready for the market, and in due course is converted into cash or bills, and the banker repaid; but only by gradual process, as almost invariably one season's operations overlap another, viz., the banker is called upon for fresh advances before the previous ones are liquidated.

Another illustration would be the financing of the great cereal crop of the West. The grain dealer borrows from the bank on his personal receipt to pay the farmer; presently, when the grain is moved east, the railway bill of lading takes the place of the receipt. The bill of lading is later exchanged for an elevator receipt, which in due course is exchanged for ocean bill of lading, which accompanies the draft drawn on the firms abroad to whom the grain is sold, and from the proceeds of which draft the banker is reimbursed.

I have only given you two illustrations out of many, from shipbuilding to egg-packing. A very large part of the commercial banking business of Canada is carried on on such lines, but its scope cannot be better described than by reciting Clause 3, Section 88 of the Bank Act:—

"The bank may lend money to any person engaged in business as a wholesale manufacturer of any goods, wares and merchandise, upon the security of the goods, wares and merchandise manufactured by him, or procured for such manufacture."

It is probably as sound commercial banking business as can be found in most countries. There are occasions when the most gilt-edged securities cannot be realised readily, whereas the necessities of life can be marketed under any conditions. The banker must be careful, intelligent, and not too trusting. It is difficult for him, often impossible, to know—even by observation—whether the goods he has been advancing against actually exist to the extent hypothecated, and a borrower who sets out to defraud his banker can usually do so; that is the weak point. Should the borrower come to grief, the bank can, after a formal demand for payment, step in and take possession of the goods, realising them to the extent necessary to recoup itself. There is no registration of warehouse receipts, and a warehouse receipt cannot be taken to secure a pre-existing debt.

Bank Inspection.

Our system of bank inspection corresponds in general principles with that prevailing in this country, and is highly satisfactory if the duty be efficiently performed. The inspector or inspectors with their assistants visit each branch, unannounced, at least once a year, taking possession, for the time being, of the cash, securities and books. Balances are struck, and each item in the balance-sheet proved, and a written report upon each loan account, expressing the inspector's views regarding its condition and safety, forwarded to head office. This check, following upon the daily audit of the business maintained by the chief officers of the branch, leaves little room for clerical mistakes. The inspector's report, when it reaches head office, is studied by the superintendent of branches, and then placed before the general manager and the board. Bank inspectors in Canada must be men of exceptional intelligence, for they are required to visit branches thousands of miles removed from the head office, and in many cases theirs is the only independent opinion, other than the branch manager's, available for the chief executive officers regarding the business generally and the loan accounts. If the inspector is wise, he visits timber limits, factories, mills, mines, the fisheries, the warehouses, or the ranches of all important borrowers, so that he can form some idea of the practical working of the business which his bank is financing. If the inspector has superior intelligence, and his bank has branches extending from ocean to ocean, he should acquire an unequalled knowledge of his country, for it is obvious that he must travel ten to twenty, or even thirty thousand miles a year, in visiting the respective branches, and in doing so, meet at the hotels, clubs and private houses, and in the railway carriages and steamers, practically all the men of importance in every walk of life, and in every section of the community.

Customers' Balance-sheets.

An interesting contrast between the custom prevailing in this country and in Canada in dealing with commercial customers is that in the Dominion it is a *sine quâ non* that borrowers furnish their bankers with detailed information regarding their affairs, supplemented by a balance-sheet, copies of profit and loss accounts, etc., at least once a year. As my banking friends who are present are aware, a request for such data in England would in many cases be looked upon as semi-insulting. It is true that in old commercial centres such as this, trade is conducted upon more established lines, and I do not presume to criticise, but content myself

with stating that in Canada the practice is advantageous to bankers and customers alike—the latter finding in the former, as a result of his confidence, a guide, counsellor and friend. Divided bank accounts are rare in consequence.

Real Estate.

One of the wise provisions of the Canadian Bank Act is that banks are not permitted to lend on real estate, or upon the security of real estate mortgages. A bank may acquire real estate for its own use, or may hold and dispose of realty to secure a pre-existing debt, or may purchase under execution, etc., real estate of a debtor, but not otherwise, nor shall any bank, having acquired property in the method above indicated, hold it for more than seven years—*vide* Section 3 of the Bank Act. There has been at various periods in Canada's history, and there is now, much speculation in real estate, which would increase if the banks had the legal right to finance such operations.

Bank Failures.

We have bank failures in Canada, but they have not resulted from defects in our system, but from the lack of ability or the dishonesty of individuals, against which contingency completely effective safeguards are difficult to secure. Almost invariably it has been incompetence coupled with misadventure which has led to disaster. When collapse comes, it is usually found that false returns have been made to the Government, probably for a period of years. This experience is, of course, found in all countries — I have seen it stated that the accounts of the City of Glasgow Bank were falsified for five years prior to its failure. In Canada, swift justice is dealt out to the criminal—one general manager is only now completing a sentence of several years imprisonment, and another was sentenced to seven years within the last few months for making false returns to the Government. Altogether there have been nine Bank failures in twenty-two years, but they were all in the second or third rank as regards standing and size, and in no case have the note-holders suffered loss, while depositors have lost little.

Trained Bankers.

In Canada, as in this country, general managers and managers of banks are trained bankers, having invariably been engaged in their profession since their early youth. In the United States the opposite is frequently—in fact, usually—the case. I have known important executive heads of large American banking institutions who have spent the main portion of their lives in the profession of medicine or law, or in commercial pursuits.

General Managers.

In Canada the general manager is from circumstances somewhat of an autocrat—the Board of Directors rarely having among their number men with the time or banking training which would enable them to follow in detail the course of a bank's business. The Chairman or President does not, as in this country, devote his whole time to the conduct of the affairs of his bank, nor are there Executive Committees. The system has its advantages and disadvantages. Autocracy is a simple, safe, and effective form of government or administration, provided the autocrat is fully qualified for his great responsibility. In Canada we have been singularly fortunate in this respect.

Conclusion.

Assuming that I have convinced those present of the important part Canadian banks have played in the upbuilding of the Dominion, I should like to add that no section of the community appreciates more keenly the vital necessity of an uninterrupted flow of capital. American capital will be forthcoming, as in the past, for the development of private enterprise, and English money for such purposes will doubtless follow in ever-increasing volume, but the Federal Government, the Provincial Governments, the Municipalities and the great transportation companies, must be financed in London, and that is one reason why the safeguarding of the national credit of Canada in this —the greatest of all money markets—has been, is to-day, and will continue to be, one of the most important accepted duties and responsibilities of Canadian banks, and it also explains why wise Canadian bankers with branches in London have so persistently declined to stand sponsors to doubtful public emissions.

In the words of wisdom of Mr. R. B. Angus, who has had fifty-four years' banking experience in the Bank of Montreal, of which he is President:—

"Contributions through the Stock Exchanges and money markets of Europe to the financial enterprises of Canada have been extremely generous of late, and it is eminently desirable that the confidence thus displayed should not be abused. Some offerings have been made, it is feared, by over-sanguine promoters whose statements it would be hard to justify, and in relation to schemes where

the advantages to buyers are not quite apparent. It might be well to consider that, while money seeking investment is much more abundant in some countries than it is with us, there is seldom much lack of capital in Canada for participation in enterprises that are unquestionably sound. Our European friends might reflect that a home market, especially in the case of industrial securities, will generally furnish some indication of values."

In conclusion, may I, as a Canadian who has had the advantage of residing in the United States, and of knowing that country from end to end, who has enjoyed the inestimable privilege of living in this parent country, refer to the sub-conscious fear haunting every Englishman and pleasing dream of every American, that some day Canada will become part of the United States?

As one with an enormous acquaintance in Canada, and who has visited and re-visited every city, town and section of the community, I tell you with pride, my Lord Duke, my Lords, ladies and gentlemen, that I do not know one single Canadian who believes in such an eventuality, who harbours a thought so disloyal to our traditions, so contrary to our ambitions. Our earnest desire is to live on friendly terms with the United States, and to settle by arbitration any possible disputes that may arise, but our determination is to retain our political entity, and our anthem is now, and shall be in the ages to come, as it was in 1776, "God save the King!"

[Maps were kindly lent for the occasion by the European Traffic Manager, Grand Trunk Railway System, and by the General Passenger Manager, Allan Line Steamship Company, Limited.]

DISCUSSION.

The CHAIRMAN remarked that Mr. Williams Taylor had told a story of immense progress in banking business, founded, as he said, upon Scottish caution. His was a delightful tale of the conservatism, in its best sense, of Canadian banking. He thought one feature which illustrated the caution of the manager of the Bank of Montreal was that, although he had touched on every part of Canada, he had hardly mentioned the Porcupine district, where the discoveries of gold had lately excited the population of Ontario. He had been told that no one would look at silver there at the present time, thinking only of gold, although a few months ago he had received a solid brick of silver from that region, which was equal to anything that had ever been found in the States. Mr. Williams Taylor, however, had only mentioned the North Ontario mines in an incidental and passing manner, and had laid all stress on the banking system and the recent developments in east and west.

Lord STRATHCONA expressed his appreciation of Mr. Williams Taylor's paper. As a director of one of the principal banks of Canada for the last forty years, he knew something of the practical working of Canadian banks. He might mention, as confirming Mr. Williams Taylor's comparison of the banking system of Canada with that of the United States, that one of the ablest of the Secretaries of State of the United States had told him it would have saved America a great deal of financial trouble on several occasions if the Canadian system of banking had been adopted by the United States banks. He thought the Society was under a very great obligation to Mr. Williams Taylor for the care and consideration he had given to the subject.

Sir FELIX SCHUSTER said Mr. Williams Taylor had given such a glowing picture of the opportunities which Canadian bankers enjoyed that London bankers could not but look upon them with admiration, and with a certain amount of envy. He had rightly laid great stress on the commercial development of Canada, and emphasised the fact that commerce, itself based on agriculture, was the foundation of all banking. Where the opportunities of trade did not exist, banking could not be prosperous. On the other hand, banking to a great extent assisted the development of trade, and in that connection Canadian banks had been of the greatest service in developing the commerce of the country. Mr. Williams Taylor, in the first part of his paper, deprecated somewhat the theorist in banking, but, he (Sir Felix) thought, had disproved his own argument at the conclusion of the paper, which showed that he himself understood the theory of banking very thoroughly, and that the Bank of Montreal and other Canadian banks had worked on a sound banking doctrine. It was only by following that sound banking doctrine that they had been so prosperous. Canadian banks carried on their operations under a Bank Act, and practical bankers had no doubt been consulted in respect to that Act, who, if they had not mastered the banking theory to some extent, would not have been able to have drafted so successful a statute as the Bank Act of Canada had proved. He would like to ask Mr. Williams Taylor whether banknotes in Canada were legal tender all through the country. Could one bank pay their own banknotes by the notes of another bank, or had they to be redeemed in gold? The same question also applied to the notes issued by the Government. He had been much struck with the provisions laid down by the Canadian Bank Act, which regulated the securities on which a Canadian bank could make an advance. Such a system did not operate in any way in this country, where every bank regulated its own transactions according to what it thought was a

prudent and wise course. In Canada a bank could only lend on certain securities. He should like to ask whether the bank could advance money without security?

Mr. WILLIAMS TAYLOR replied in the affirmative.

Sir FELIX SCHUSTER (continuing) thought such a state of affairs was extremely curious; a banker could lend to a man without security, but could not lend on real estate. He thought the provision whereby a Canadian bank could not lend on real estate was an eminently wise one, and had no doubt saved the banks, and the country at large, from an excess of speculation in land, which was so often seen in other countries where rapid developments took place. On the whole, Mr. Williams Taylor was quite justified in being proud of the banking system of his country. He (Sir Felix) was sure that the Canadian bankers recognised their duty, and he did not believe that any unsound scheme would come from them to this country. A great responsibility rested on Canadian bankers, but he thought they were fully alive to it. In conclusion, he congratulated Mr. Williams Taylor on the wonderful progress of the Montreal Bank, and also on the marvellous development which all industries were making in Canada.

The Right Hon. Sir CHARLES TUPPER said, as a Canadian, he felt deeply indebted to Mr. Williams Taylor for his graphic statement of the past and present of Canada. He had been reminded by the paper of what had occurred some years ago at a time of great depression and stagnation of trade in the United States of America, when one of the most eminent men in that country drew the attention of the people to the fact that, while in the United States millions of people were suffering and 300 banking institutions had failed, in Canada not a single bank had failed, and the only way in which Canada seemed to be affected was by their contiguity to countries which were suffering as the United States were. He believed Mr. Williams Taylor's paper had, to a large extent, illustrated the cause of that, namely, that Canada had a better system of banking than the United States. It had been a great pleasure to him to notice the presence of his Grace the Duke of Argyll, under whom he had had the honour of serving as a Minister in Canada for several years. He should not be doing Canada justice if he did not say that among all the distinguished men who had represented the Sovereign in Canada, no one had discharged his duty more to the satisfaction of the Canadian people than his Grace. From the moment he first placed his foot in Canada, down to the present time, his Grace had never lost an opportunity of advancing the interests of Canada. As an illustration of the wonderful change which had taken place in that country, he might mention that in 1880, as Minister of Railways and Canals, he was pressing the construction of a line of railway from the Atlantic to the Pacific. Mr. Blake, one of the ablest and most distinguished men that the Liberal Party ever had at its head, and who then occupied the position of Leader of the Opposition, moved a resolution to prevent the railway from proceeding any further than the eastern side of the Rocky Mountains; and he might also mention that so distinguished a man as Sir Wilfrid Laurier voted for that resolution. On a subsequent occasion, in 1884, when the Canadian Pacific Railway Company were obstructed in obtaining means, either in this country or in the United States, for the development of their line, he was called upon to go to Canada to deal with the subject, and when he proposed that Canada should go the rescue, by a loan of thirty million dollars, Mr. Blake remarked: "Do not call it a loan; you know we shall never see a dollar of that money back." Nevertheless, the money was repaid within four years with interest, and he had lived to see the 100-dollar stock of that railway appreciate to 240. That was an illustration of the enormous progress Canada had made. As one of the men who had been engaged in laying the foundations deep and strong of the federation of Canada, which united the separate and scattered provinces under one, thereby preventing them falling like ripe plums into the adjoining Republic, he might say that one of the great objects which his colleagues and himself had in view was to hand down to their children's children, for all time, the great blessing of British institutions. He had no hesitation in saying that great as were their expectations at that time, they had been enormously surpassed by what had occurred. On the occasion when he had been called upon to open the Mechanics' Institute, in St. John's, New Brunswick, fifty-one years ago, he expressed the hope that he might live to see British North America united from sea to sea under one government, and presided over by a Prince of the blood. If he was spared a few months more, he would see that hope realised by the Government of Canada being handed over to H.R.H. the Duke of Connaught. Canada would expect a great deal from that distinguished gentleman, because she had enjoyed the inestimable pleasure, not only of being presided over by his Grace the Duke of Argyll, but by the Princess Louise, who won all hearts and led every Canadian to look forward with the greatest pride and pleasure to the continuance of Canada under the Government of the British Empire.

Lord BRASSEY, as an ardent well-wisher to Canada, said he had the greatest pleasure in moving a vote of thanks to Mr. Williams Taylor for his paper. It had been delightful to follow the glowing descriptions given by Mr. Williams Taylor and to fill up the picture with the intimate knowledge of an eye-witness. Canada was a country of magnificent resources, and it was fortunate for her that her banking system had been conducted under the rules, and in the sympathetic spirit, which had been described. The Bank of Montreal had been

singularly fortunate in including among those who had the custody of its interests Mr. Williams Taylor.

The Hon. J. L. GRIFFITHS (Consul-General of the United States), in seconding the vote of thanks, said the only cheerful thing he had discovered in the banking laws of Canada was the fact that bankers could loan without security. Notwithstanding all that had been said about the differences in the banking laws of the United States and Canada, it was reassuring to hear from Mr. Williams Taylor that there were two or three Canadian bank managers who were in solitary confinement at the present moment studying the provisions of the Canadian bank laws, which they, through oversight, had violated. It had been his pleasure some years ago to meet Mr. Williams Taylor. He then discovered that Mr. Williams Taylor was a typical banker. He had that air of aloofness which he (the speaker) had always found in approaching a banker. When he persuaded Mr. Williams Taylor that he did not want a loan on questionable security, he found him to be one of the most congenial of men. Mr. Williams Taylor's description of the progress of Canada had sounded more like a fairy tale than a record of actual happenings. He (the speaker) felt that the prosperity of Canada was due, not so much to the men who had come after, as to the early pioneers, the men who had endured sacrifices, and many of whom had experienced martyrdom to make Canada what it is to-day. He had been very much touched by the general expression of opinion that there was not the slightest possibility of the annexation of Canada by the United States. Such a thought had never been entertained in America, and as he had listened to what had been accomplished in Canada, he began to feel a slight apprehension that there might be sinister possibilities, deeply concealed in the minds of some Canadian statesmen, to annex his country, and he wished to enter his protest against any such project! He felt it was a great joy that the relations between the United States and Great Britain are as satisfactory as they are.

The vote of thanks was then put and carried.

Mr. WILLIAMS TAYLOR in reply, said he thanked the speakers for their very kind and complimentary remarks, quite as much as if they had been fully deserved. The presence of the Duke of Argyll further proved, if any proof were needed, his Grace's sustained interest in Canada, which had been such an intense gratification to the people of the Dominion. Many years had passed since his Grace had reigned at Rideau Hall, but time merely accentuated the affection and regard which he and Her Royal Highness the Princess Louise had won from Canadians under the Chairman's ever memorable and gracious administration. He also wished particularly to thank that great banking authority, Sir Felix Schuster, for the very kindly criticisms he had made, his fellow-province man, Sir Charles Tupper, and his friend, Mr. Griffiths, from the country beyond the Line, the virility and power of which had always filled him with profound awe.

TWENTY-SECOND ORDINARY MEETING.

Wednesday, May 24th, 1911; Sir ASTON WEBB, C.V.O., C.B., R.A., F.R.I.B.A., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Lambert, Thomas Stoddart, J.P., 7, Arlington-street, Wellington, New Zealand.

MacAllister, Edward B., Rockland, Maine, U.S.A.

Pan Wi Yan, 39, Heeren-street, Malacca, Straits Settlements.

The following candidates were balloted for and duly elected members of the Society:—

Côté, Thomas, International Waterways Commission (Canadian Section), Ottawa, Canada.

Fourie, Petrus Jacobus, Jansenville, Cape Colony, Union of South Africa.

Mott, Howard Schenck, 100, Broadway, New York City, U.S.A.

Piesse, Mrs. Adelaide E., Mountain Ash, Addlestone, Surrey.

The paper read was—

AMERICAN ARCHITECTURE.

By FRANK M. ANDREWS.

The art of architecture in any country finds a twofold source from the architectural tradition and the moral and intellectual character, political organisation, and mode of life of its people. To trace intelligently its development and artistic worth, these broad conditions must be accounted for.

Unlike the sister arts of painting, music, and sculpture, it cannot be detached from the masses, for it is not a creature of the museums or of the private collector, nor of the exclusive patronage of the favoured intellectual few, isolated as a thing apart, to be sought out and found in order to be felt and understood.

Contrary to these, it is the serviceable and intimate art of man, insistently a part of his familiar daily routine, a creature of his needs and circumstances, arousing in even the most heedless a consciousness of its existence and its power of expression either of beauty or of ugliness. For this reason, architecture artlessly

becomes an inevitable exponent of the characteristics of the people it serves, and the unerring index of their time and epoch.

The wisdom of the Greek philosopher was the intellectual flower of the human race, belonging to all mankind, but the architecture of Greece expressed the genius of the Greek alone, indicating the antecedents, environment, and soil which nourished and made possible the Greek philosopher. The Gothic cathedral, the feudal castle, the walled town, the monastery, and the vanished hovel of the common people told the story of mediæval times, of the great religious movement and the feudal system of the Dark Ages, with its cloistered learning, its strong arm of military and exclusive political might, and the subserviency of the masses. Again, the readjustment of these conditions, the resulting dissemination of learning, and the establishment of political and religious freedom, are faithfully reflected by the architectural development that kept pace with it throughout Europe.

In this brief allusion to a period momentous in its importance to the development and uplifting of the human race, I am touching upon matters entirely familiar to yourselves, yet which I wish to emphasise in order that you may appreciate that a discussion of American architecture must necessarily be approached with a similar regard for its political and civic development.

What I have to present to you deals with, perhaps, one hundred years of antecedent history, and does not exceed four decades of a subsequent movement that possesses any degree of architectural significance to others than ourselves. Yet as unerringly as in Europe we have recorded, in the terms of our art, the forward movement of our people.

Our land, colonised from England, Spain, France, and Holland, drawing to itself a population from most of the peoples of the globe—a land stretching from ocean to ocean, having climatic conditions ranging from those of Norway to those of Northern Africa—with its mineral, agricultural, and other natural resources sketched in with a broad and lavish hand, was in its inception and early history notable for its isolation. This isolation was not only geographical, but is reflected in a political system that is intensely and jealously individualistic, the keystone of its fabric being personal freedom and independence. As a new star in the firmament of government, it was peculiarly jealous of its own orbit, and largely justified its being by its very indifference to all European influence, fearing that therein lay discord and entanglements dangerous to the common welfare. Clearly the fundamental concept of this new government was the abandonment of the established European order of things, with its habits, customs, traditions, and conclusions, in so far as human determination could effect it. Pomp and display, class distinction and the exaltation by rank or otherwise of an individual or group, which in Europe played so important a *rôle* in the development of its civilisation, were not to find place in this new scheme of things, and, as a natural corollary to it, almost the entire vocabulary of architectural thought was automatically abandoned.

Therefore we find in early times but a trace of the interesting and inherent architectural beginnings such as were characteristic of Egypt, Greece, Rome, and the various European nations, nor do we find a place for a receptive disposition towards those architectural types which at that time prevailed throughout Europe, as its expression of the power and importance of government or of a class.

A timid concession to traditions, which could not be altogether denied, we find reasonably applied to the first structure of the national capital and in the executive mansion at Washington. These structures owed their existence and excellence to the interest of Washington, Jefferson and Hamilton, the locating of the capital itself giving to our most important architectural effort of the time a personal significance, corresponding to their influence in the affairs of our Government. Throughout the Colonial period we find in New England and in Virginia, with its sister States, a faithful adherence to the manners and customs of the Mother Country, its architecture consequently that of the coincident Georgian period of England, and the word for it in our architectural vernacular, "Colonial." With us an architecture of brick and wood, severe, simple, and with a certain refined stateliness, owing its existence as a precedent to the influence of our then leaders of thought and action, and merely reflecting their point of view, it ultimately became only a mode or habit of construction without architectural force or vitality. Its earliest and best examples, preserved by a fortuitous circumstance throughout a century of neglect and indifference, became in the end a helpful educational influence pointing towards the true path of artistic excellence; a cudgel with which to belabour a heedless utilitarian public but too prone to an inartistic

display of its swiftly-acquired wealth, and to awaken its artistic conscience.

Again we rediscovered the rare beauty, quiet strength, and world of suggestion in the old Spanish missions of southern California and the south-west. Glowing with artistic spirit, in their extreme isolation from the then civilised world, they seem a miracle of accomplishment. They are the product of minds who loved art, and remembered it as of the land of their birth; but, forced by environment and conditions to a fortunate simplicity, they preserved and created for the admiration of our future generations the essence of all that is good in the architecture of Spain. To-day this work is a powerful source of inspiration to the prosperous people of all that region of the United States where these good old mission fathers did their work of civilisation, leaving behind them evidence of their love of the beautiful. These then were the slender links that united us with the ancient architectural forms, and while they were not inherent nor endowed with a spontaneous expression of ourselves, nor an indication of our future development, they for the moment served as a borrowed garment, fortunately a good one.

The story of our departure from these standards, and the subsequent period of artistic squalor and ignorance, which I may refer to as our architectural Dark Ages, was one, however, not of wilful ignorance nor purposeful neglect, but of a condition.

It is the story of these people isolated by a great ocean, and by the greater intellectual ocean of abandonment of European traditions and ties; with the great task of solving an experiment in Government on a huge scale; with a vast wilderness to subdue and render serviceable to man; with the problem of assimilation of an influx of foreign population possessed of alien thoughts and customs; of a country that, as a whole, may be likened to the pioneer settler whose log-cabin is reared quickly out of the immediate material at hand for convenience and shelter only, so that he may the sooner set about the task of clearing his land and gaining his livelihood. Should accumulated wealth later bestow upon him or succeeding generations its independence of labour, and the opportunity to cultivate the mind, he may then observe the stored wisdom of history, and bow to its influence and tradition.

Therefore in our country, in this condition to which I have likened it, we find the Colonial type of domestic architecture principally interpreted, not by architects nor under an artistic impulse, but by the builders of the period whose personal vagaries and idiosyncracies more and more overwhelm the meagre examples of this authoritative style. Throughout the country, and for the greater part of the nineteenth century, these conditions prevailed, for we cannot take as essentially typical the attenuated architectural movement, if it may be so described, that was discernible in a few of our more important sea-board cities. Broadly speaking, the entire scheme of things involved no application of artistic code or principle, but was merely the product of the builder-craftsman. In the older portions of the country we find the more important structures reared of brick and stone with a generally prevalent application of our own peculiar system of wood-construction to domestic requirements. Throughout the middle west, in Ohio, Michigan, Indiana, Illinois, Wisconsin, and all that region west of the Mississippi River, the saw-mill was king and the carpenter-builder its faithful apostle and exemplar. The strictly utilitarian held sway, and the rapidly-increasing population of this region had neither the time nor inclination to consider such matters as art nor the refinements of a wealthy and settled community, and thus there became impressed an habitual habit of thought, which stood for years as an obstacle to artistic growth and development. Buildings were an object of pride, and aroused interest and appreciation only because they expressed in size, in materials employed, and in numbers, the growth of a community or the prosperity of the individual. These structures, with here and there a reminiscent architectural, detail, usually crude and illiterate, were devoid of architectural sense or meaning, as were the people themselves of a proper understanding of the codified systems of artistic thought.

In this connection it does not appear to me that it is logical or permissible to trace the course of that spark of architectural knowledge which moved onward from the early Colonial days, revealing itself from time to time in isolated instances throughout this period, and claim that its description is the story of American architecture.

Personally, I prefer to deal with that which in its broader sense arises from the people, as with the seed that is sown with Nature's forces working invisibly and within, until, under favouring conditions, its growth and full flower appear. Despite their apparent indifference to artistic feeling and their devotion to material

development, these people held within them the seed of art, and during this period its germination and hidden growth was sure, awaiting! but the bursting of a materialistic, envelope to blossom into a keen love for, and appraisal of, the value of beauty and art to mankind. Manifestly this must be true of them since there were no kings, nobles nor courts to patronise the arts, no leaders of thought who could arbitrarily establish an artistic movement. The accomplishment of this could only be through the gradual dissemination of knowledge of, and love for, the beautiful throughout a people concentrated on practical problems, until they, in a unity of thought and action, should respond to the resulting impulse, thereby making possible an architectural epoch in their history.

It must be borne in mind that we are dealing with the development of architecture within a democracy, describing a movement probably without a parallel in the history of the art. Republican Venice in its day of commercial supremacy had her traditions of Rome and Greece, an old order of things to build upon, and an unavoidably inherited environment not of its own creation; of an artistic bequest authoritative in its derivation, and certain of itself.

We are dealing with a nation in which no individual could so dominate as to become a mainspring of artistic action, a nation so wedded to the formula of democratic simplicity that he who would lead must become its consistent votary, a nation that expressed this habitual attitude architecturally by its wholesale neglect of the artistic excellence of its public buildings of this period.

Passing over the time of the Civil War, the reconstruction days and the panic of 1873, we find architecture at its lowest ebb concurrently with the renewal of the energetic development of railroads and of other fundamental industries, a consequent rapid increase in accumulated wealth, and of the power of the individual as well as of communities to assert their importance by a material display. The individual respected no architectural authority, save that of his own taste, under the guiding influence of the carpenter-builder. The architect was a negligible quantity, a mere speck in the background; and, in fact, the name had small significance except only when applied to the builder. An architect was a dubious being at best, who insistently expounded impracticable and useless theories about art and other effete things of European origin that were quite inimical to the interests of the local dealers, building trades, and their political henchmen. These were the controlling influences, and this was the day of diluted Eastlake and whimsical variations of Victorian Gothic, of jig-saw ornament, and of cast-iron tortured into nightmare semblances that to this day can scarcely be traced to their remote ancestry even by an expert. Under this authority, and with this vernacular, the residential architecture of the time was created, and cities and states so announced their power and importance in their institutions of learning, their capitols, courthouses and other public structures.

Thus we have before us the spectacle of democracy, with its growing newly-acquired wealth and leisure, embarking without rudder or compass to range aimlessly the broad unfamiliar stream of traditional art. Many souvenirs of this extraordinary excursion still remain with us, but, fortunately, the greater portion of the work of that day has vanished to make way for better things. The climax of this era occurred in the Exhibition buildings in 1876 in Philadelphia, and the greater part of the succeeding decade was required to mark its fall.

As a youth, the writer witnessed the fullness and the decline of this period, the beginning of the reform movement, the rising appreciation of proper standards, the sure but slow education of popular interest and taste, until to-day it may be justly claimed that the fundamental elements of our peculiar American type of architectural expression are discernible. Its precise formulation may not yet be possible, but it is a vital and growing thing, plastic, perhaps restless and unsettled, yet reflecting our rapidly-crystallising characteristics as a people. As an art, it has unquestionably found itself, and its underlying purposes and tendencies are capable of analysis and discussion. In method it is bound to no exact tradition nor architectural style, but does acknowledge the underlying principles and authoritative precedents that energise them all. For the present it is transitional in character, and, as to detail, is essentially an architecture of adaptation, wedded, as I have said, to no particular style, but seizing for the purpose at hand any suitable architectural form that applies to our situation and environment, and controlled by a trained art intelligence.

The thin skirmish-line of architects—which stretched across this artistic wilderness from the century of Bulfinch, Hogan, L'Enfant, and

others, to the century of Hunt, Root, Richardson, and their contemporaries, men who bravely maintained their loyalty to artistic purity, and devoted pursuit of art under all discouragement—has now broadened into an army of architects and artists, the product of schools of art and architecture both at home and abroad. These men are inspired by exceptional opportunity and an appreciative public. In their numbers, and the power of their collective influence upon the civilisation and development of their country, they exceed that of any similar group of men of a single generation to be found in any recorded period of the world's art development.

Here, then, we have the interesting example of an art movement rather typically American, wherein the love of the beautiful and the desire for its intelligent expression is not due to the stimulus of the patron towards the artist, but on the contrary has flowed from the artist to the patron, or rather, from an entire group of artists to an awakening public. Democracy having solved its fundamental problems, now encourages intellectual and artistic growth with a lavish patronage, that in its aggregate volume and result will some day be viewed with deep interest by the world at large. Even from the standpoint of historical analogy, the forces are at work and the material exists out of which to fashion this result.

The entire material equipment of this country which served its purpose throughout a period of transition and development must be, and is being recreated in permanent and enduring form, thereby affording an extraordinary volume of architectural opportunity. A practical people, accustomed to quickly grasping and solving broad problems by concerted action, they have realised that beauty and art are vitally important things, and that to be acquired as a national asset their guidance and direction must be assigned to that group of men whose training and experience entitle them to it, and whose active propaganda are but reflected by this conclusion.

The educational influence now at work within us is as wide as the nation itself, proceeding primarily from the group of men referred to, also from schools of art, which are to be found in every important city in the land, from the regularly-established schools of architecture in our various colleges and universities, from the active and alert efforts of the lay press, and the intelligent and interesting art-criticism and discussion of the popular magazines and the technical journals of the profession.

In this scheme of education Europe may be regarded as one great laboratory, in which the practical application of the theories and influence of this educational movement are tested and applied. The thousands of Americans who, year by year, cross the Atlantic and travel about Europe have, regardless of their immediate motive, both consciously and unconsciously, absorbed the spirit, the grandeur and nobility of its artistic achievements, and have at last perceived that, besides the material wealth of a country, there must be a spiritual and intellectual wealth which art alone can express, and without which no nation can be truly great nor the full fruition of a people's destiny be accomplished.

I believe that these influences have resulted in a public sense of discrimination and a sound professional analysis of the art and artistic influence of Europe, and from this I reason that there will ultimately appear in America a characteristic American style that will be grounded upon the varieties of architecture, sincerely expressing the organism, use and purposes of our structures, yet not insisting upon the forced and unnatural adaptation of motifs and detail in archæological reproduction of other styles not suited to ourselves. The day has passed in my country when the ideas and so-called originality of the individual are to be tolerated as a worthy substitute for the time-honoured forms and concrete conclusions which represent the cumulative authority of the many minds of the past striving for truth and beauty of expression.

That our growth and development will be to a large degree homogeneous, is to be expected, because of the ease of intercommunication and consequent habit of travel between our various states and cities. While interesting variants may appear, due to the Colonial influence of which I have spoken, there will be none of those phenomena that have in the past arisen from restricted intercommunication, isolation of cities, division of languages and customs which so strongly individualised and restricted the art and thought of European groups, and which so comprehensively affected the formation of its various styles of architecture. Speaking one language, and existing under one government, with facile and established habit of intercommunication, we are not subject to, in any given locality, the possible provincial outlook nor the requirements of local materials or customs peculiar to that locality, as is the case in Europe.

Undoubtedly the greatest, if not the primary, stimulus of the present artistic development of the United States is to be found in the Columbian Exposition of 1893 in Chicago. It was here that the profession for the first time found itself in possession of a theme monumental in its scope and dignity, and of that peculiar quality and complexity which put it beyond the capacity of the layman or of the builder to control; resulting, therefore, in its assignment to a profession now become powerful enough to assert its right to assume direction within its own domain. The initial moment in our art history that required the united action of a group of properly-trained men, it was the first time when they had to deal with a problem in which architecture was the dominant note; recognised as the visible and vitally-important expression of the dignity and scope of the enterprise. The interest of a great public was to be aroused, and a situation of charm and beauty was to be created as a functional part of the display itself, and for this purpose the business men in charge perceived that good architecture was indeed a practical necessity. For the first time the ability of architects accustomed only to separate individual effort was to be gathered together, synchronised and welded into unified action, wherein the individual tendency must be subordinated to the requirements of all while dealing with a grandiose plan, the grouping of buildings in harmony of mass and outline conforming to a central governing ideal.

For the first time on American soil there was to be produced in orderly triumph the majestic splendour of ancient Rome, of Italy, of the dreams of France, and these architects, recruited from the field of conventional daily routine, thus found in their grasp the opportunity to display to a great people the possibilities and meaning of the art of architecture.

To-day it is a thing of the past, ephemeral in its material existence, but everlasting in its message and impression upon the nation. With difficulty can you, to whom the traditions of your own land and the storied riches of Europe are familiar things, realise the revelation contained in this work of art, and its stimulus to our people.

Its direct influence is manifest in every important city of our land, by local agitation for civic beauty, by established and projected control, and direction of the art expression of individual enterprises by the popular demand for the beautifying of streets, the monumental groupings of public buildings, and the constantly increasing intelligence of popular architectural criticism.

A hitherto unknown language to the masses, this enterprise aroused in them a spirit of inquiry and appreciation, that with one great sweep of thought elevated the profession of the artist and architect into a plane of equality with all of the utilitarian pursuits of a practical money-getting age. With a public thus instructed, characteristically eager to inform itself of new thoughts and ideas, we find a typical response thereto through the columns of the daily press, the advertising of the Fair itself, and the pages of our popular magazines.

Alert in their department of public activity, they were keenly alive to this demand for knowledge, and, in turning over the files of the popular prints of the day, one may be surprised at the volume and importance accorded to this subject. For the first time the profession found itself a firmly-established part of the general scheme of things, a factor of public interest, upon which rested the responsibility of interpreting the intellectual and material growth of a community while subjected to intelligent scrutiny and analysis of its work, and in a position to deal successfully with the influence of ignorant Philistinism.

These people of practical and materialistic habit of thought responded promptly to the realisation that here indeed was a new field of development, that paid big dividends in its effect upon the physical and moral welfare of both the present and future generations.

Search as you may the current files of thirty years ago of the press of any community in our land, and no reference will be found therein to architecture or any other art as being of public import or interest. To-day our important metropolitan newspapers maintain a regularly-established department devoted to illustration and comment upon the current architectural products of their vicinity, and the newspapers of the smaller cities display a keen interest in their local art movements.

To me this is a fact of deep significance, knowing as I do the power of the public press in our land, which not only leads and formulates, but likewise reflects public opinion. From this awakened artistic consciousness, no longer concerned with art as an abstract question but as a matter of practical importance, there arises a stimulus which imposes upon each architect, when dealing with an important project, a responsibility so seriously involving his own

personal prestige as to remove him from the field of irresponsible effort. Our building regulations and various movements towards the establishment of art commissions as a part of the organisation of city, state and national government, are effective in their way and undoubtedly important, but the final authority rests with an enlightened public opinion which is the product of the influences to which I have alluded.

While according to these influences their general force and direction, I cannot altogether subscribe to the characteristic attitude of the writers of books and essays about art as they apply it to architectural discussion.

We who have to deal with the everyday conditions of our art, and live with it constantly, know that our feet are mired in the clay of practical, materialistic, and unlovely things, which cannot be tossed aside like the painter's canvas, nor the sculptor's sketch, if we find our artistic progress impeded.

Our ability to apply our art, knowledge, and skill to these things should be, in a large measure, taken as a matter of course, and—like the ability to play the piano which a composer must obviously possess—a means to an end, in our case too often overwhelmingly utilitarian.

Those who review our work for literary purposes generally fail to penetrate this realm of professional routine and practical impedimenta, and we find them wandering about in the abstract discussions of the studios, arriving nowhere, and quite as apt to be of harmful influence as otherwise.

It is my purpose, therefore, to discuss our contemporaneous work from this perhaps unimaginative and realistic standpoint, as being essential to a correct conception of an important factor in the moulding and the formation of a typical American architecture, and without which it cannot be truly appreciated nor understood.

I love to soar to the heights with an imaginative writer when addressing himself to our stubbornly practical art, for it does us both good, but unless he belongs to the Brotherhood, and, like myself, has to get back to earth again, the return trip becomes rather lonesome, particularly when I find myself humbly surveying a lot of actualities that have not been with me on the voyage. I believe that these actualities, that are our common fate and with us every day, are unitedly a component force reacting upon our artistic desire and instinct, which will finally produce a resultant force that may become differentiated as an American style. Of these two forces the artistic theory has been pretty thoroughly exploited, but I believe that the workings of the force, which I term "actualities," should be accorded equally prominent attention. As to the resultant force, have we now in America, that formulated habitual expression of feeling and characteristic assemblage of detailed forms —a vernacular if you please—or an evolved system of massing, grouping of parts, or of proportion having a sufficient individualism of our own, to be designated as an American style? Obviously, this resultant does not yet exist, and indeed may be a creature of very slow growth, but it certainly is in the making.

In the buildings erected during the past twenty-five years, we have run the gamut of practically all known architectural thought—have experimented with about everything this side of the Indian wigwam. This has been done, not because of any lack of inventiveness on our part, nor of imagination, nor again does it suggest any feeling of satisfaction with such a state of affairs. We realise that we are dealing with something much more important than passing fads in millinery, automobiles, or dress, and that eventually this indiscriminate borrowing of other people's architectural garments must be succeeded by a costume more fittingly our own.

Considering, however, the prevailing circumstances surrounding our profession throughout this period, it becomes immediately apparent that my previous observation is reasonable concerning the causative action of our practical "actualities."

The incredibly rapid growth of our cities, increase of population, the demand for a new equipment of buildings of every variety of use and purpose, the razing of existing buildings, products perhaps of a previous decade, but become obsolete and in the way of imperative necessities, constituted a movement of such overwhelming volume, to be accomplished in such a short space of time, as to crowd upon the shoulders of one generation of architects—who virtually at the same time were recreating themselves — a variety and volume of new problems, complicated in their every practical aspect, and presenting an entirely new artistic field of attack, that perhaps would not have been an easy task for three generations of men well intrenched amidst familiar traditions.

Again, the entire absence of suitable precedent or style, and the presence of a prevailing and

entirely new form of construction having no European prototype, obviously presented a free range for the exercise of individual fancy, resulting ofttimes in incongruity and an inharmonious eccentricity and lack of restraint. Owing to the ever-increasing height and the form of our buildings—a subject of great importance to which I shall give special attention —new problems in the scale and application of detail were presented, which resulted in many architectural catastrophes, but are now better understood.

Owing to all of these conditions the successful architect found himself burdened with an extraordinary and varied assortment of buildings difficult to deal with at one and the same time, with the demon of American rush-methods relentlessly pursuing him—regarded by all of our highly-organised and efficient building trades as a sort of human rubber-stamp that worked automatically — what else could he do but throw up his hands in despair, with one backward look of envy towards the old monks who constructed a few feet of cathedral in a generation, turn archeologist, and plaster his steel skeleton with a tidy arrangement of architectural dope, calculated to soothe the owner, the public and the contractor, making everybody perfectly happy, but the poor architect left alone with his sadly disfigured ideals?

It is my personal belief that this has had much to do with the exploitation of certain historical styles by several of our notable architects; to the extent that their names have become synonymous with those styles, as, for example, Richardson with the French Romanesque.

It is an undertaking that requires no small amount of executive ability, and a highly-organised office successfully to manage this condition, and whatever tends to standardise and unify its efficiency must perforce be found and used.

Richardson, with his masterly knowledge of the style, was quite justified in his adherence to the Romanesque. It was not too violent a departure from the prevailing mode, was easily managed by the building trades, and suitable to the then existing range of available building material. How clearly he perceived this is proved not only by his own work and by that of his immediate successors, who were trained under him, but also by the complete collapse of the movement he established when it fell into the hands of the horde of imitators who neither saw nor appreciated the importance of this fact, and who, in attempting novelties of treatment without proper means at hand, helped it to an early death.

Our next important architectural revelation fared more fortunately by proving itself much more adaptable to our wants, and, dealing with an almost infinite variety of refined flexible forms easily applied, became the reigning fashion for an extended period, and is to-day reasserting itself in a salutary and refreshing way.

This revelation came through the work of White and of MacKim, who did not at first display a full mastery of the style, but temporised with a curiously interesting architecture of brick and reserved application of Italian detail. They soon became the leading exponents of the Italian Renaissance, and since their output of residential, commercial, and other classes of work, was enormous, its educational influence with us must be counted of prime importance, and by their own good taste, fine sense of proportion, and full appreciation of the refinements of the style, they elevated our standards to a plane that will not be abandoned. In their extensive use of the Georgian period they reminded us of our own best tradition, showed us the value of simplicity, control of expression, and respect for architectural law and order. Office expediency is to me apparent in much of their work, particularly in their bold confiscation of entire architectural compositions, as for example, in the Tower of Madison Square Garden.

With us the first important exponent of the modern French school of thought and design was Richard Hunt, and his work was of such volume, his clientele so important, as to place him as one of the factors that shaped our tendencies. His earlier work adhered closely to the contemporaneous French Renaissance, but later his frequent and facile application of the style of Francis I. to noteworthy structures produced a widespread interest in the style. His high place is accorded him, not only because of the importance and quality of his work, but also for his sturdy maintenance of the best traditions of the French school, which now have become so important to us.

These men were great artists whose inspiration, given to the young men of their day, now become the active men of this day, and to the whole trend of architectural thought in the official, governmental and private life of our country, cannot be overestimated.

It is important that I refer to the aims, influence, and results of the system of

architectural education prevailing in our colleges at home and of the foreign schools, notably that of the Beaux Arts of France. Our courses are largely influenced by the Beaux Arts system of instruction, and the theory of architectural training as formulated by it. Better than any other, it seems to us to concern itself with the broad principles of architecture, of the laws of composition, mass and proportion, the proper use of ornament, and emphasises the comprehensive grasp of problems of a nature comparable to our own. Furthermore, it has evolved a technical method of expressing these things so intelligibly that it is peculiarly suitable to the student, first grounding him in principles and then developing in him the power to individualise his interpretation of them. It is this insistency upon principles, and freedom from exploitation of any particular style or fad and the resulting flexibility, which popularises this school of training with us. The general result of this organised system of education is already apparent, and will, in our succeeding architectural generation, mark the greatest forward step in the right direction that we have yet known. Already the sobering influence of logical thought based upon this training in principles is visibly impressing itself upon our buildings, to their infinite betterment, and revealing a firmness of touch and a sure handling of design. There is forming a unanimity or trend of thought that is replacing the scattered individual assertiveness of style that was characteristic of former days, which presages a typical American mode that will continue and prevail as a foundation for consistent development. I believe that the English influence and traditions will be always more in evidence in our expression of domestic architecture, because our habits of living are modelled upon the English customs, with particular reference to country life. Our public buildings, and our disposition of the larger civic architectural problem, will undoubtedly exhibit more decidedly than ever the French influence and system.

In the field of commercial buildings, we have presented to us our own peculiar characteristic American problem, and out of it we are developing our own positive contribution to architectural form.

Unlike the Gothic architecture, with its organic union of construction and design, it partakes of one characteristic Gothic quality, namely, the emphasis of the vertical and subordination of the horizontal line in composition. But again, it requires a superficial envelope, a simulacrum inclosing and concealing the real structural elements beneath, and in this respect becomes analogous to the arcuated construction of the Romans with its outward application of Greek forms and orders.

That we should have indulged in architectural flounderings and fantasies with such a problem as this to deal with is not to be wondered at when all things are taken into consideration.

Our most unruly problem, the tall building, is, from my way of thinking, the result of the logical working of the law of supply and demand. It is neither fantastic, avoidable nor useless, nor will it yield to adverse legislation, because public necessity formulates a public opinion that will not legislate.

It is amusing to read in the publications of fifteen years ago the diatribes against it and prophecies of its early extinction which were provoked by the modest fifteen and twenty-storey structures of that time. The architect of the then tallest building in New York announced in print his belief that the end of tall buildings was in sight. Structures of twenty-five, thirty, forty, and even more than fifty storeys have been the answer. It furnishes a typical example of practical necessity and mode of existence creating a movement which ends in something distinctively characteristic of a people, and in this instance steel-construction and the tall building is affecting us as did the round arch and vault of the Romans. The business centres of such cities as New York and Chicago, as created to meet the conditions of 1860 to 1870, were soon outgrown, and the necessity for larger and better buildings became apparent. The established business centres could not be, or at least were not, moved, property values and the existing inter-relations in those centres being of too great moment at the time.

This generally prevalent condition produced different immediate results in different sections of the country, which long since have converged into an established common practice.

In Chicago, we find that the direct causes that led to the first example of true skeleton construction were (*a*) the necessity for increased height; (*b*) which the character of the supporting soil rendered impossible on account of the weight of the then prevailing type of massive masonry walls and interior columns, and which could not be overcome unless (*c*) a system of construction be devised stronger and of less weight than other types, which was

accomplished by the device designated by us as the "Skeleton Steel Construction."

Had this been the only merit possessed by this type, it might have remained a localism of Chicago, or at least it would not have become the highly organised, complex, and widely adopted construction that it is to-day, practically amounting to our accepted type for commercial purposes.

The system, as developed, is a simple one in principle, consisting of supporting columns of steel or cast-iron, braced in all directions and riveted or bolted to the horizontal girders and beams, which not only support the floor construction but, more important still, also carry, storey by storey, the outer walls of the structure, which thus cease to have constructive value, becoming a thin screen of material that serves to enclose the building and to protect the steel fabric from exposure.

The outer walls being but screens, the masonry supporting nothing, their piers were in consequence easily reducible to a minimum surface width and the area of glass could thus be largely increased, thereby giving a maximum lighting to the interior, a device rendered necessary by the generally increased height of our buildings fronting upon streets that could not be increased in width. The effect of this condition is manifest in the earlier treatment of the architectural design of these structures and has become typical of them in the work of the present day.

The walls, being non-supporting, could be reduced to a minimum thickness, thus providing an important addition to the interior area of each floor, and materially increasing the earning power of the building; an imperative necessity because of the rapid rise in ground value in central business districts.

None of this development would have been possible, however, if it had not been for the American type of elevator, which was promptly developed in response to this new demand, and has kept pace with it ever since by evolving new principles of construction and operation necessary to cope with the constantly-increasing height of buildings and the enormous increase in service both as to speed and volume of traffic.

These foregoing advantages, meeting our conditions and requirements, led to the general widespread adoption of this system, resulting in the development of remarkable contracting and building skill and organisation, of which we have every right to be proud, and which has produced amazing results as to speed of construction, quality of work, and economy. With our high ground values and the necessarily great earning power of these structures, the saving of time in their erection became a matter of momentous importance, and this necessity led to the creation of the skill and organisation referred to.

This type has come to stay because of its attributes of structural endurance, safety, economy in first cost and of upkeep, and its general suitability to our modern conditions.

While it has belonged to the domain of the architect, becoming the accepted type for our huge hotels, apartment houses, and commercial structures, and under his direction is fast becoming a thing of grace and beauty from a beginning of sprawling ugliness, nevertheless it must be said in all fairness that these structures could not have been devised without the skill and genius of our mechanical and structural engineering professions, the builders and the skilled mechanics, whose trades have become specialised and developed by this demand, all united in effective co-operation with the architect.

The question is frequently propounded: "Are these structures beautiful, or can they be made so, and thus enter the realm of artistic thought?" In my opinion the answer is emphatically, yes. It is no conclusive argument to decry them because in certain communities people live and pursue their vocations in such a manner as to make this type of building unnecessary, or because, since they have thereby been enabled to restrict the height of all building to a lower level, producing a uniformity of general effect, they can then point to Paris as the grand example of this sort of thing, and claim her artistic virtue as their own. Beauty of this sort is the outgrowth of suitability to local conditions, plus the artistic thought that may be apparent in the means adopted, but it is, after all, only one kind of beauty. There is beyond question the beauty to be found in truthful picturesqueness, when it is a natural outgrowth of conditions inherent in the people, and it can be made quite as respectful of architectural law, and the result of individual effort being made with regard to the effect of the whole, while working in this freedom of spirit, as though it were hemmed in by ironclad restrictions as to height, etc., that are characteristic of certain communities.

The development of the exterior treatment of the tall building, architecturally, has been

exceedingly interesting, and in the time and space afforded to me in this discussion cannot be described in detail. The stereoptical views, and the comment thereon, which I have to present, will illustrate the subject in a more effective manner.

Briefly stated, our fundamental principle in design seems to have become established by treating the tall structure as a column with its base, shaft and capital. In all of the best and most pleasing examples of the later work this element appears, and we find the lower storeys grouped in a single architectural composition supporting a long vertical and shaft-like series of storeys grouped into a simple treatment that carries the eye upward without interruption to the crowning feature of the entire design, which again is a series of storeys combined into the capital, as it were, of the mass. The pleasing variety of thought in the handling of this scheme of treatment is one of the best features, and generally speaking is now characterised by a sober refined self-control and a truly architectural spirit. In the classic feeling of the Italian Renaissance, the municipal building of New York is unquestionably one of the best solutions of the problem on these lines that we have, while in the West Street building and in the Woolworth building, both in New York, we have equally good examples of the application of Gothic feeling and detail. Considering its extraordinary height and unusual mass, the design of the Woolworth building is in my judgment an architectural achievement of the highest order. I have referred to these buildings not only because of their architectural merit, but also for the reason that they represent the two broad schools of design which seem most suitable to the problem presented by the tall building, and are, I believe, typically representative of our lines of future development.

In pointing out the consummation of this century and a half of architectural growth in my country, I would have you enter the harbour of the city of New York on a trans-Atlantic liner, and from that point of view for the first time observe the buildings of the lower end of Manhattan Island with their towering and amazing sky-line and mountain-like mass of architectural grouping, picturesquely artistic and truthfully expressive of the spirit of our lives and activities.

I believe that it will grip the imagination of any observer, whether he sees it for the first or the hundredth time, and that he will experience from it that flow of thought and impression which is produced only in the presence of some great and inspiring thing. To me it illustrates the quality and the character of our people, their aspirations, and their peculiar genius in terms of architecture, as do our mountains and valleys, our lakes and rivers, the physical character of our land. Prosperity, wealth, and power we are surely possessed of, and we are as surely acquiring from the artistic wisdom and traditions of Europe that which is useful and good for us to have, and are applying it intelligently to our needs. As a people we are learning to respect and revere Art, and to value its uplifting influence, and with these fundamentals to build upon, and with the artistic forces that are ever active amongst us, the future of American architecture will be worthy of high regard.

DISCUSSION.

The CHAIRMAN said those present would agree that Mr. Andrews had delivered an absorbingly interesting paper on American architecture. It was wonderful to reflect that, as he had said, in 1873–4 the Americans were still without any manner of their own, or any decided leanings, in architectural design, so that in the last forty years they had developed the wonderful work which had been illustrated on the screen. When he came to the meeting he thought he knew something about American architecture, but he now found that he was altogether out of date; three or four years had elapsed since he was there, and that was a long time. The tall buildings of that date had been eclipsed, and the 700-ft. buildings had been erected since he was there. When he was in New York he did not think the American architects were themselves quite sure as to the possible final success of those buildings, and they were always asking Europeans what they thought of them. He never felt any hesitation in declaring that he thought them extremely fine, though he believed the Americans to whom he said it sometimes thought he was chaffing them. The effect of them upon him was very strong; and when the streets were fuller of them, and there was an aspect of greater cohesiveness, the effect would be better still. But when he was there, the tall buildings were only occasional, so that the effect was somewhat "jumpy." Looking down town in New York at that date reminded him very greatly of the streets of Genoa and of other of the older Italian towns. The New York streets were wider, but the buildings being higher, with the overhanging cornices, there was produced the same effect of deep shade at the bottom, and brilliant light on top. Fine as one thought such buildings out there, he did not think our admiration for them would enable us to imitate them in England

—our atmosphere and our requirements seemed so different. But it was important to note how keen was the interest taken by the American public in matters architectural. Here the public did not generally take much interest in those matters, and the reason might be that Americans had had that new problem to solve. Our problems had been settled, and most excellently, in days gone by, and at present we were somewhat nervous about trying new ones. In America architecture was a topic of public conversation, and one could hear comments upon the beauty of design of the buildings. That was, naturally a great encouragement to the artists working in brick and stone, an advantage which Britishers congratulated them upon possessing. Another advantage was the unified action in that country; they were all working on the same lines there, though not necessarily on the same style; sometimes they used the Gothic, sometimes the classic; but the buildings were so huge that the detail in them was a comparatively small matter. The buildings were designed with the idea of great effect, a great base, a great shaft, and a great cap; and each was trying to bring about the same effect in his own individual way. That was an advantage which was seen in all countries in the world in the matter of architecture. In Greece, for instance, they worked together on the same lines, and they achieved success; and so in Rome, and in the Renaissance and in the English Gothic. When working together with the same aims, success followed, which showed that architecture was an associated art, and that a Copyright Bill was scarcely necessary or desirable for architects. What was required was that they should assist one another by their examples, and thus by degrees develop something which should be not only satisfactory to themselves, but should bring honour and repute to the countries in which the buildings were placed. The history of our country was largely built in its architecture; and the history of America was now, he thought, being largely, nobly and grandly built by American architects. He was, therefore, sure that the meeting would join with him in congratulating Mr. Andrews and the American people on the magnificent opportunity they had had. He knew very well Mr. MacKim, of the firm of MacKim, Mead and White, one of the most charming men who ever stepped, as well as one of the most modest and refined. When he (Sir Aston) was in New York, Mr. MacKim had just finished the library for Mr. Pierpont Morgan, one of the most refined buildings, of ordinary size, which he had ever seen. A New York City man told him that constantly on going down town he went out of his way for the pleasure of going down the street to look at the elevation of that library—a very strong illustration of the effect which architecture might have upon the individual. He also had the pleasure of knowing Mr. Cass Gilbert, whose very fine buildings the lecturer showed on the screen. Mr. Gilbert was also a great artist and a most delightful man. There was one omission in the slides, and that was an indication of what buildings were designed by Mr. Andrews himself. If he showed any of them, he did not say which they were, a piece of information he was sure they would be glad to have.

Mr. H. H. Statham, F.R.I.B.A., cordially supported the expression of thanks to Mr. Andrews for his interesting paper and pictures. He had received new light that evening on the conditions of American architecture, because although he knew the position of Manhattan Island led to the crowding of the ground, he was not previously aware that the resulting buildings had been accepted as the type of American architecture. He admired those buildings, and he agreed that they were the natural outcome of the conditions, but it was impossible not to feel some dissatisfaction with the idea that they were buildings of which the whole exterior more or less imitated a construction which was not the real construction; and if that system of building tall steel buildings was to be made architectural there should be some effort to design the exterior, so that it actually conveyed to the mind that it was only steel; that it should avoid giving the impression that it was an imitation of a stone structure. Was it possible to carry out those high buildings in ferro-concrete, instead of with a stone skin, so that the exterior should represent the actual construction? Pictures had not been shown of very high buildings in concrete steel. To Europeans, who had been accustomed to regard architecture as buildings in stone and brick, that idea of the outer skin went against one's prejudices. He had the feeling that he would like to see the exterior aspect of a building represent its actual construction. His own feeling had been, in regard to many of the buildings illustrated, that the base, from the architectural standpoint, was not strong enough. Probably that was also a question of light; but if larger piers were put in the basement it would have a better effect. What had been said about the influence of tradition in American architecture was very interesting. He thought American architects had given themselves over too much to the cult of the Beaux Arts, and if they would try to evolve a style of their own it would be well. If one adopted the general feeling of classic forms, one might put something into them which was in harmony with them, and yet not necessarily copying.

Mr. John Slater, F.R.I.B.A., desired to endorse what had been said as to the interest of the paper. Three years ago he went to New York, and he felt what Mr. Andrews had said as to the imposing effect of the high buildings when seen from the river. The fact that the gaps between them were now being filled up was a very good feature, because to stand in one of the narrow streets and look over a low building at the side of one of the lofty structures was one of the most

depressing things which could be imagined. With regard to some of the pictures shown, especially of the purely utilitarian structures, he thought a sufficient attempt had not been made to emphasise the corners. One building was rather alarming to look at because of the thinness of its corner. Notwithstanding the necessities of lighting, if those structures were to be put up it might be possible to give a little more apparent strength to the corners. It was very interesting to hear about the stimulus towards the artistic appreciation proceeding from the artist to the patron. He feared that the patron in America gave more fertile grounds for those stimuli than in this country; but there could be no doubt, from what was known about the spread of architectural education in the States, and the way in which the various colleges and municipalities were providing for the proper education of art students, that the intelligent appreciation of architecture was greater in the States than here, and that was a matter upon which the Americans were to be congratulated, while we must deplore the lack of it in ourselves.

Mr. ANDREWS, in reply, expressed his warm appreciation of the way in which his paper had been received. He hoped that when next his hearers saw anything which pertained to the work of the United States, the paper would help them to understand what it was that had caused it to be with all its faults—and he hoped some virtues—what it was, and the directions in which the country was tending. He would not wish those high buildings put in any part of Europe, because they had nothing to do with their conditions or mode of life, and they would be an entire misfit. They belonged to America, and were not freaks. The freakishness would be eliminated from them by educating the landlord and the public, when the former allowed the corners to be made wider and to occupy more space.

HOME INDUSTRIES.

State Insurance.—The further discussion of the National Insurance Bill has proceeded upon lines favourable in the main to the scheme, whilst disclosing many matters of important detail that cannot be reconciled one with the other. Part II. of the Bill, which deals with Unemployment, is, perhaps, the more doubtful section of the present proposals. In introducing the Bill, the Chancellor of the Exchequer said that many efforts had been made on the Continent, "mostly failures, because they are all on the voluntary principle." This is a mistake. By a happy coincidence Mr. J. G. Gibbon has just published "Unemployment Insurance," a study of schemes of assisted insurance. Mr. Gibbon has carried on his investigations in connection with the sociological work of the University of London. A draft of the book was completed about the middle of last year, but Mr. Gibbon decided to await the receipt of the new material which would be available in connection with the International Conference on Unemployment which was to be held in Paris in September. The reports prepared for the Paris Conference provide a rich store of material, from which Mr. Gibbon has drawn freely. In a brief preface, Professor L. T. Hobhouse says that "the most important result which emerges from Mr. Gibbon's investigation is the contrast between the success of the Ghent system of insurance and the difficulties and failures that have beset other experiments. One of the great merits of this system is that it dispenses with compulsion, and this is of the more interest for us because under British conditions compulsion would probably encounter peculiar difficulties, and if it can be dispensed with the whole problem will be sensibly lightened." Compulsory insurance against unemployment has been actually tried at only one place, St. Gall, Switzerland. Full particulars of its operation will be found in a "Report to the Board of Trade on Agencies and Methods for dealing with the Unemployed in certain Foreign Countries," by D. F. Schloss, 1904, p. 143, and in "Insurance against Unemployment," by D. F. Schloss, 1909, p. 8. Mr. Gibbon tells us that a law was passed in 1894, in the Canton of St. Gall, which authorised any Commune to set up a scheme of compulsory insurance against unemployment. Insurance could be made compulsory for all workmen earning not more than 4s. a day, unless they were equally insured otherwise, and could be made optional for persons earning more. The local authority could also make insurance compulsory for women. The scheme was in force in the town of St. Gall for two years. It was then abandoned, mainly at the instance of the better class of workmen. It was badly conceived and as badly executed. There was no adequate check of unemployment. Persons drew benefit who had no legal right to it. The scheme was administered by the Poor Law Department, and therefore became connected with the poor law in the minds of the people. The better class of workmen, from the beginning suspicious of the scheme, became the more bitterly opposed to it when they saw the abuses which arose. Commenting upon its failure, Mr. Gibbon remarks that it is unfortunate that it should have been necessary to discard the one scheme of compulsory insurance against unemployment which has actually been put into practice, largely because of palpable defects of administration, without a fair test of the principles on which it was based. Direct experience, so far as it goes, is against compulsion. Only one such scheme has ever been tried, and that signally failed. Proposals to establish compulsory schemes have been considered at several places, but not adopted. At Basle, the electors in 1899 rejected a compulsory scheme by referendum after it had been passed by the legislative body.

Unemployment Benefit.—The extent to which unemployment benefit actually exists is not generally appreciated. In the report of the Board of Trade on the work of the trade unions of the

United Kingdom during the years 1905 to 1907 it is estimated that in all some £514,000 was expended during 1906 by trade unions in the United Kingdom in unemployment benefit. This sum was disbursed by some 750 trade unions. Particulars published in *The Labour Gazette* show that over £1,000,000 was expended by the 200 principal trade unions in unemployment benefits in 1908, and over £940,000 in 1909. During the ten years 1900-9, unions included in the principal hundred provided in all over £5,500,000 in benefits of this kind. In some industries, mining especially, slackness is met by working short time, and therefore comparatively little unemployment benefit is paid. The benefit paid in the several trade unions differs very considerably. In many of the more skilled trades the rates of benefit are not very high, but the period for which benefit may be received is long. Thus a member of the Amalgamated Society of Engineers of over ten years' standing can receive 10*s*. a week for fourteen weeks of unemployment, 7*s*. for the next thirty weeks, and 6*s*. a week for the remaining period of unemployment. The average annual expenditure per head of membership in eight of the principal unions for the years 1898 to 1907 was: London Compositors 29*s*., Ironfounders (England) 24*s*., Boilermakers and Shipbuilders 19*s*., Amalgamated Carpenters and Joiners 16*s*., Amalgamated Engineers 14*s*., Cotton Spinners 12*s*., Typographical Association 11*s*., Durham Miners 3*s*. These figures give the actual average charge on members in respect of unemployment pay. In two instances the amounts provided were over 5*d*. a week per member, in three instances over 3*d*. a week. These payments are made to provide against one of the several contingencies of a workman's life. In some industries the practice is to work short time when trade is slack, so that little is paid in unemployment benefit, even when the total unemployment is high. The thirteenth abstract of labour statistics shows that the average unemployment for the ten years 1899 to 1908 for all the trade unions making returns was 4·3 per cent. In the shipbuilding trades it was 9·5 per cent., in the building trades (carpentering and plumbing) 5·9 per cent., in the furnishing trades 5·8 per cent., in the engineering trades 4·8 per cent., in the printing trades 4·6 per cent. In 1899 the percentage of unemployment for all trades was 2 per cent., which would make necessary a contribution of about 2½*d*. a week to provide a benefit of 10*s*. a week for unemployed persons, whereas in 1908 the percentage of unemployment was 7·8 per cent., which would have made necessary a contribution of about 9½*d*. Much has been done by the trade unions to assist the unemployed, but much remains to be done. It has been estimated that "probably 6,000,000 or 7,000,000 men over twenty years of age belonging to the classes from which trade unionists are drawn have not yet joined a trade organisation." This from the report of the Poor Law Commission, Part VI., chap. 4, para. 592. Only 1,500,000 workers are insured, and even of these many are but meagrely insured.

Curtailment of Production of Cotton.—The suggestion is made in Manchester of a general arrangement to close the mills one day per week until margins improve, and it would seem desirable that cotton spinners should agree to put a check upon yarn production, seeing that the quantity of raw cotton in this country and on the way here may not be sufficient to see them through until the present crop arrives. What is wanted in the cotton trade is the organised curtailment of production when trade is unprofitable. Too much yarn is being produced, and unreal reports of conditions of trade are used to support speculators in their actions. Production was reduced by the numerous cotton mills spinning coarse and medium counts, which use the major portion of the cotton crop. What good reason is there for the continued working of mills at a loss? The gainers are the cotton brokers, manufacturers, and yarn agents. Why should the spinners bear the drain of maintaining them? The decisions of the International Conference should be acted upon.

Hire-Purchase of Lace Machinery.—The Parliamentary Committee of the Nottingham Chamber of Commerce are investigating the question of hire-purchase of machinery. In Nottingham there are numbers of factories with several tenants and a common water-supply, the building sometimes being owned by firms or individuals who are not lace manufacturers at all. For instance, the Clyde Works are owned by the Clyde Works Company, Limited, and there are twenty-six firms housed in the premises engaged in net, curtain, and other trades. According to Mr. F. B. Stabel—a well-known Nottingham man in the trade—under existing conditions a man can purchase two lace machines for £1,000 each, paying £50 down on each machine, with the result that "a lot of men of straw embark in the lace trade who have no business in it." If financial difficulties arise the machinery is seized by those who supplied it, and there is nothing wherewith to meet other indebtedness. Of late there have been several cases of the kind, not only the machine being claimed but also the yarn "in process."

The Aluminium Convention.—This Convention was formed last February, and it has run its course. The agreement was between the Neuhausen Company, the French makers, and the British Aluminium Company, but it made no direct attempt to regulate production, and no penalties appear to have been attached to the breaking of the terms, the most important of which related to the maintenance of a standard price (136 marks per 100 kilos). The arrangement was for three months only, and the French works having notified their unwillingness to renew the contract the Convention expires. It was thought when it was brought about that it might serve as the basis on which to found a more efficient organisation, but it has not worked well.

The Oil Trade Rivalry.—The rivalry between the competing oil companies shows no signs of

abatement. Of late years, and outside the Scotch Mineral Oil Companies, the three great distributing concerns have been the Anglo-American Oil Company, which represents the Standard Oil Company; the British Petroleum Company, representing the Royal Dutch-Shell Transport interests; and the Home-Light Oil Company, originally known as the Caucasian Petroleum Export Company. The Home-Light Company's British interests have now practically passed to the British Petroleum Company, and between this and the Standard Oil Company the conflict is fierce. Throughout the past burning-oil season retailers in the most distant districts have been able to buy oil at less than 3*d.* per gallon net. And the competition is keen in motor-spirit as well as in burning-oil.

GENERAL NOTES.

LECTURES IN ADVANCED ENGINEERING. — A course of five lectures on "The Application of Hyperbolic Functions to Electrical Engineering Problems" will be given at the Institution of Electrical Engineers, Victoria-embankment, by Dr. A. E. Kennelly, at 5.30 p.m., on May 29th, 30th, 31st, and June 1st and 2nd, 1911. The lectures are addressed to advanced students of the University of London, and others interested in the subject dealt with. Admission will be by ticket obtainable on application to the Secretary of the Institution.

PRODUCTION OF ELECTRICITY FOR MOTIVE POWER IN ITALY.—The use of electricity for motive power for industrial purposes has increased to an enormous extent during the last ten years in Italy. This is especially noticeable in the production of electric energy by water-power as compared with that furnished by steam, gas, or by other heat motors. In 1900 the total energy produced amounted to 82,000 horse-power, whilst two years later it had nearly doubled, being 157,000 horse-power, of which 92,000 horse-power was supplied from power-stations driven by hydraulic power, and 65,000 horse-power by steam or other heat engines. The following statistics show the rapid increase in the amount of electric power furnished yearly up to December 31st, 1909:—

	Horse-power by hydraulic motors.	Horse-power by steam, etc.	Total horse-power.
1903	101,000	80,000	181,000
1904	139,000	100,000	239,000
1905	190,500	125,000	315,500
1906	245,000	155,000	400,000
1907	383,000	195,000	578,000
1908	409,000	225,000	634,000
1909	510,000	240,000	750,000

It is estimated, in consequence of the completion of many important power-stations both in the north and south of Italy, that the total production of motive power did not fall short of one million horse-power. The following returns of the number and horse-power of engines employed in the mining, metallurgical, and chemical industries in 1909, give some idea of the importance played by electricity in this country:—

	No.	Horse-power.
Hydraulic motors	945	67,876
Electric motors	1,457	44,301
Steam engines	1,245	94,098
Gas engines	465	31,493
Oil, etc., engines	20	599
	4,132	238,367

REGULATIONS FOR WIDTH OF WHEEL-TYRES IN ITALY.—The following regulations respecting the width of the tyres of wheels for vehicles, in relation to their weight, in use on public roads and highways in Italy have been issued lately:

For Two-wheeled Vehicles.

Gross Weight, Vehicle and Load. French. Quintals.	English. Tons.	cwts.	lbs.	Width of Tyre. French. Centimetres.	English. Inches.
6	—	11	91	4	1·57
10	—	19	77	6	2·36
20	1	19	42	8	3·14
50	4	18	49	12	4·72
For Four-wheeled Vehicles.					
10	—	19	77	4	1 57
15	1	9	59	6	2·36
30	2	19	7	8	3·14

Weights exceeding the above and up to 70 quintals (6 tons 17 cwts. 91 lbs.) may be carried on wheels having tyres of india-rubber or other elastic material. Special permission from the competent authority must be first obtained should the loads exceed 70 quintals in weight.

THE CORROSION OF METALS.—A recent Australian invention to overcome troubles of corrosion and pitting in metals, especially boilers, due to electric chemical action of ingredients in water with which they are brought in contact, appears to have met with success in Sydney, according to the American Consul there, and the owners of this invention have just made arrangements for its thorough test by the Canadian Pacific Railway in some of its engines in districts where there has been much trouble from boiler corrosion. The plan of the invention is to introduce, by dynamos, weak electrical currents on to the metals intended to be protected, thus neutralising the galvanic action of the corrosive substances contained in the water. The process can be worked from any electrical installation already in use, the amount of electricity required being extremely small and such as can be easily regulated. The process is intended to be specially used, not only for the protection of boilers, but also for protecting condensers, digesters, feed-water heaters, tanks, tail shafts, stern frames of ships, etc. The invention is expected to make an immense saving by eliminating the necessity

for using zinc in various forms, boiler fluids, etc., to combat corrosive tendencies, and also in dispensing with retubings and other repairs. This new electrical process was recently tested by the Professor of Physics at the Melbourne University on metals immersed singly and in connected pairs in sea water, both hot and cold, and in dilute acids, who reported that all hurtful galvanic action was suspended by a small expenditure of electrical power. Successful trials have subsequently been reported, says the Consul, by engineers of the Melbourne Steamship Company, the Sydney Municipal Powerhouse, and the Union Steamship Company of New Zealand.

THE PALM-FIBRE OR "COGOLLO" INDUSTRY IN VENEZUELA.—The palm-fibre, or, as it is locally known, the "cogollo" industry, has for many years been of great economic importance in Venezuela, particularly in the Maracaibo district. There are districts where the majority of the families depend upon this product for a livelihood. The fibre is obtained from a small palm called "palma de cogollo." Only the young shoot or centre leaves are gathered. The first cutting can be made when the plant is one year old, and thereafter from two to three times a year. After the leaves are gathered they are placed in large earthenware jars. These jars are then filled with water, to which has been added the juice of three or four lemons, and the fibre is allowed to soak for six to ten days to remove all vegetable saps and resins. After this the leaves are spread in the sun for several days until they are bleached to a cream-white. They are then made into bundles weighing about two pounds each, and are ready for market. The leaves are soft and pliable, and are split into narrow ribbons, which, when moistened, may be rolled into a string-like form, and then woven into hats. The hats made from the Venezuelan cogollo are practically the same as the so-called "Panama" hats, but are seldom so fine-grained or well made as the Ecuadorian or Colombian hats.

TECHNICAL EDUCATION IN BRAZIL.—The Brazilian Government have recently authorised a system of schools and stations to teach agriculture in the several States, in harmony with the plan for apprenticeship trade-schools. At the head is to be a higher school of agriculture and veterinary surgery, with seat at Rio de Janeiro. The school will give education fitting students for places as experts in the general extension of agricultural training. With the co-operation of the State Government, agricultural schools, experimental stations, model farms and stock ranches will be established as soon as the general working out of the plans justifies such work. Elementary instruction in rural industries will be encouraged in schools for elementary education already established. By demonstrations at experimental stations and elsewhere it is intended to instruct farmers in the use of modern implements and methods necessary to success in farming.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 29...Indian Guild of Science and Technology, King's College, Strand, W.C., 8.15 p.m. Dr. Bidhau Chandra Roy, "The Public Health Problems in India."

Surveyors, 12, Great George-street, S.W., 5 p.m. Annual Meeting.

Geographical, Burlington-gardens, W., 8.30 p.m. Professor W. L. Grant, "The Geographical Conditions affecting the Development of Canada."

North-East Coast Institute of Engineers and Shipbuilders, Bolbec Hall, Westgate-road, Newcastle-upon-Tyne, 7.30 p.m. 1. Discussion on Mr. P. B. Newell's paper, "Some Problems relating to the Use of the Internal Combustion Engine for Marine Propulsion." 2. Discussion on Mr. Joseph Chilton's paper, "Some Notes on the Speed and Power of Machine Tools."

TUESDAY, MAY 30...Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. W. Watts, "The Ancient Volcano of Charnwood Forest, Leicestershire." (Lecture I.)

WEDNESDAY, MAY 31...Public Analysts, at the Chemical Society's Rooms, Burlington House, Piccadilly, W., 8 p.m. 1. Mr. H. Droop Richmond, "The Composition of Milk." 2. Messrs. Cecil H. Cribb and P. A. Ellis Richards, "Notes on the Analysis of Margarine." 3. Messrs. Cecil Revis and E. Richards Bolton, "Observations on some Methods of Estimating Cocoanut Oil and Butter in Butter and Margarine." 4. Messrs. T. Cockburn and J. W. Black, "The Estimation of Quinine as the Acid Citrate, in certain Organic Liquids." 5. Mr. R. W. Clarke, "The Determination of the Amount of Dissolved Oxygen absorbed by Sewage Effluents containing Nitrite, and of the Amount of Nitrite in Sewage Effluents of Water." 6. Messrs. Cecil Revis and E. Richards Bolton, "Further Analyses of Ghee."

Concrete Institute, 296, Vauxhall-bridge-road, S.W., 5.45 p.m. Mr. R. W. Vawdrey, "Reinforced-Concrete." (Lecture VI.)

Mining and Metallurgy, at the Institution of Mechanical Engineers, Storey's Gate, S.W., 8 p.m. 1. Mr. C. O. Schmitt, "Future Economies in Rand Reduction Plants." 2. Mr. Arthur C. Hoare, "The Roasting of Complex Ores in Gold Assaying." 3. Mr. G. M. Austin, "A Prospector's Method of Gold Assay."

THURSDAY, JUNE 1...Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. R. M. Caven and H. J. S. Sand, "The Dissociation Pressures of the Alkali Bicarbonates. Part I. Sodium Bicarbonate." 2. Messrs. J. J. Dobbie and A. Lauder, "The Absorption Spectra of Cinchonine, Quinine and their Isomers." 3. Messrs. C. R. Crymble, A. W. Stewart, R. Wright and Miss F. W. Rea, "The Influence of Conjugated Linkings upon General Absorptive Power. Part II. Some Open-Chain and Cyclic Compounds." 4. Mr. F. Tutin, "The Constituents of the Bulb of Buphane Disticha." 5. Mr. J. Weir, "New Derivatives of Aminolauronic Acid." 6. Messrs. M. O. Forster and S. H. Newman, "The Triazo Group. Part XVIII. β-triazoethylamine." 7. Messrs. C. F. Cross and E. J. Bevan, "The Interaction of Formic Acid and Cellulose." 8. Mr. A. McKenzie, "Configuration of the Stereoisomeric Dibromosuccinic Acids. Preliminary Note."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. T. Thorne Baker, "Changes Effected by Light."

FRIDAY, JUNE 2...Royal Institution, Albemarle-street W., 9 p.m. Commendatore G. Marconi, "Radio-telegraphy."

SATURDAY, JUNE 3...Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. L. Courtney, "Types of Greek Women." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,054. VOL. LIX.

FRIDAY, JUNE 2, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

CONVERSAZIONE.

The Society's annual conversazione took place at the Natural History Museum, Cromwell-road, S.W. (by permission of the Trustees of the British Museum), on Tuesday evening, May 30th. The Reception was held in the Central Hall of the Museum by Sir John Cameron Lamb, C.B., C.M.G., Chairman, and the following members of the Council:—Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., Mr. Alan Summerly Cole, C.B., Mr. William Henry Davison, Mr. Robert Kaye Gray, Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., The Hon. Richard Clere Parsons, Sir Boverton Redwood, D.Sc., F.R.S.E., Mr. Carmichael Thomas, Professor John Millar Thomson, LL.D., F.R.S., Sir Aston Webb, C.V.O., C.B., R.A., F.R.I.B.A., and Colonel Sir John Smith Young, C.V.O.

The following portions of the Museum were open:—The Central Hall, containing cases of specimens illustrating mimicry; adaptation of colour to surrounding conditions; protective resemblance, etc.; the North Hall, containing the collection of domesticated animals; the Bird Gallery, containing groups of British birds and nests, etc.; the Fish Gallery, the Shell Gallery, and the East and West Corridors on the first floor.

A selection of music was performed by the band of H.M. Royal Regiment of Artillery, under the direction of Mr. E. C. Streeton, Bandmaster, R.A.

A vocal and instrumental concert was arranged in the Shell Gallery, and a miscellaneous entertainment was given in the Fish Gallery, under the direction of Mr. Patrick Kirwan.

Messrs. Steinway and Sons kindly lent two pianos for use at the concert, etc.

The number of visitors attending the Conversazione was 1,292.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A Meeting of the Indian Section was held on Thursday, May 25th, 1911, the Right Hon. the Earl of Minto, K.G., G.C.M.G., G.C.S.I., G.C.I.E., in the chair.

The Chairman said he had great pleasure in introducing the reader of the paper, Mr. Merk. Mr. Merk had had a very distinguished career—so distinguished that his lordship could not trust himself to recapitulate offhand the various appointments he had held. He practically began his political duty in the Afghan Campaign of 1879-1881, where he did excellent service, which was recognised by his appointment to the Punjab Government Secretariat. Subsequently, in 1884, he joined the Demarcation Commission of the Anglo-Russian Frontier as Attaché, and was with the Commission the whole time it was on duty, and for his services with it received, in 1887, the C.S.I. He then became Deputy-Commissioner of Peshawar, and all who knew the frontier realised that this was a most important post; and when we took over the Kurram Valley, in 1892, he was appointed its first administrator. His lordship was there quite recently with Mr. Merk, who had revisited his old haunts; and he thought he could honestly say that the prosperity of Kurram was largely due to Mr. Merk's administration. After that, Mr. Merk was in supreme political charge of the Mahsud Expedition in 1902; they had been told not to call it an expedition, but a blockade. After that, he returned to the Punjab, and latterly had been acting as Chief Commissioner of the North-West Frontier Province. Mr. Merk was a most accomplished linguist in many languages, and naturally possessed a very thorough knowledge of Pashtu. His lordship was glad to see him so vigorous and in good health, and he hoped he had many years before him yet in which he would be able to render still further service to the country, which already owed him so much.

The paper read was—

THE NORTH-WEST FRONTIER PROVINCE OF INDIA.

By W. R. H. Merk, C.S.I., LL.D.

The North-West Frontier Province, on which I have the honour to read you a paper to-day, is the youngest, if we except Eastern Bengal, of the Provinces into which British India is divided, having been constituted in 1901. In respect of population, and of the extent of territory that is fully administered according to the British law, it is also the smallest; but I think one may safely claim on its behalf that no other Province excels it in interest.

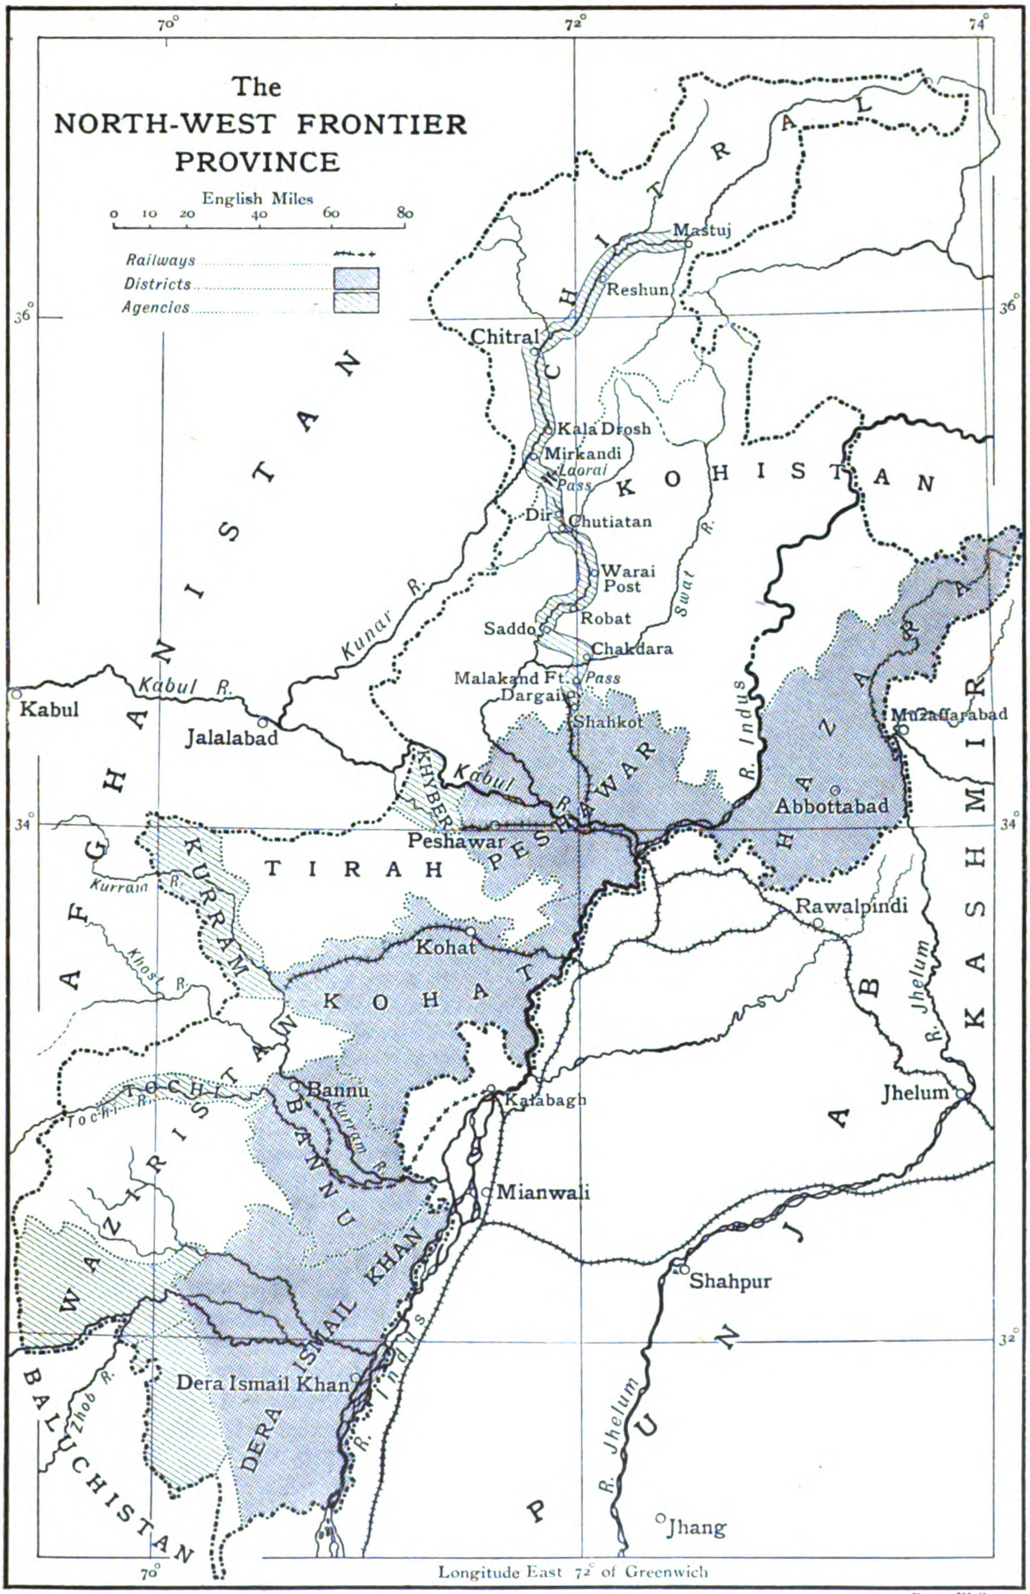
The gates of India towards Central Asia must ever have an attraction of their own. We are here on classic, historic ground. In dim, pre-documentary times, there poured through the gaps of its western ramparts that race of highly-gifted Asian shepherds and cultivators who gradually rescued India from the hold of the dark Dravidians, and founded an ancient and enduring civilisation, the highly-developed religious and philosophic creeds of which have from time to time exercised a profound influence upon the Western world. The passes beyond the Indus have given admittance to such orderly conquerors as Alexander the Great and Baber, the Great Mogul, whose aims were to construct rather than to destroy. The furious onslaughts of Mahmud of Ghazni, that shattered the stately edifice of civilisation in Northern India reared during many centuries of Buddhist and Brahmanic care, were first delivered in this neighbourhood. The blood-thirsty hordes of Chinghiz Khan, Tamerlane, and Nadir Shah, which wrought such hideous ruin in India, passed through this Province; as did the last invasion of Northern India, when Ahmed Shah and his Afghans came down, only 150 years ago, to crush for ever the hopes of the Mahrattas and to pave the way for a new development: the advance of another orderly conquest and of a high civilisation from the sea to the hills, from the east and south towards the west thereby reversing the processes of past ages.

To students of history, this part of India possesses a peculiar fascination. It is not without great attractions for those who are called to take an active and practical part in life, whether as soldiers or as civilians. The extraordinary diversity of scenery and terrain within the limits of the Province; the wild and martial character of the bulk of its inhabitants; the question of eminent importance which is presented in the problem of how to tame and civilise the Albania that forms its greater portion; the desperate struggles that have occurred in its hills; the achievements of Nicholson, Edwardes, Reynell Taylor, and Cavagnari, Lumsden and Wigram Battye of the Guides, Mackeson and Abbott and Neville Chamberlain—all combine to create a glamour which it would be difficult to match elsewhere in India, and which fires the imagination of the frontier man, of whatever race he be. It is well, in a way, that this should be so, for life on the frontier is by no means always a bed of roses.

As the Province has come into being only recently, it may be convenient to give you a few statistical facts in connection with it, which will afford a general idea of its circumstances. The first thing that strikes one is the length of the charge as compared with its breadth; the second is that, from an administrative point of view, it comprises two totally distinct and dissimilar forms of jurisdiction, to which there is no parallel elsewhere in India. Taken together, they considerably enhance the gravity of the task that is laid upon the administration; the first difficulty can be overcome by improving to the utmost the means of rapid communication, and much has already been accomplished in that direction; the second difficulty will find its solution in the course of time; what that solution will be no man as yet can say, but it is at any rate permissible to suggest that it should be conducted on peaceable and conciliatory lines, if that is in any way honourably possible, and provided that the force of circumstances is not too strong for us owing to unforeseen exigencies or to the wilful opposition, one might almost term it the insanity, of the people concerned themselves.

The North-West Frontier Province lies between the 31st and 36th degrees of latitude, and the 69th and 74th degrees of longitude; or, to be less technical, it stretches for over 400 miles as the crow flies, from the Pamir Steppes, the Roof of the World, to a point south of the latitude of Lahore, the capital of the Punjab.

I have alluded to the diversity of topographical conditions in a Province, the highest point of which lies in the eternal snows at an altitude of 25,000 feet above the sea and the lowest portion of which, at Dera Ismail Khan, descends to 400 feet from sea level. Every kind of climate, vegetation, and physical aspect can be found here. In the north lies the barrier of the



Districts are indicated by dark shading, Agencies by light shading.

glistening peaks and enormous glaciers of the Chitral ranges, their sides scored by narrow glens and tremendous gorges; further south we come to the well-wooded hills of Bajour, Dir, Swat, Buner, the Black Mountain, and Hazara, enclosing fertile, smiling valleys, and in Hazara affording an ample selection of sites for sanatoria; next comes a remarkable physical division of the terrain, which has had an important political bearing, in that the plain has always been more or less under a settled government, whereas from time immemorial the hills have been independent. From where the Indus emerges out of the northern group of mountains to the point where it leaves the Province a plain flanks its proper right bank. In the Peshawar district this plain widens into a great bay in the shape of a horseshoe, encircled by hills, which was evidently the basin of a former lake. After the mighty river has forced its way through a relatively low transverse range, the plain reappears in the districts of Bannu and Dera Ismail Khan, and so continues to the sea. It slopes up to the western hills at a varying breadth of forty to sixty miles, and is at first cut up by deep ravines and rocky hills (the raiders' opportunity), till these gradually melt into a flat and dreary expanse of waste and desert, with which many of you must have been painfully familiar. To the west of this plain, from Peshawar to the southern extremity of the Province, lie masses of wild and rugged hills, often rising into ranges of great height, such as the Sufed Koh and the magnificent Takht-i-Suleman, a country of precipices, cliffs, and inaccessible glens. Rarely do these widen into fertile and irrigated dales. Speaking of the tract south of Kurram and Kohat, Baber, who knew a good deal about it, records:— "There are, perhaps, scarcely in the whole world such dismal-looking hill countries as these; they have all a uniformity of aspect, being very low, having little grass, bad water, and not a tree. It is an ugly and worthless country." I do not think many will contradict him. But there are other sides to the picture. Few who have seen the valleys of Kurram or Peshawar in the spring will forget the exquisite beauty of the landscape; and the sight of a thunderstorm sweeping across the plains of Bannu is a momentary compensation for existence on that lonely rock, Sheikhbuddin. Even the jagged peaks and cliffs of Waziristan and the wide deserts at their base are not without a sterile grandeur. I cannot resist quoting to you a piece of descriptive writing (by Colonel James, who fifty years ago was Commissioner of Peshawar) which portrays a typical bit of frontier scenery, and is as true as it is fine:—

"Those who have travelled much among the Afghans, and visited them in their sequestered valleys, retain a pleasing impression of the general characteristics of their homes. Emerging from wild and craggy defiles, with a solitary tower here and there perched up on the overhanging rocks, the stranger comes suddenly upon the village site; springs of refreshing clearness pass from rocky cisterns to the brook which had repeatedly crossed his path in the defile, and which is here fringed with rows of weeping willows and edged with brightest sward. The village is half hid from view with overhanging mulberry and poplar trees, the surrounding fields enamelled with a profusion of wild flowers and fragrant with aromatic herbs. At some distance is seen a wood of thorn and tamarisk, in which are the graves of the village forefathers; an enclosing wall of stone, and the votive shreds which are suspended from the overhanging tree, pointing out the 'ziarat' of some saintly ancient, which children pass with awe and old men with reverence. The dream of peace and comfort, which the contemplation suggests, is, however, rudely dispelled by the armed ploughman, who follows his cattle with a matchlock slung at his back; by the watch-tower occupied by a party of men to guard the growing crops, and by the heaps of stones visible in all directions, each of which marks the spot of some deed of blood. We cease, indeed, to be surprised at the love of home, which is so marked a feature of the Afghan character; for, reared in a little world of his own, the association of his childhood must make a more than ordinary impression on his mind, but we might expect that such scenes would engender other feelings than those which lurk in the breast of the robber and assassin. . . . Their hills are full of sacred spots, and upon the tops of mountains, hid in clefts of rocks, placed on the roadside, where a spring issues from the earth or where a clump of trees affords unwonted shade, the rude grave is to be found of some holy man deceased, adorned with white stones and pebbles, where the sick resort to be healed, and those who are bound on any enterprise, to pray, and where at times may be seen the solitary lamp, kindled in gratitude by one who has slain his enemy or gathered unusual spoil."

The upper half of the Province is drained by the rivers of the Indus, Swat, Panjkora, and Kunar; the three latter fall into the Cabul river, which itself swells the volume of the Indus at the old Moghul fort of Attock. Their junction during floods is the scene of a wild confusion of waters, about two miles in width, before they are compressed into the gorge by which the Indus bursts through a range of low hills, past Khushalgarh, to spread itself over the country beyond. There, at Dera Ismail Khan, during the season of the rains and melting of

the snows, it may attain a width of over ten miles. The southern half of the Province can boast of few perennial streams. The principal are the Kohat, Kurram, and Tochi rivers, and the Gumal—as a rule, modest affluents of the Indus but apt, like the generally dry hill watercourses of this region, to come down in terrific spates after unusual rain. As with the rivers, so with the rainfall; it is heaviest in the north and steadily diminishes towards the south. In Chitral it is 17 ins. in the year; lower down we come within the area affected by the monsoon, and in the Hazara district it is 45 inches, but at Peshawar 12 inches, the same at Bannu, and only 8 inches in Dera Ismail Khan. Excluding the Hazara district and the northern hills, the cultivation which is dependent upon the rainfall alone is most precarious, and water supplied by irrigation is the life of the people, a subject to which I shall revert presently.

In this land of rocks and stones one would expect to meet with valuable minerals, but except some orpiment in Chitral, an inferior marble in the Peshawar district, the huge deposit of grey rock-salt in Kohat, where it occurs in the form of veritable hills, and some good coal near the Indus in the Bannu district, there are none. It is possible, however, that paying quantities of oil may be found in the Sherani hills, at the extreme southern border of the Province; if so, that will revolutionise the economic conditions of that arid region and provide much employment with the means of livelihood for the hungry and idle hillmen of the neighbourhood.

The greatest breadth of the Province is 280 miles, but that is an extreme case; on an average the territory in question is from 100 to 150 miles wide. The contrast with other compact Indian Provinces is obvious. The total area comprised within its limits is, in round numbers, about 38,000 square miles, or somewhat more than three-fifths of the size of England without Wales. But only 13,000 square miles (one-third of this tract) are under full British law and administration—that is to say, are what is commonly understood by the expression "British territory." By far the greater part, or 25,000 square miles, is occupied by tribes who are under British political control, but who maintain their internal or municipal independence. The British territory part of the Province is divided into the five districts of Hazara, Peshawar, Kohat, Bannu and Dera Ismail Khan. These districts stand almost entirely on the same footing as districts lying Cis-Indus in respect of laws and justice, revenue system, education, excise, police, and the thousand-and-one items that go to make up the sum total of our administration in India. Whether at the beginning it would not have been better to have introduced a more simple system, more adjusted to the special wants and circumstances of a rough frontier people and country, in a then out-of-the-way corner of India, it is somewhat late to consider now. It is not easy to set back the hands of a clock that has been running for sixty years. Vested interests, rights and obligations have arisen and become established that must be respected, and a sudden or general reversal of the course of administrative evolution might lead to greater evils than those that it would be sought to rectify. But it is quite possible to retard excessive elaboration; and doubtless in some departments of the administration, such as the revenue system, it is feasible to simplify. I may note here that steps are now being taken in that direction. How this state of things came about it is not difficult to understand; on the annexation of the Punjab the present frontier districts were included in that Province; from which, as I have said, they were separated only nine years ago. Being in the Punjab the districts were treated on the same administrative lines as the Cis-Indus portion of that Province in which, however, during the early years that followed the Sikh wars, the system was anything but intricate and elaborate; it was rough and ready, and the personal element in the governing of the country predominated. Across the Indus, as can be imagined, this patriarchal state of things was accentuated—"it was a far cry to Lochawe"—and the local hakim or ruler represented all authority in the minds of the people. Even long after the administrative system had crystallised in the Punjab proper, it remained more or less fluid across the Indus, and when I first went to the frontier, thirty-three years ago, it was still considered to be far behind the rest of the Punjab. Gradually that charm that centralisation and bureaucratic methods possess for the human, and especially the Oriental, mind—there is no such bureaucrat and red-tape clerk as the Oriental when he gets his chance, and the preponderating bulk of our staff is Indian—almost insensibly began to assert itself, and the frontier districts came in for their share of the administrative elaboration that has taken its rise of late. Even so, in matters of justice, it was found that concessions were necessary to the special

conditions and difficulties of the frontier, and forty years ago a tentative step was taken by the introduction on a very circumscribed scale of the "jirga" system. Fifteen years ago it was considerably amplified, and, with further extensions adopted in 1901, that system is in full force. Briefly the "jirga" system is this: in civil claims over questions that fall within the sphere of tribal custom, and in all criminal cases before they have been finally decided by a regular court of justice, the chief civil authority in a district can, in his discretion, refer the matter for the verdict of men, viz., the "jirga," selected by him and conversant with the subject of dispute or with the circumstances of the criminal charge—much as the British jury, in its origin, consisted of men who were acquainted with the facts and being upright, could assist the King's Courts by stating what they knew to be the truth; not by way of evidence in the capacity of witnesses, but as judges by way of finding. It will be realised that the success of such a system rests mainly with the people themselves, it lies in their hands to make it by honest verdicts or to mar it by perverse, factious, and corrupt proceedings. The regulation or law that enacts the "jirga" system contains safeguards against its abuse; also various powers are given by it for the preservation of order and the support of authority in a turbulent tract. With the details of these I will not trouble you. It is sufficient to note that the special conditions of a frontier country have so far been recognised in their judicial aspect. And, as already mentioned, the simplification of the revenue system is in course of being carried out.

In these districts the King's writ runs as freely as all over India. They have, therefore, been marked by a dark shading on the map. Their western boundary, which is known as the administrative border, and which I would call "the inner provincial border," is a sinuous line, which extends for some 600 miles. All along this great distance it is exposed, potentially, at every point to the inroads for plunder—the forays—of the warlike tribes that live beyond it; but, as is natural, there may be, and generally is, a profound peace on most of it even when there are lively times at one particular point. I would ask you always to remember when you hear the border is disturbed, that raiding at one spot does not necessarily mean widespread unrest or a conflagration, any more than the battle of Sidney Street in London implied a general action going on down Prince's Street, Edinburgh. On the other side of the inner border there dwell the municipally independent tribes who are under the political control of the Chief Commissioner, which he exercises with the aid of the officers in charge of the five Political Agencies—viz., Swat, Dir, and Chitral; the Khyber; Kurram; Northern and Southern Waziristan. These Agencies, which are marked by a light shading, can be described as the five fingers or tentacles of civilised order, stretching into a mass of barbarism and savagery. In between the Agencies, the space left white—which, however, is by no means emblematical of innocence—is that which is occupied by the independent tribes as far as the "Durand line" or "the outer provincial border." This line separates the respective British and Afghan spheres of political influence and control, and was accepted by the Governments concerned in 1893. It has mostly been demarcated; the greater part of the still undelimitated section lies along the watershed of high mountain ranges. The length of this outer border cannot be less than 800 miles. Except in Kurram, and in lesser degree in the Tochi valley of the northern Waziristan Agency, both of which tracts have been brought to some extent into line with British districts and pay revenue, the King's writ applies in the Agencies only to those who have been born in British districts and are technically British subjects. The tribes are very wisely left to manage their own affairs themselves; but no offences are permitted on the British roads, and the efforts of our officers, in so far as they do not relate to these roads, are confined to preventing general tribal fighting that would tend to close the roads or to cause serious complications.

The population of the five British districts, according to the census of 1901, was 2,040,000 souls, and is probably now some 2,200,000. The density of population per square mile varies greatly; for the Province it is 113 persons, in the Peshawar district it is 249, and falls as low as 61 in the district of Dera Ismail Khan. In England it is 606 per square mile. What the population is between the inner and the outer borders it is impossible to state with any approach to accuracy, a census being out of the question. Taking the density of population in Kohat and Kurram, which are tracts that approximate closely to the conditions of the territory in question, and allowing for the vast uninhabited areas of the mountains round about Chitral and for the deserts of Waziristan, also for the relatively dense populations in Swat

and Tirah, I think an average of sixty persons per square mile is near the mark. If so, the population of the outer portion of the Province, 25,000 square miles in extent, is about 1½ million souls, which, at the rate of one in five, gives 300,000 fighting men. In some respects this sounds more formidable than it is; at no time, and for no joint purpose, could all this mass of men combine for collective action. drawn as they would be from innumerable different clans, torn by family and tribal feuds, living in a tangle of mountains, over a length of at least 600 miles of country, without a recognised head or leader, and jealous to the death of each other. Moreover, armed though they be, the hillmen have not the slightest wish to meet cavalry and artillery in the open. No doubt, in former ages they swarmed down for the loot of India. But this was in the wake of the regular invading armies of the day, and only to the tune of a few thousand tribesmen at a time. There is no instance of the fate of a battle or other event, or of the course of history, in India having been affected by the tribesmen as such.

In this long and narrow Province the question of good and rapid means of communication is of the greatest importance; chief among them is the railway. There is no such civiliser as a railway. The course of events a generation ago, trans-Indus, would without doubt have been very different if the railway had been pushed on to the limit of the Empire without delay; and it is difficult to believe that, whereas there were railways in India before 1857, it was not till 1881–82 that the locomotive appeared in Peshawar—it took over twenty-five years to arrive there from Calcutta. I remember the sensation its appearance caused among the hillmen; how crowds of Afridis used to stream down to Peshawar and squat all day, perched like crows, on every vantage point, watching the wonderful engines. Since that day there has been good progress. After the border war of 1897, a line, originally for military reasons, was laid from Nowshera to the foot of the Malakand Pass. It has developed into an artery of commerce to an extent that justified its conversion from a narrow to a broad gauge. The railway, which crosses the Indus at Kalabagh, and, *via* Kohat, reaches Thull at the end of the Kurram valley, has greatly stimulated trade. A third line to the base of the hills is under construction; it will be taken over the Indus at Kalabagh and carried to Bannu. It is intended to tap the local trade and open the coalfields that I have mentioned. When the Thull railway has been extended to the head of the Kurram valley, when a short line has been constructed in the Hazara district and a lateral branch been provided from Bannu to Tank and Dera Ismail Khan, the Province will be well equipped with rapid means of communication. In their way, Pathans are keen business men; they are fully alive to the benefits of railways, and the running of trains to Bannu is eagerly awaited by the people of the district and their neighbours, the Wazors. In a wild country a railway has, by the way, a powerfully sedative effect, which all makes for peace and order. Railways are for us what roads were to the Romans. With the latter the Province is not badly provided. In this connection it may be well to emphasise what has been done by the British Government for trade with Afghanistan and Central Asia during the past two decades. Prior to 1878 this trade found its way between India and Afghanistan—the one a fully and the other a comparatively settled State—as best it could through the belt of independent territory that intervenes, and its best was bad. A little traffic trickled, over the roughest mountain paths, through the disturbed tribal limits of Chitral, Dir and Swat, to the Peshawar valley. The Khyber had been closed for many years—in fact since 1817—and caravans plying between Peshawar and Cabul struggled through the arid and waterless Mohmand hills, crossing the Cabul river twice on their road, and paying such blackmail and escort money as the Mohmands could extort. The Kurram valley was certainly, in a fashion, open under Afghan rule, but the western portion of the Kohat district in days before 1878 was not safe, and in any case the trader had to march through sterile wastes all the way to Rawul Pindi before he touched the Grand Trunk Road, or, since 1879, the railway. The Tochi valley was absolutely shut. Till 1894 the Gumal route, which is the southernmost and, after the Khyber, the most important of the trade routes on this frontier, was annually the scene of embittered struggles between the Mahsuds and the Ghilzai traders who forced their passage down in autumn and up in spring, with their families, camels, and flocks of sheep. The Powindahs, as they are called, marched in large bodies of thousands, moving, like regular armies, through the enemy's country; women, children and animals in the centre, and fighting men in advance, on both flanks and in the rear; while the Mahsuds hung round them like wolves, cutting up stragglers and pouncing on camels and sheep. Occasionally

there would be a pitched battle with heavy losses when some particular cause inflamed the hatred of both sides. All efforts of the Powindahs to effect a *modus vivendi* by the payment of passage money were fruitless. This hardy race of merchants had for generations literally to fight their way through the passes. In 1878 the Khyber was reopened for trade; in 1892 the Kurram valley, which had been closed to traffic since 1880, came under British administration and became again a road for trade. Shortly afterwards, in 1894-95, the Chitral, Tochi, and Gumal routes were permanently opened to commerce. Since those dates, excellent metalled roads have been driven from the inner border to the western limits of the Agencies, peace and security are maintained by armed forces in the pay of the British Government, wrongs are, as far as is possible, redressed by British officers, and railways have already been, or are being, brought to the eastern terminations of the routes. It is no mean impetus to prosperity that we have achieved by establishing five secure lines of trade through independent territory. The total value of the trade which is thus facilitated is about £2,000,000 to £2,250,000 sterling, and would, no doubt, be much greater but for the fiscal policy which prevails in Afghanistan and Russian Central Asia. The Frontier Province must always owe its commercial importance to the fact that it lies across the great routes that connect the markets of India with Central Asia and Afghanistan.

Of the total area of 13,000 square miles comprised within the inner border, 6,000 square miles are unculturable, and only about 4,500 of the remaining 7,000 are, on an average, cultivated; this is owing to deficient rainfall and absence of a sufficient water-supply for irrigation. The unirrigated but cultivated area amounts to 3,200 square miles, chiefly in the Hazara district, where the rainfall is abundant. The total irrigated area is about 1,000 square miles, of which some 800 square miles are irrigated by canals. In this latter area it is gratifying that about 340 square miles, or over three-eighths of the total area under canals, owes its existence entirely to the action of the British Government. It is irrigated by the Swat, Cabul river, and Paharpur canals, which have been constructed by us. An additional and bold work is in course of execution, which will add a further 300 square miles of irrigation. The Swat river is being tapped in Swat itself, and the water will be taken by a long tunnel under the Malakand Pass. Where the tunnel ends on the southern face of the range, the fall will permit of an electric development of 20,000 horse-power, which will be available for industrial enterprise hereafter. This new canal will be finished, it is expected, four years hence. All this canal irrigation—which will extend to 1,300 square miles, of which 630, or nearly half, will have been created by the British Government—lies in the dry tract in which the average rainfall is less than 15 ins. in the year. The remainder of the canal-irrigated area in the Province is watered by small and very numerous cuts, which were made by the people centuries ago, according to a rough local system of levels, and which are managed by the people themselves. In the Peshawar and Bannu districts, where the pressure of the population upon the canal lands is enormous, the soil most fertile, and the supply of water somewhat scarce and precarious, the irrigation system is arranged on wonderfully intricate but admirably practical, just and efficient codes of irrigation rules; they go so far, in many cases, as to lay down the very hour during which a man may water his field, in rotation, every week or fortnight. These codes date from pre-British days, and are remarkable instances of how the pressure of a common need can compel the most quarrelsome and cantankerous of men to unite for a joint purpose. They have been recorded by the revenue settlement officers, and one of the blessings of British rule is that the frequent disputes over water-rights admit of swift and peaceable decision by the revenue staff; whereas in Moghul and Sikh days the season for irrigation was the time for busy sniping and battles among villages. Here water is gold to the cultivator; every spring, hill torrent, rivulet, or brook, the drainage of marshes, every drop of available water, is utilised with the utmost care, and no ruler is better remembered than he who has added to the irrigation supply of the people. Intimately related to this question is that of famine, the nightmare of India. Owing to the permanent nature of what irrigation there is, and to the mobile and enterprising disposition of its inhabitants—the surplus of whom, instead of staying at home to the congestion of the consuming public, goes off without hesitation to seek an honest or other livelihood elsewhere—famine has never afflicted the arid frontier.

Cultivation, allowing for the laziness of Pathans, is much the same as in the northern Punjab, and so are the crops, excluding fruit. The climate and soil of the frontier are excellently adapted to fruit culture, and the export of fruit to India, which has been immensely developed by

the railways, amounts now to nearly 4,000 tons a year. Haripur, in Hazara, the Peshawar, Kohat, and Bannu districts are the principal fruit-growing centres, and the local government is paying much attention to the advancement of this very profitable branch of cultivation. The land tenures, in so far as they do not relate to Pathans, are similar to those in the north of the Punjab. The Pathans hold the largest amount of land in the Province; almost exclusively in Peshawar, Kohat, and Bannu; they possess a great part of the land in Dera Ismail Khan, and only in the Hazara district are they in the minority of landowners. With them the tenure of land is based upon the clan-system. Every true-born Pathan must belong to a tribe, and within the tribe to a clan, and within the clan again to one or other of its sections. Each tribe occupies a certain definite area, and to each clan and section thereof is told off a defined portion of that area. Every member of a clan has a fixed share in the clan holding; that share is his hereditary portion in the joint weal or woe. The shares of the families may all be equal, they may be unequal; but whatever they have been, that they remain; and it is in no man's power to alter his share as of right except by the unanimous consent of all the shareholders concerned—that is to say among Pathans, never. But land owned according to ancestral shares may be and is constantly bought and sold; and it can very well happen that a man has ceased to be a land-owner and yet possesses a potential share which, if his section should acquire fresh land, comes instantly into active operation. It follows that clan landowners hang together; it is not easy for outsiders to acquire land among their holdings, which fact, coupled with the pre-emption law, explains why there was no need for the Land Alienation Law where the Pathans are strongest. Logical concomitants of this system are that, in fairness to all the shareholders, each should have his allotted portion of good and bad lands, and that from time to time a redistribution of the sectional or clan or even tribal holdings should take place. This latter process, called the "vesh," or distribution (of lands), by lot generally, has been adduced as a proof of the Jewish origin of the Afghans; it is nothing of the kind, but is a phenomenon which is not uncommon in the early land tenures of many European nations who are without doubt not descended from the Lost Ten Tribes. As the "vesh" is obstructive to improvement in agriculture, it has been stopped long ago in British districts. It is still in force in some parts of independent territory, where it is rarely accomplished without bloodshed. So inherent is the share system in the life of Pathans that for a man to prove that he is a Pathan it is necessary or sufficient, as the case may be, for him to establish that he is entitled to a share in a clan-holding; if he is, then the rest follows *ipso facto*.

Of the population in the five districts, 92 per cent. are Mohammedans, and nearly one-half are Pathans; the rest are mainly of Indian stock. Beyond the inner border probably 99·5 per cent. are Mohammedan, and over 80 per cent. are Pathans. In the districts, especially trans-Indus, the Pathans are unquestionably the dominant race. They are all Sunnis, and the fact that the Turis in Kurram and a few clans of Orakzais in Tirah are Shiahs indicates either their non-Pathan origin, or the fact that they are descended from former adherents of the Roshaniya sect, of which more presently. By the force of circumstances they probably turned to the Shiah faith when the sect was rooted out, rather than join their Sunni persecutors. Of languages in the Province there are many, corresponding with its conglomerate of races—the *débris* of many a people and petty state which have been swept aside or submerged by the successive streams of invasion. In the north the tribes of the Chitral glens preserve ancient languages that have nothing in common with neighbouring tongues except an Aryan origin. In the inaccessible highlands of the Swat valley and the defiles that flank the Indus, other aboriginal relics speak little known languages. The Gujars, or cowherds of Swat, Dir, Buner, and the high ranges of Hazara still use an old Indian dialect which is believed to have been the language of the former Gujar kingdom that collapsed many centuries ago. From Dir southwards to Dera Ismail Khan, "Pakhto," or "Pashto," the language of the Pathans, holds a supreme linguistic position; it is spoken by all the residents of independent territory without exception, and by over 1½ million people in the districts. Below Pakhto, so to speak, in the districts are two distinct variations of Punjabi; the southern one, spoken principally in Dera Ismail Khan is specifically known as Jatki. Finally, in the heart of the Mahsud country, and surrounded by a Pathan tribe, a small colony of traders and artisans speaks a little-known language called "Urmuri." It is quite unconnected with Pakhto, is spoken nowhere else but in a valley near Cabul, and of

it one can at present say no more than that it is probably Iranian. "Pakhto" itself is undoubtedly an Aryan language, which goes far back to the distant days when different branches spread from the parent stem. Very few works have been composed in it, and those that do exist being little read, it is practically an illiterate language, and is spoken with perfect grammatical accuracy by every true Pathan.

Although there are local and tribal differences of pronunciation, and occasionally differing words are used for household and agricultural implements and other subjects of that kind, all Pathans understand each other without difficulty. There are two classes of pronunciation rather than distinct divisions of the language, viz., the hard and the soft, the characteristics of which are well exemplified in the two forms of the name for the language, "Pakhto" and "Pashto" respectively. A line running east and west, roughly along the Thull-Kohat railway, divides the two; to the north of this line the hard variety is spoken and the soft prevails to the south. Pashto is an occasionally harsh, but virile, expressive and sonorous tongue, which lends itself very well to political oratory--witness those who have been obliged to assist at the interminable arguments and harangues in "jirgas," or tribal parliaments.

Naturally on the frontier, among a population inured to arms and long accustomed to view all learning with contempt, if not with horror as regards Western learning, preferring the sword to the pen, education is not in an advanced condition. It is significant that in the Province the percentage of Mohammedan boys at school, to those of school-going ages, is 12, as compared with 45 and 27 in the case of Hindus and Sikhs respectively. As may be expected, female education is at a low ebb. Nevertheless, education is making steady progress; it is stretching beyond the inner border. Schools have been established in the Khyber, Kurram, and Tochi Agencies, and there are signs that the Mohammedan community is awakening to the value of letters; there is a general desire for the extension of educational facilities. Last year, for instance, the people of Kurram petitioned Lord Minto, on his visit to that valley, for the grant of a local high school. But most encouraging of all is the deep and general interest which is being taken throughout the Province in the creation of a college at Peshawar, to be called the Islamiya College. It is proposed that instruction shall be given at it in both Oriental and Western learning, in Mussulman theology as well as in modern literature and science, thus satisfying the educational aspirations of all sections of the population. It must be borne in mind that we have to contend not only with the educational inertia which is inherent in a people of warlike peasants, but have to overcome also the positive dislike, and at times hatred, which many of the powerful class of mullahs and their followers—the old school, in short—entertain for Occidental education. As a civilising and humanising agent in a country where that is a special and peculiar want, there can be no two opinions regarding the incalculable value of education. And I am glad to be able to state that the past thirty years have witnessed a complete revolution of opinion among the local upper classes in this matter. Whereas in the seventies of last century it was an exception for the sons of leading gentlemen to attend modern schools, and such a thing as an educated youth hailing from beyond the administrative border was unheard of, the reverse is now the case. Khans and Maliks, the gentry, strive to give their sons a good education, sending them to Lahore and Aligarh, as far as England occasionally, for the purpose. The Islamiya College is intended to bring to frontier doors the highest and best form of education, short of a university training. In the course of time it must exercise a most powerful influence for good, both in the settled districts and in the wild country to their west.

Between sixty and seventy dispensaries within and without the inner border, gratuitously minister to the medical wants of the people, an aspect of benevolence in administration which they duly appreciate. It may not be fully realised what we do in that direction in India. Everywhere over that vast Empire all persons can, if they like, obtain gratuitous relief at a hospital or dispensary within a reasonable distance of their homes. There is no such thing in this country, or, on so huge a scale, anywhere else in the world. That this should be provided by a Government for and on behalf of 250,000,000 of people is an astounding fact, and one which is not sufficiently recognised by some critics of our Indian administration. Speaking of the frontier, it is right to acknowledge the great work which is being done by the mission hospitals at Peshawar, Bannu, and Dera Ismail Khan. They are thronged with patients from all parts of the frontier, and even Afghanistan, and ably and zealously aid the efforts of the official institutions towards the benefit of races whose surgical

operations are of the roughest, and whose indigenous physicians follow the weird prescriptions of the middle ages.

Of the early history of this part of the world little or nothing is known with any certainty till the campaigns of Alexander the Great brought Afghanistan and North India within the knowledge of the West. On his march to India he passed from Cabul through Bajour and Swat to the Indus, carefully avoiding the Peshawar valley, except where he crossed that river. From Strabo we know his sound reasons for doing so; he struck to the north because he had ascertained that it was the more habitable and fertile country, and enjoyed the best climate. In fact, he did not descend to the Punjab till the rains had broken. Parenthetically let me draw attention to the excellence of his Intelligence Department, the most striking proof of which is apparent when his army refuses to advance any further; in the heart of the Punjab he is confronted with the necessity of marching an army 2,000 miles to the Euphrates, and is instantly able to make up his mind by what routes to accomplish this astonishing feat; not without privations and difficulties, it is true, still with success. It is clear that Alexander found the northern portion of the Province thickly populated by Indian races, who, under a settled government, had enjoyed a fairly high civilisation, which presupposes a long period of order and tranquillity. His advent did not mean ruthless destruction as practised by Turkish and Mongol invaders, but the substitution of one set of rulers and one form of government for that of another. When the East had recovered its equilibrium after his death, we find first the Buddhist dynasty, of whose members Asoka, the first Emperor of India, is the principal, and then Greeks, in possession of the parts that Alexander had traversed between Cabul and the Jhelum river. The Greeks lasted for 200 years. They governed doubtless after our fashion, the chief civil and military officers were Greeks, the coinage, and no doubt the official language, were also Greek, but the people were not touched, and appear to have lived in tranquil security. Greek artists during this period and after it, materially influenced the native sculpture and architecture; had there been strong antagonism between the few Greeks and the many Indians this would hardly have been the case. To the Greek kings followed a succession of rulers from the north, who have been variously identified as Huns, and Kushan and Scythians. Whoever they were, they were civilised themselves or else rapidly assimilated the civilisation existing on the spot, for it is evident that their assumptions of power were not associated with cataclysms. Even if we had not the testimony of the eye-witnesses mentioned below, the mass of still extant ruins of monuments and villages, the roads that were cut by the Buddhists over the Kohat and Malakand Passes and exist to this day—the latter was actually used by our troops at the storming of the Malakand in 1895—the rock-engraven edicts of Asoka which can still be read in Hazara and Peshawar, all proclaim that the country from Chitral to Bannu and from the Jhelum to Cabul must have enjoyed protracted peace and order. The halcyon time must have lasted from before Alexander's day down to about the year 950 A.D. He found the Brahmins in power but Asoka established the Buddhist faith, which endured for at least 700 years. In the fifth, and again in the sixth and seventh centuries of our era, pious Chinese Buddhists were moved to go to India in order to obtain complete copies of the rules of Buddhist discipline. The pilgrims travelled to Yarkand, thence over the high mountain ranges, *via* Chitral to Jellalabad, Swat, the Peshawar valley, Tirah, Kurram, Bannu, and thence on to India. Their diaries give full contemporary information of the country with which we are dealing here. Everywhere they found the Buddhist religion in full force, the language of "Middle India," as they express it, prevalent, a dense population, peace and prosperity. Peshawar by that time had become a large city; close to it was the site of an immense monument, erected as a shrine over relics of Buddha, about 400 years previously by Kanishka the King, one of the successors of the Greeks. The pilgrim who describes it says: "The height of it was 470 feet and it was decorated with every sort of precious substance, so that all who passed by and saw the great beauty and graceful proportions of the tower and the temple attached to it exclaimed in delight, 'these are incomparable for beauty.' At sunrise the gilded discs of the vane on its summit are lit up with dazzling glory, while the breeze of the morning causes the precious bells that are suspended from the top to tinkle with a pleasing sound." Here, too, was the alms bowl of Buddha, of which the pilgrim records that the poor could fill it with offerings of flowers but not the rich. They mention also the gigantic tree associated with Buddha, which that insatiable sightseer, Baber, immediately went to see on his first visit to Peshawar in 1509. They

speak of an extensive monastery at the same place holding 700 inmates; this, too, then in ruins, was explored at much personal discomfort by Baber. All these have long ago disappeared, but it is a most interesting fact that, working on the diaries of the pilgrims, the head of the provincial Archæological Department, two years ago, discovered the actual precious relics. They rested in a cylindrical casket, 5 inches in diameter and 4½ inches in height, made of copper alloy, within which was a six-sided reliquary of crystal, 2½ inches by 1½ inches, having on one side a small hollow an inch in depth which had been sealed with the royal seal of Kanishka, bearing the device of an elephant. In this hollow were three small fragments of bone, which were believed by the builder of the monumental shrine to be relics of Gautama Buddha, and were undoubtedly deposited by him at this spot. The casket is ornamented in high relief with figures of Buddha, and portrait figures of King Kanishka with his attendants; other decorations in low relief are a long undulating garland of flowers upheld by little boys, and above it a highly ornamental band of swans flying with wreaths in their bills; these are beautifully modelled. Though the casket shows signs of artistic decadence, the influence of Greek art is manifest. To complete the interest of the discovery, the casket among its four votive or dedicative inscriptions bears the name of the Greek engineer who superintended the erection of the great monument.

By the seventh century Buddhism was fast on the decline, and in the ninth century Hinduism had re-established itself. In the next, or tenth, century begins the time of the Mohammedans. Ibn Haukal, who about 950 A.D. compiled a geographical account of the Mussulman world as then known, remarks that north and east of Sistan (then in Mohammedan occupation) lay Hindustan, meaning the country of the Hindus. From other sources it is known that Cabul was then a Hindu dependency. He mentions the Baluchis, but not the Afghans or Pathans; evidently the latter had not yet been converted to Islam. Towards the close of the tenth century a band of Turkish, Mussulman, adventurers from Central Asia seized Ghazni, and founded a principality which, under Mahmud and his successors, was to batter down Hindu opposition to the extension of Islam and to lead the way to the occupation of Northern India by various dynasties, some of Turkish, others of Afghan, origin, till with Baber rose the Moghul empire. The first mention of the Afghan race is met with in the eleventh century in the works of the Arab traveller, Alberuni. He visited India about the year 1010, and writes: "In the western frontier mountains of India there live various tribes of the Afghans; they extend as far as the land of Sindh, rebellious and savage races, people akin to the Hindus." About 1350 Ibn Batuta, another Arab geographer, notes that "Cabul was formerly an important city, but is now a village inhabited by Afghans. They hold the mountains and defiles and enjoy considerable power; the majority are brigands." He writes feelingly, seeing that the caravan which he accompanied was attacked by them. Attaching themselves to the Mohammedan invaders, the Afghans had become converted to Islam, and spread to the north and east, filling up the gaps due to the expulsion or migration of the Hindu population between 1000 and 1300 A.D. In the fifteenth century they were in considerable force round about Cabul, whence about 1460 A.D. a large body moved eastwards and commenced to occupy Peshawar and the adjacent valleys of Swat, Dir, and Bajour. In 1505 Baber speaks of Afghans in Kohat and Bannu, and near Peshawar, but in 1519 he found the bulk of the population in Bajour still non-Mohammedan. The troubles that followed his death gave the Afghans opportunities for further conquests, and, after the convulsions that attended the extirpation of the Roshaniya heresy in Akbar's reign, the main tribes finally settled down to the positions in which we still find them. This heresy is a peculiar incident in the local history. A Peshawar mullah who had wandered to Persia, Kurdistan and Asia Minor, set himself up as a religious authority at Peshawar about the middle of the sixteenth century, with the appellation of "Pir Roshan," or "shining spiritual guide." He abolished the Koran and preached a very advanced socialism. His doctrine spread among the tribes like wildfire. At one time he held Peshawar itself, and it was only after several religious wars had been waged by the faithful, with the aid of Imperial armies, that the heresy was extinguished with great slaughter. The struggle lasted for many years, during which the Afridis seized upon Tirah. This move was the last of the great tribal migrations.

What remains to be told of frontier history can be compressed into a few sentences. The administration of the Moghul, and after them of the Afghan, dynasty seems to have been tolerable, judged by an Oriental standard. The people were left to their devices so long as the general

peace was not broken; they held their own as well as they could against the hillmen, who had sufficient land at that time in their recently-acquired possessions, and did not feel the pressure of a growing population so much as they do now. Moreover, their surplus obtained ready service with a co-religionist Government. In spite of occasional disastrous collisions, things went fairly well. All this changed when the Sikhs supplanted the Afghan administration; there was naturally no sympathy whatever between governors and governed; the Sikh revenue system was as oppressive as it well could be; their draconic methods utterly failed to preserve order; and the hillmen who could, of course, no longer take service, fell to harrying the unfortunate country in the hated occupation of the Sikhs, who, in their turn, looked upon the former as a race under all circumstances for extermination, and sent them to the gallows upon apprehension. In the Peshawar district one chief actually held a grant from the Sikhs on the condition that he should annually produce twenty Afridi heads! Moorcroft, who passed through the district in 1824, notes that even Kashmir, miserable as it was, was not so desolate as the vicinity of Peshawar. Edwardes, writing in 1847, says that every two or three years the Sikh army harried the fields of the Bannu people, trod down their harvests, burnt their houses, and inflicted injuries which it took years to repair. In most parts of the Peshawar district the land taxes were collected by the periodical despatch of brigades. The Sikhs, in short, stood in the enemy's country, and acted accordingly. After thirty years of this veiled war we took over the frontier in 1849. The inheritance of misgovernment and maladministration was a serious one; it was comparatively easy to create order in the plains, but with the hillmen it was a different task, and it has taken fifty-six military expeditions to help towards that end. Although fifty-six expeditions in almost the same number of years sounds hopeless, an analysis of the figures shows improvement of late; in the first thirty years there were forty expeditions, but only sixteen in the second thirty years, and since 1901 there have been but two, each of the shortest duration—"week-end wars." It would be sanguine to build too confident hopes upon these facts; nevertheless there is some reason to conclude, as will appear later on, that the patient and steady work of sixty years has not been without results; the seeds of civilisation are germinating on the very stony soil on which they have to be cast. For the rest, the story of the five districts since annexation is one of peaceful progress; the population was exceptionally loyal during the Mutiny, and has been entirely untouched by the recent movements elsewhere.

Much has been debated concerning the alleged Jewish origin of the Afghans. On the one hand there is the strong tradition, which is universally accepted by the Afghans themselves; usually in such cases there is some, if only a slight, foundation for the popular belief. There is, too, the very unusual vitality of the Jewish race. On the other hand, everything else denotes the Afghans to be of Aryan descent. For many centuries they must have wandered, a pastoral race, in tents of black blankets, over the great barren plains and sterile ranges that lie between India and the fertile regions of Sistan and Candahar. It is quite possible that the Lost Ten Tribes were planted among, or found their way to, this race of nomads and were absorbed in them. When the irresistible Arab hosts advanced, a dim tradition of a Jewish element may have been revived and expanded to give to all Afghans, as such, a Semitic origin, and thus to place them more on a level with Semitic conquerors than were the Hindus. However that may be, I think there can be no doubt that the stock of the Afghans is homogeneous and Aryan. To the west they have been known always as Afghans—what that means no one knows; towards India they have always been called Pathans, from the generic name which they all use themselves when speaking their national language, viz., "Pakhtana" in the plural, and "Pakhtun" in the singular. The equivalent of "Pakhtana" is "Pathan" in Indian languages that are without the hard "kh." Theoretically, all Afghans are descended from a common ancestor, and ingenious attempts are made by their genealogists to dovetail into the national pedigree incorporated tribes and clans whose Afghan origin is, to say the least of it, doubtful. This is only the extension to the nation of the clan system, the essence of which is the actual or firmly-accepted traditional descent from a joint ancestor. How this acts in the tenure of land has been explained. It would be a mistake to suppose that this common relationship makes for concord—on the contrary, the character of the race and that terrible disintegrator, the blood-feud, keeps the clans ever disunited except under great pressure. Section is pitted against section; family wars on family; quarrels blaze up fitfully, die away, and are suddenly revived. In British territory,

of course, peace is kept; but the private vendetta flourishes as much as it dare. Briefly, the blood-feud is a debtor and creditor account of lives; blood demands blood. In theory, a murder can be compounded by payment to the injured, but since a composition is practically a confession of weakness it is seldom resorted to. One would think this state of things would be intolerable—to be shot, for instance, on account of what one's second cousin had done long ago; but a Pathan gives life as recklessly as he takes it. A feud is a source of pride, and an inexorable code of honour binds them in its iron grip. The necessity of exacting full revenge by retaliation is the evil of this code, its better side lies in the imposition of the equally sacred duties of an inviolable asylum to refugees; of the protection of dependents at all hazards; and of an open-handed hospitality. But this does not necessarily imply that you may not rob the stranger when once he has left your gates.

The civil constitution and the character of Pathans are obviously best seen in the natural state among the tribes of the hills; in the plains both have been much modified, a settled government has taken the place of self-government, and the character of the people has altered in some respects, partly to its advantage and partly to its disadvantage. The constitution of a Pathan tribe in the hills is the purest democracy; every adult clansman has equal political rights, and can, if he chooses, attend the tribal council in which is vested the power of the tribe or the tiny republic. Consequently, in important matters affecting large tribes, a council or jirga may be an unwieldy mob of up to 4,000 men. More usually, however, the tribe is content to let a smaller body act for it, and the jirga is composed of relatively few delegates, not representatives, who are selected by an informal process of popular choice. As the decisions of a jirga to take effect must be unanimous, it can be imagined what endless talk and discussion precedes a conclusion. But once they have made up their minds, the jirga, or rather the whole tribe, acts with great promptness. As against outsiders the jirga system operates fairly well. It is when we come to internal government that it breaks down. Theoretically the jirga should preserve general order and redress wrongs, but the latter only when appealed to, for every man has the right of private redress. As a matter of fact, the intestine factions and jealousies, the blood-feuds and incessant quarrels paralyse the power of the councils. It comes to this, that might is right and every man must look to himself, with the help of his nearest agnate relatives and such others as he can pay or persuade to join him. If he has no relations and friends he is in bad case indeed. It is, therefore, a source of congratulation to have many brothers, sons, and first cousins, second cousins are more doubtful; and the word to express a distant agnate relative is synonymous with enemy. Now put arms into the hands of every adult and one can realise the pandemonium—crime, violence and lawlessness are rampant within these republics. The wonder is not that offences occur on the border line, but that it is not always in a blaze. Of crime, in the Peshawar district, a British judge who knew it well, has written: "The principal crime with which we have to deal is murder—murder in all its phases; unblushing assassination in broad daylight before a crowd of witnesses; the carefully-planned secret murder of sleeping victims at dead of night, when often the wrong man is killed; murder by robbers; murder by rioters; murder by poisoners; by boys and even by women, sword in hand." Perhaps a rather highly-coloured picture, for, after all, in a population of over 800,000 souls, the annual number of murders is about one hundred. But it correctly depicts the condition of independent territory, where, moreover, the hired assassin flourishes. For £20 or £30 he will undertake to kill you any man; if he himself is killed red-handed the matter is at an end; if he escapes and names his employer, the blood-feud rests on the latter, and the agent is no more blamed than is his dagger. It is quite a reputable pursuit, and one at least of the profession, the well-known Chikkai, reached a high eminence of wealth and respect.

The character of the Pathan is a strange blend of virtues and vices—hardy, brave and proud; active in their habits and simple in their lives; frank, ready to die in obedience to their code of honour, yet often faithless and treacherous; generous to a degree and devoured by a greed for money; capable of great endurance and feats of energy, but constitutionally lazy; merry, cheerful, fond of music, sportsmen all, yet with a vein of sour austerity running through the nation. Envy of their fellows, instability of purpose, a suspicious temper, intense jealousy, bitter vindictiveness, excitability, and want of self-control are prominent faults. They are capable of strong personal attachments, and never forget a wrong. Grossly superstitious, credulous and bigoted, they know little of their religion, and will not permit their mullahs to interfere with their customs; but if danger

threatens from a foreign foe nothing is easier for the mullahs than to kindle a widespread fanaticism and to unite the clans under the leadership of the church. Impatience is a marked characteristic; Pathans understand and can take staggering blows, but nagging drives them mad. They highly appreciate justice, an open hand, firmness, patience, good humour, and the disposition that punishes and is friends again. They are great travellers and keen observers, shrewd men of business, good traders, indefatigable in the pursuit of gain, intellectually wide-awake, of active mental ability, and ambitious to a degree. The race is a mass of contradictions, which are accentuated by their strong individuality.

I have said that the border-land is a problem of surpassing interest and grave importance. A seething congeries of hungry clans had for generations been the terror of the peaceful cultivators in the plains, a border-line of hundreds of miles in extent had been exposed to their attacks when it fell to the British to tackle the problem. Slowly and patiently, but not without success, has that task been persevered in. We commenced by expeditions all round; the tribes unacquainted with our strength provoked coercion, and it was liberally applied, as was indeed necessary and advisable. At the same time, unconsciously following Roman precedents, clansmen were freely enlisted in the army, an outlet being thus provided for adventurous spirits and for some of the surplus population.

The next step came when in 1879–80 a body of tribesmen, now the Khyber Rifles, was formed by Government to keep order at their own homes. Presently it was recognised that the one thing, from a political point of view, to which the tribes are passionately attached and for which they will fight to the end, is their internal or domestic or municipal independence. It was also realised that although British laws and law courts, legal procedure, the police and revenue systems are excellent institutions in their proper places, it was not expedient to press them upon a people out of season. Accordingly, when Kurram was occupied in 1892, the Khyber experiment having proved a success, a local Militia was raised and the people were promised that they would be allowed to follow their own unwritten laws and manage their affairs themselves under the general superintendence of British officers, provided that the general peace was observed and British interests were respected. Subsequently, in Kurram, after the people had enjoyed general peace, and when they began to appreciate the comfort and attractions of security of life and property, a few British laws were applied to them, principally in the direction of the suppression of grave crime, at their own request. That is a very important point. When people ask for a thing they want it. Here again we were virtually proceeding on Roman lines—the Roman kept Roman laws, Roman rights and obligations, privileges to which the provincials might attain, as favours. In the other Agencies which have come into being after the Khyber and the Kurram valley were occupied, the same principles obtain; British supremacy is maintained by British officers, general order is enforced and British interests, including, of course, those of British subjects, are upheld, but otherwise the people are left alone. Insensibly they become accustomed to the benefits of tranquillity and order, almost without knowing it they are introduced to civilisation. I am sure that in this lies the solution of the problem; wherever in the border land we are compelled to hoist our flag, let it mean a general peace but not an interference with the self-government of the people. Once they are certain in their minds, and the difficulty is to convince them, that we have no intention of applying hated laws and detested systems, they welcome the general peace which saves them from collective disaster, and are glad enough to enjoy their own in their own way. At the same time the assumption of control brings with it the obligation of considering the material interests of the tribes. The chief question here is summed up in the one word—food. The population increases, not so fast as it might, owing to the diligent killing that goes on, but still it increases; land in the hills is limited, and what are the clans to do? Their native bent is towards robbery and raids. If this congenial means of livelihood is cut off, something else must take its place. As to this, enlistment in the army continues, and in addition the various corps of Militia and levies afford service to some 7,000 tribesmen. It has been explained what has been done for trade among them, and how facilities have been afforded for more peaceful migrations to India than were indulged in by the forebears of the borderers. And if in the areas about to be irrigated by the great canal projects now being undertaken or considered in the Punjab and Sindh, portions can be reserved for the hillmen, a step will have been taken with far-reaching consequences towards the pacification of the border. Doubtless there are difficulties in the way but we have surmounted worse in India, and have been the better for it.

It may seem rash to say, when we frequently hear of offences and sometimes of expeditions on the border, that a change for the better is coming, but the symptoms are unmistakable. The record of military expeditions shows that the use of force is more rare. This is significant, though too much reliance cannot be placed upon it, since in view of the recent arming of the tribes, we may have at any moment to re-assert our strength. But other indications of the change are plain. Thirty years ago the Black Mountain tribes were a perennial source of trouble; now the border of Hazara is the most peaceable section of the frontier. The Gaduns, the colony of Hindustanis, Buner, and the other tribes on the right bank of the Indus were a constant anxiety to the authorities at Peshawar. Lately these tribes took an eminent archæologist into the heart of their country in quest of Alexander's Aornos (which everyone will agree with him was not on the Indus, and probably lay in Swat). Who that fought on the Malakand in 1897 could have dreamt that drills worked by electricity would soon be boring a tunnel under the battle-ground, and that within fourteen years of a fierce rising of fanatics the chiefs of Lower Swat would be subscribing towards the establishment of a Lady Minto Female Hospital in their midst? Officers with small escorts travel in perfect safety to Chitral and back, where fifteen years ago such an attempt would have been certain death. In the Khyber an alternative road has been made by tribal labour alone. Up and down the frontier the most exposed positions are held by Militias drawn from the tribes themselves. A very notable instance of this change is that of the Kohat Pass; at either end of it lie the important garrisons and civil headquarters of Peshawar and Kohat, which obviously should be connected by a metalled road. Time and again, attempts to construct this road were baffled by the stubborn opposition of the tribesmen. They thought if the road came that their internal independence would go. Some years ago the case was put to them again; an officer whom they trusted implicitly—and Pathans are specially susceptible to personal influence—was able to convince them that this would not be the case; they accepted the road, helped to make it, and where formerly one had to pick one's way on horseback over the boulders of a torrent bed, one motors now in a couple of hours from Peshawar to Kohat.

It may be optimism: I can only tell you what in the course of thirty years I have seen myself, and that induces me to say that there is no ground for discouragement. Our aims should be to remove deep-seated suspicions, to punish thoroughly where deserved, then resume friendly relations, patiently persevere, and, above all things, civilise; we shall thus in the end solve the problem and succeed in the accomplishment of our task.

DISCUSSION.

The CHAIRMAN said he was sure all had listened with the deepest interest to Mr. Merk's paper. No one was better qualified to tell the story of the North-West Frontier Province. He had referred to the romance of the frontier, and its great attractions, and to the splendid names which had been connected with its history. Wild and sterile as the country was, it certainly had a charm which must appeal to everyone who had any spirit of adventure in his composition. It was the field of opportunities for young soldiers and young political officers; and his lordship could assure his hearers that many such were now gaining laurels which were unknown in this country, but which would be brilliantly recorded in history. Mr. Merk had alluded to the great advance in civilisation which had taken place generally on the frontier. He (Lord Minto) went out, in 1878, to join Lord Roberts. The railway then went only as far as Jhelum, and it was necessary to proceed, by long tonga drives and long marches, across the Indus, and on to Kohat, and then, by rough roads very open to attack, to Thul and up the Kurram. But when there the other day his lordship found the railway to Thul, and an excellent road to Parachinar, and the country looking full of prosperity. Moreover, the party came back in one day in motors from Parachinar to Kohat, and over the Kohat Pass to Peshawar. That was a marvellous change to those who knew the country thirty years ago. At the latter date one rode through the Kohat Pass at some little risk, but now one drove through comfortably in a motor. There is now a small factory of arms in the Pass, and on his recent journey one of the motors broke down, and in a few moments there appeared from this factory men who seemed fully acquainted with motor machinery. The same kind of change was seen on the other side of Peshawar. Not long after his arrival in India, his lordship visited the Swat Valley, and the only request made to him by the tribes was for the doubling of the railway line to Dargai, as the present haulage power was insufficient. The civilising power of railways was simply enormous; one saw it on all sides. Some people were nervous about the increase of railways, on the assumption that they might mean unjustifiable advance. But his own opinion was that railways would diminish the number of expeditions beyond all expectation. They brought people into touch with one another; they enabled the frontier tribes

to know us and trust us. Mr. Merk said the Pathan has commercial tastes, and knows very well what improved transport means, and that it would put more money into his pocket. It was working on the right lines to develop the railways not in a strategical, but in a commercial sense; they would exert greater civilising influence than anything else. Civilisation was bound to advance, and it would do so more quickly by commerce than by arms. Though we were yet a long way from the Durand frontier, he supposed that as years went on British administration would probably extend to it, and he hoped that would be feasible without innumerable expeditions; because, though he was very far from saying that expeditions were all over, they had certainly largely diminished, and the chances were that they would diminish more in the future. Mr. Merk alluded not only to better means of communication with regard to railways, but to the circulation of news which had taken place on the frontier; and that, his lordship thought, was having a very great effect. The tribesmen get news of all that is going on in India. In the Swat Valley he was talking to an old warrior who fought against us in 1897, who said, "I have been reading the papers, and I see you have trouble in Bengal." His lordship said, "Yes, there is a little trouble there"; to which the tribesman rejoined, "Why don't you send me and 400 men there? I would soon put it all right." He feared the treatment might have been a little crude. Still it showed how news was being circulated. The Amir got his Reuter's telegrams as regularly as did any official in India. On the whole the circulation of information was telling in the right direction. There was, however, another side to the picture. The enormous increase of arms was a disagreeable factor we could not ignore, though he agreed with Mr. Merk that it required special circumstances to unite the frontier tribes. They were much better armed now than in 1897; they possessed many more arms of precision; and if a common cause were to unite the tribesmen the danger to us would be greater than it was a few years ago. But the advance of civilisation had gained the upper hand, and he regarded the future as decidedly hopeful. The development of canals was also offering enormous opportunities. No one had realised the situation more than had Mr. Merk, particularly on the Bannu frontier, where the Mahsuds, who were not easy people to manage, had depended largely on plunder, and if that plunder was rendered impossible by the excellence of our administration what were these poor people to live on? If we could give them irrigated lands and increase their service in the Army, we should be going a long way towards solving the difficulty. In the Swat Valley the boring through the Malakand Pass, and the consequent development, not only of irrigation, but of vast electrical power was a marvellous feat of engineering. He thought this country should be proud of all that was going on on the North-West Frontier, and he regarded the future as full of promise. In conclusion, he could not say how grateful we should be to our frontier officers, of whom Mr. Merk was a brilliant representative.

The Right Hon. Sir MORTIMER DURAND, G.C.M.G., said he would take the hint given by Lord Minto to intending speakers, and be brief in his remarks. But, as he had been called upon, there were a few words he would like to say with regard to the interesting and very encouraging paper given by his old friend, Mr. Merk. He regarded it as very encouraging because he had seen Mr. Merk's work on the frontier, and knew how well fitted Mr. Merk was to tell us what was the real condition of affairs. The point which he (Sir Mortimer) wished to bring out was this, that the peace and prosperity of the North-West Frontier was not only a good thing from a local point of view, but concerned the very much more important question of Imperial defence. He had no desire to criticise recent conventions, or to express distrust of friendly nations. Nevertheless, it should be remembered that the security of India must always depend, not upon any agreements with foreign Powers, but upon our being so strong that no one would care to attack us. And nothing would add more to our strength than a thoroughly pacified borderland, organised for defence. Mr. Merk had shown that our frontier policy, slowly evolved from many conflicting policies, was proving successful, and that the borderland was in fact being pacified, and brought under effective control. There was, therefore, good reason to hope that, although we must still expect occasional trouble from the tribes, the belt of rugged mountain territory on our North-West Frontier would eventually be not a source of anxiety but a great barrier against aggression, a substantial addition to the security of India. That was the chief value of Mr. Merk's paper, and that was why he had listened to it with so much pleasure.

Sir THOMAS HOLDICH, K.C.M.G., K.C.I.E., C.B., congratulated the author on his lucid account of the frontier. One could not have a better authority on any matters connected with the frontier touching things commercial or judicial, or even criminal — in fact, he might say, especially criminal. For he remembered, many years ago, when he was with Mr. Merk at Peshawar, that the walls of his bungalow were decorated with a very gruesome array of murderers' knives; and if those knives were not actually dripping with gore, they were suspiciously unclean. They bore testimony to the flourishing condition of that particular branch of Pathan industry. With regard to the statement that the Afghans were of Jewish origin, that required a word of explanation; for if one addressed the Semitic Afghans with the statement that they were descended from Jews there would be trouble, for they hated and despised the Jew as much as their ancestors, the Israelites, did. Many arguments might be adduced on both sides, but so far as he knew the Durani Afghan had some

right to the claim to be descended from the Children of Israel. The name Afghan was Armenian, signifying simply a man of the hills, and that gave the clue at once to the tradition, inasmuch as the Israelite tribes were carried captive by Sargon to Armenia. Another point which came out of the paper was the arming of the tribes on the frontier. Everyone agreed that the tribes were now much better armed than they were a few years ago. One asked why they wanted these arms, and where they got them from? He did not believe that in the councils of any of the tribes of the frontier there was any idea of a serious invasion of India. Those tribes had reasons of their own for wishing for arms. When he was working hand in hand with Mr. Merk, on the Oxus frontier, each of them was supplied with an orderly from the 11th Bengal Cavalry. These men lived together, ate together, served together, and were very handy assistants. On one occasion, one of them helped the other out of a river when he was in danger of being drowned. Yet when the expedition was over, and it was time to dismiss the men, his orderly came to him and asked for a rifle. On being asked why, he said: "Because Merk Sahib's orderly has acquired a valuable rifle, and we have got to settle matters between us now that the Commission is over. We are going to our own country, and one of us has got to shoot the other, and he has all the advantage on his side." He (Sir Thomas) told him he could not give him a rifle, but in the end he gave him his revolver, with the strict injunction that he should only use it in self-defence. He took it away, and nothing more was heard of him. Thirteen years afterwards he (the speaker) was in the man's country, and he enquired whether the people recollected him. They replied, "Yes, we remember him well. Twelve years ago he was shot by Merk Sahib's orderly." That was the truth of the position. Just as we in England wanted more "Dreadnoughts" and more arms to assert our position in the councils of the European nations, so did the tribes in the hills require a similar power of asserting themselves. Rifles were turned out in thousands in the factory of the Amir of Afghanistan, but they were for his own people; he (the speaker) never saw Afghan rifles on the frontier. Occasionally they were stolen from our people and carried across the frontier. There were times when one could purchase service ammunition across the border considerably cheaper than in India; but he thought those times had now gone. The chief source of supply was undoubtedly gun-running. With regard to the latter, Mr. Lovat Fraser had told us all about it. He showed that the trade was British, British in its inception, British in its continuance, though France, Belgium, and America had all cut in more or less. The trade was very lucrative, and whilst that was so it would be very difficult to stop it. There were still steamers plying in the Persian Gulf in connection with that trade. He would like to know Mr. Merk's opinion of how those rifles were paid for. Undoubtedly they were partly paid for by rupees furnished from the Indian Treasury in the form of subsidies. Thus we supplied arms at this end, and paid for those arms at the other end; and yet we came down heavily on the Arab sailors who ran their dhows across the Persian Gulf, and on the leaders of the Afghan caravans who conveyed those arms across the deserts of the Persian frontier. That created a position that was certainly illogical.

General Sir Alfred Gaselee, G.C.B., said he felt it a great privilege to bear testimony to the very able paper which had been read. The sentiments he had intended to express had been largely forestalled by Sir Mortimer Durand, and also partly by Sir Thomas Holdich. Mr. Merk said that we had 300,000 armed men, or men capable of bearing arms, men who were hardy, inured to warfare, and brave. Amongst themselves those men were without any definite control, and it had been said that they were not easily induced to take up arms in any quarrel of their own. But they had also heard that there had been, on the frontier, fifty-six expeditions—extending over, it was true, a good many years. Special mention was not made of the big expedition in 1897–8, when we had 50,000 troops mobilised. That was a very big affair, and if we had been occupied in any other part of the world at the same time it would have been a very serious matter indeed, and would have gone a long way towards crippling us. We had an experience of how brave and unorganised and undisciplined men could harass an army. That was before the days of the Boer War, which also taught us a great lesson. He was not an alarmist, but the situation on the frontier called for the earnest and careful thought of our statesmen and leaders. His impression was that the subject did not receive the attention it deserved. He did not believe that the Pathan bought his arms simply in order to shoot his neighbour, though that might be part of the reason. When it was remembered that nearly every man on the frontier was able to use a rifle, it showed that close watch and care should be observed.

Dr. M. A. Stein, in proposing a vote of thanks to the reader of the paper, said he considered it a great honour to do so, as Mr. Merk was a judge of unparalleled experience of the frontier. His (Dr. Stein's) studies drew his interest to the North-West Frontier long before he was able to go there, though that was twenty-two years ago; and though he had since been able to carry his travels and researches far beyond India, into Central Asia and China, he felt strongly drawn to the North-West Frontier, which was full of fascination to every historical student. He could not venture to touch on many points of history, as he feared he would detain the meeting far beyond the allotted time if he did; but one or two points had a direct bearing on the modern conditions with which they were that afternoon pre-eminently concerned. It was true that the North-West Frontier had always been the

gate of India, but it was all important on which side of that gate stood those whose function was to guard it. Nowadays this frontier and the tribes inhabiting it had to be watched with great care against the possibilities of invasion. Until the last century, that frontier had been really the advanced base for Powers which were not essentially Indian. Ever since the time of King Darius, when the frontier formed part of the Persian Empire, stretching down to the Mediterranean, this territory had been very closely linked in its history with Eastern Iran, and that fact was reflected by the population as it at present stood. It was not the result of chance migration. The Pathans, linguistically and anthropologically, were proved to be of Eastern Iranian stock. Mr. Merk, in his masterly survey, had not touched on the work done by recent administrators of that bulwark of India, and one could understand his feelings in the matter. But for one who had special opportunities for watching the work of frontier "Politicals" without yet sharing it, it was a privilege to be able to testify to the essential part which their personality has played in the success achieved by their administration. He (Dr. Stein) knew that the late Sir Harold Deane, that truly great "Warden of the Marches," had always been guided by a full appreciation of the past history of the frontier and of the ethnic features of its population. He hoped that these factors would always receive due recognition in future frontier policy.

Dr. Walter Saise said in reference to Mr. Merk's remarks on the connection of the Afghans with the Lost Ten Tribes of Israel it might be of interest to them to hear what the Amir of Afghanistan himself thought of the matter. When he (the speaker) was in Cabul, at the end of 1909, the Amir said to him, "Dr. Saise, take your notebook and write down what I say. We, the Ben-i-Israel, came to this country and conquered it. We converted some of the people to the faith of Israel; we killed some of the people; and others in the inaccessible mountains remained with their old religion. Cannot define that religion. Like that of the North American Indians. Went about troubling people; killing people! They were the Kaffirs. In the time of Osman the Arab (the fourth Caliph of Medina) Cabul was taken and we, the Ben-i-Israel, became Mussulmans. But we reverted to our Israelitish faith, and then in the time of Abdul Malik (the tenth Caliph), son of Merwan, and when Hoojaj was Governor of Iran (Persia), we were reconverted to Mohammedanism, and have retained the truth faith ever since." This would be about 700 A.D. That belief of the King of Afghanistan in his Israelitish origin was worth recording, even should it have small ethnographic value. He (Dr. Saise) was inclined himself, after a personal acquaintance with the Afghans, to consider there was much force in the reasoning of Sir Thomas Holdich—in that fascinating work, "The Gates of India"—that the Afghans are descendants of the Lost Ten Tribes of Israel. But be this as it may, he heard from the King's own lips that he believes he is descended from Israel, and all the Durani (the royal) tribes believe it also. Mr. Merk's reference to railways reminded him that his Afghan companions, among them the Mehmandar Bashi (a cousin of the Amir), on the way to Cabul, informed him that they did not like railways! They stated that before the railway came to Peshawar wheat flour sold at twenty-four seers per rupee. Now the price is six seers per rupee. "When you build railways," said they, "away go the food-stuffs to other countries and prices rise!" This view was held by most of the Afghans with whom he had conversation, and the subject was constantly cropping up, for he frequently reminded them he could get from Bombay to London by train and ships as quickly as they could travel from Peshawar to Cabul on ponies. He had great pleasure in seconding the vote of thanks to Mr. Merk for a most interesting and instructive paper.

Mr. Merk, in reply, said there was no doubt that the tribesmen were now better armed than formerly. They had increased their fighting strength in every respect save one, and that was the following: they have breech-loaders, and, unless they could manufacture their own ammunition, they would soon come to the end of their resources. But, apart from that, the arming of the tribes was a further reason for what he had suggested as the keynote of the policy which should be pursued, namely, to civilise. He expressed his keen appreciation of the vote of thanks, and for the interested attention of his audience.

Sir William Lee-Warner, G.C.S.I., Chairman of the Indian Section, in thanking Lord Minto for taking the chair, remarked that what his lordship had done in the five years of his rule, in a time of exceptional difficulty, history would record. All present felt great gratitude to Lord Minto for presiding so soon after his return home, and for the remarks he had made before a section which did its best to disseminate a knowledge concerning the great Indian Dependency.

The Chairman, in acknowledging the thanks, said it had been a great pleasure to be present to hear the admirable paper, which had been followed by an equally good discussion. He would always be glad to do anything he could to assist a discussion about Indian affairs, and to facilitate a better understanding of the Dependency among the people at home.

HOME INDUSTRIES.

State Insurance.—The debate on the second reading of the Insurance Bill has disclosed no ill feeling towards the measure, but some anxiety as to what might result from its becoming law in its present shape, and outside Parliament the anxiety is much more pronounced. Great interests are uneasy. At present employers of labour are not

loudly objecting—they are reassured by the experience of Germany—but it is significant that the resolution submitted to a conference of Friendly Societies for referring the Bill to a committee of inquiry, and which, as it originally stood, spoke favourably of the Bill, was amended so that it might be entirely neutral; the Trade Unions fear that the Bill may be prejudicial to them; the doctors, with whom it so largely rests whether the Bill, if it becomes law, is to work well, are holding great meetings of protest; and those who speak for the more helpless classes—the casual, the charwoman, the domestic servant, and the like—dwell upon the neglect of the Bill to give them adequate protection. The chief objections may be summarised as follows:—(1) The Bill is unjust, since the healthy and efficient will pay for the weakly and inefficient whilst receiving nothing, and women are barred when married; (2) there is inequality of sacrifice; (3) the classes most in need of assistance—the casual worker, the migratory worker, the small worker for no master—will be more or less outside the benefits of the Act; (4) unless the bill is amended, the remuneration offered to doctors will not attract competent men; (5) the effect on labour must sooner or later be unfavourable, since wages will be lowered, or staffs reduced, or prices raised; (6) a great impetus will be given to malingering, more especially simulated unemployment; (7) the Friendly Societies will be prejudicially affected by reduction of subscriptions, the managing committees and officers will be unable to do the work thrown upon them, and the risk of defalcations will be great, and will lead to State control that must affect the independence of the Societies; (8) doles of money emasculate, and there is grave risk that the scheme may revive some of the abuses of the old Poor Law system. These several objections to the Bill may be satisfactorily met, but one and all they are weighty, and will require exhaustive discussion in Parliament if the Bill is not to work more evil than it cures.

Textile Workers.—The General Secretary of the Amalgamated Society of Operative Cotton Spinners, who is also Secretary of the International Federation of Textile Workers' Associations—which meet in Amsterdam next month—has issued his annual report, which contains much interesting information as to the work of the organisation during the past three years. The secretaries of the English Trade Unions give particulars of the conditions in their own departments. Mr. Marsland, of the Operative Spinners' Association, gives figures which illustrate the difficulties passed through during the three years, 1908–10. The number of disputes dealt with at the central office was 487. To members out of work through bad trade and other causes the sum of £236,597 was paid. Members who had met with accidents in the mills were paid £17,067. The amount paid to members involved in strikes and lock-outs was £173,153. During the same period £2,041 was paid in grants to help other associations. The total expenditure for the three years amounted to £503,679. In many districts every spinner belongs to the Association, and where this is not the case the percentage of non-members is very small.

The Infliction of Fines, and Humidity in Mills.—The Secretary of the Northern Counties Weavers' Amalgamation reports that, taking the same three years, the total cost for strikes and stoppages of all kinds to the district Associations and the Amalgamation reached £276,346. For many years past there has been a system in the weaving department of inflicting fines for alleged bad work which has become so irksome that the workpeople have commenced an agitation for the abolition of all fines and deductions from their wages. There is also general complaint of the practice of about one-half of the weaving mills which use artificial humidity in order to make a "weaving atmosphere." Hot steam is sent into the sheds and ejected from pipes, or the air is sprayed with fine particles of water. The workpeople have taken strong objection to this practice, on the ground that it is detrimental to their health, and that it is mostly required in order to facilitate the weaving of inferior material. It seems that hot air is sent through the sheds even in the summer months, causing great personal discomfort and much physical prostration, and in the winter months the sheds are said to be heated to such an extent that many workpeople contract bronchitis and rheumatism. Some time ago the Government appointed a commission, which included representatives of the workpeople and employers, to inquire into the whole question. The inquiry extended over two years, and the report is expected in the course of the next few weeks.

The Northrop Loom.—Considerable apprehension is being felt by workers as to the progress of this loom. Its general adoption would bring the cotton weavers of Lancashire face to face with a very serious problem—perhaps the most serious they have had to reckon with in our time. Operatives are now working twelve, sixteen, and twenty Northrop looms each, and the number of looms of the Lancashire type worked by an operative does not average more than four for each weaver. It follows that the general adoption of the new loom would mean the displacement of a very large number of workpeople. It is not at all likely that the cotton trade will ever, even under the most favourable conditions, be able to expand sufficiently to absorb those thrown out of employment by the new loom, and it is not easy to find the solution of the problem.

The New Tulle Process.—A new process that is being worked at Fresnoy-le-Grand, near St. Quentin, bids fair to affect seriously the silk tulle industry. The new fabric is produced from the same raw material as artificial silk and dispenses with the weaving operators, the fabric being made directly from the ordinary artificial silk solution. The system is a modification of that of ordinary calico printing, but whereas in calico printing the object

is to transfer the colours from the engraving to the cloth, in the manufacture of tulle the printing paste is caused to coagulate in the engraving, and then removed from it as a continuous web. A large copper cylinder, much larger in circumference than the ordinary calico-printing roller, is engraved with a net pattern, so that if a piece of gauze or tulle or corresponding design were wrapped round it the fabric would fall into the engraved portion. A description of the process in *The Manchester Guardian* says:—"The printing 'colour' used, a fairly thick solution of viscose, cellulose in cupro-ammonium, or celluloid, in fact, the usual mixture used in the manufacture of artificial silk, is fed on to the roller from a trough arrangement fixed over it, not from a colour-box below it. The roller revolves slowly, and the surplus 'colour' is removed in the ordinary way by means of a 'doctor,' leaving the engraving filled with paste. This is then caused to coagulate whilst in the engraving by spraying the roller with some suitable solution—water for celluloid, zinc chloride for viscose, or dilute sulphuric acid for a cupro-ammonium solution of cellulose—the surplus liquor running off the cylinder into the trough beneath. The solidified artificial silk is then removed from the engraving in a similar manner to that adopted in the preparation of celluloid films, etc., and carried away as a continuous piece on an endless travelling band pressing against the cylinder. The engraving, after delivering its contents, is thoroughly cleaned by squirting it with water, and dried by means of a hot-air blast, and goes round to receive more 'colour,' the cyle of operations thus going on continuously. The French works has now thirty of these machines running, each capable of producing about fifty yards of tulle per hour. The cost of manufacture is said to be about three-halfpence per yard. The material is fairly strong, especially to tearing, and does not compare at all unfavourably with the ordinary woven goods. It is proposed to erect a works in Germany."

Bradford and Australia.—Mr. C. Hamilton Wilkes, who is His Majesty's Trade Commissioner for Australia, has expressed his surprise at the seeming apathy of Bradford. Mr. Wilkes has been paying visits to the chief commercial centres of the country. At Manchester and Sheffield he was welcomed, but at Bradford manufacturers and merchants, as he complains, ignored him. "The Bradford manufacturers," he says, "must be perfectly satisfied with the trade they do with Australia, as evidently they believe they know everything that is to be known about the conditions of trading in that vast continent." And yet, as Mr. Wilkes points out, the British imports of velvet and velveteens into Australia amounted in value last year to only £274,786 worth out of £1,094,262. Mr. Wilkes thinks there is something in this matter worth consideration by British manufacturers, but the Bradford Chamber of Commerce, when officially informed of Mr. Wilkes's intended visit, decided to take no action as a body, and many members expressed their opinion that Trade Commissioners can teach them nothing.

The Coronation and "Sweating."—Miss Emily Cox, who is chairman of the Manchester, Salford and District Women's Trades Union Council, expresses the fear that the Coronation preparations mean for some of the humbler workers sweated labour. Miss Cox says that a few days ago she found a Manchester handkerchief-hemmer at her machine, but the work on which she was engaged was not the usual long strips of handkerchiefs, but Coronation flags, and these flags are not paid for at the usual rates. Handkerchief-hemmers are among the worst paid of the home-workers of Manchester, but for this special work a still lower depth of sweating has been reached. Small flags are machined for less than 5*d.* a gross. For flags a yard long (two sides only to be hemmed) the machinist is paid 7½*d.* a gross, and out of this she has to supply cotton, which costs over 2*d.* for the one hundred and forty-four flags. Thus for two hundred and eighty-eight yards of machining, and for the finishing, folding, and carrying to and fro, she receives about 5½*d.*, and she must work on Sundays as well as week days to earn enough for her rent, and the ever-shrinking pittance that goes for food.

OBITUARY.

Sir Charles Alfred Elliott, K.C.S.I., LL.D.—Sir Charles Alfred Elliott died suddenly, from syncope, on the 28th May, while he was attending communion service at St. Paul's Church, Wimbledon Park. Born in 1835, he was educated at Harrow and Trinity College, Cambridge. In 1856 he passed into the Indian Civil Service, and served through the Mutiny in 1857–8, receiving a medal and being mentioned in despatches. After holding several minor offices he was appointed Secretary to the Government of the North-West Provinces, a post which he held from 1870–5. In 1877 he became Famine Commissioner in Mysore, and in the next year Secretary to the Famine Commission presided over by General Sir Richard Strachey. He was then selected to organise the Census of 1881, but before this task was completed he was appointed Chief Commissioner of Assam. From 1886–7 he was President of the Finance Committee, from 1887–90 Member of the Executive Council of the Viceroy in charge of Public Works, and from 1891–5 Lieutenant-Governor of Bengal. After his return to England he served on the London School Board, and as Chairman of its Finance Committee up to the time of its abolition by the Act of 1902. He was created K.C.S.I. in 1886, and LL.D. of the University of Edinburgh.

Sir Charles became a member of the Royal Society of Arts in 1896. In the following year he read before the Indian Section a paper "On Measures taken by Government for the Prevention of Famine in India," for which he received a silver

medal; and in 1905 he read a second paper on "The Indian Census Report, 1901." He presided at a meeting of the Indian Section in 1907, when Sir Edward Buck, K.C.S.I., read a paper on "The Applicability to India of the Italian Method of Utilising Silt," and he took part in discussions on numerous occasions. He was a member of the Indian Section Committee, and he made his last appearance at the Society only three days before his death, when he was present to hear the paper which is reported in this number of the *Journal*.

GENERAL NOTES.

PRIZE FOR ELECTRIC LAMPS FOR MINERS.—The sum of £1,000 has been placed by a colliery proprietor at the disposal of the Secretary of State for the Home Department to be offered as a prize for the safest and most efficient electric lamp or lamps for miners. The competition is open to persons of any nationality, and the lamps submitted must reach the Home Office Testing Station, Rotherham, not later than December 31st, 1911. Particulars of the requirements which the lamps must fulfil may be obtained at the Home Office. In judging the competition, regard will be paid to (*a*) the first cost of the lamp; (*b*) the cost of maintenance; (*c*) convenience in handling; and (*d*) he weight of the lamp when charged and ready for use.

THE QUEENSLAND SUGAR INDUSTRY.—Queensland is one of the great sugar-producing States of Australia, and practically all of the sugar consumed in the Commonwealth is grown and refined in this State and in the northern part of New South Wales. The leading feature of the industry is the number of small cane-growers engaged in it, who now supply cane to the central mills, of which they are proprietors, as compared with the large estate owners of the past. There are about 125,000 acres of land in Queensland under sugar cane. The estimate of the output of sugar for 1910 was 170,684 tons produced by white labour, and 15,492 tons produced by black labour. There are fifty-three sugar factories in operation in Queensland, employing over 4,300 hands and representing an investment of about £2,250,000. The chief enemies of the sugar cane are the cane grub north of the Tropic of Capricorn, and frosts in the south, also occasional fires.

NEW PORT AT BUENOS AYRES.—The Government of the Argentine Republic have decided to construct a new port at Buenos Ayres. The cost of this undertaking is estimated at 24 millions of piastres (paper currency).

THE FRENCH MATCH MONOPOLY.—The annual report of the Director-General of the State Manufactories in France, which has recently appeared, shows that the total receipts of the match monopoly in 1909 amounted to £1,600,000, an increase of £16,000 over the preceding year. The net profits were £14,600 in excess of the profits realised in 1908. The average consumption of matches per caput in France during 1909 was 1,146, representing an expenditure of a fraction over elevenpence. The ordinary wooden sulphur matches, which ignite by friction upon any surface, furnished 55·6 per cent. of the quantity delivered to the public; wooden safety matches, which ignite upon a special surface, 41·2 per cent., and wax matches, 3·2 per cent. The State purchased during the year £71,500 worth of foreign matches to supplement its own production. Employment was given to 834 men and 1,467 women, distributed among the six State factories, which are situated at Marseilles, Pantin-Aubervilliers, Trélazé (Maine-et-Loire), Aix-en-Provence, Saintines (Oise), and Bègles (Gironde).

MEETINGS FOR THE ENSUING WEEK.

TUESDAY, JUNE 6...Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. W. Watts, "Charnwood Forest and its Fossil Landscape."
Photographic, 35, Russell-square, W.C., 8 p.m. Mr. Demachy, "The Oil-Transfer Process."

WEDNESDAY, JUNE 7...Economics and Political Science, London School of, Clare Market, W.C., 5 p.m. Professor Sir John Macdonell, "The History of International Law since 1848."
Concrete Institute, 296, Vauxhall-bridge-road, S.W., 11.30 a.m. Summer Meeting. 1. Professor Beresford Pite, "The Aesthetic Treatment of Concrete." 2. Report of Committee on "The Testing of Concrete, Reinforced-Concrete, and Materials Employed Therein."

THURSDAY, JUNE 8...Concrete Institute, 296, Vauxhall-bridge-road, S.W., 11.30 a.m. Summer Meeting continued. 1. Mr. A. E. Corbett, "The Y.M.C.A. Building, Manchester." 2. Report of Committee on "The Standardisation of Drawings of Reinforced-Concrete Work."
Royal Institution, Albemarle-street, W., 3 p.m. Mr. T. Thorne Baker, "Practical Progress in Wireless Telegraphy."
Optical, at the Chemical Society, Burlington House, W., 8 p.m. 1. Dr. Ettles, "Sight Testing Apparatus." 2. Mr. S. D. Chalmers, "Zone Plates." 3. Mr. V. H. Mackinney, "A New Toric Machine."
Aeronautical, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

FRIDAY, JUNE 9...Royal Institution, Albemarle-street, W., 9 p.m. Professor Svante Arrhenius, "Applications of Physical Chemistry to the Doctrine of Immunity."
Malacological, Burlington House, W., 8 p.m. 1. Mr. E. A. Smith, "Description of a New Species of Acmæa from Bombay and Notes on Other Forms from that Locality." 2. Mr. H. B. Preston, "Description of Three New Species of Operculte Land Shells from Grand Cayman Islands." 3. Mr. G. K. Gude, "Further Note on Preoccupied Molluscan Generic Names and Proposed New Names."
Geologists' Association, University College, W.C., 8 p.m. 1. Dr. Carl Fred Kolderup, "The Geology of the District of the Bergen Arches." 2. Mr. Horace W. Monckton, "The Rock Formation of the Bergen District."

SATURDAY, JUNE 10...Royal Institution, Albemarle-street, W., 3 p.m. Dr. W. L. Courtney, "Types of Greek Women." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,055. VOL. LIX.

FRIDAY, JUNE 9, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

THE ROYAL SOCIETY OF ARTS.*

By Sir Henry Trueman Wood, M.A.,
Secretary of the Society.

I.—The Origin of the Society.

During the eighteenth century several societies were established in different parts of the three kingdoms for the encouragement of the Arts and Industries. The oldest of these is the Royal Society of Dublin. This was founded in 1731, under the title of the Dublin Society for Improving Husbandry, Manufactures and other Useful Arts. Previous to this, in 1683, a Philosophical Society, on the model of the Royal Society of London, had been formed. This had rather a chequered existence, and seems to have come to an end before the close of the seventeenth century. Later on the second Dublin Society was established, mainly by Dr. S. Madden, who himself provided prizes for useful inventions and for proficiency in the Fine Arts.

In 1749 this Society was incorporated under the name of the Royal Dublin Society, in which name it has ever since carried on much valuable work. It had the advantage of Government aid, and between 1761 and 1767 it distributed Government grants to the amount of £42,000 in the promotion of agriculture and manufactures.

* Nothing like a history of the Society has ever been written. A great deal of information is contained in a lengthy paper read in 1868 (see *Journal*, Vol. XVII. p. 10, etc.), by S. T Davenport, who was Financial Officer of the Society from 1853 till his death in 1875. The best account of the Society is to be found in a series of articles contributed to *Engineering* in July and August, 1891, by H. B. Wheatley (Assistant Secretary 1879 to 1909). A short but brightly-written sketch of the Society is given in "Scientific London" (B. H. Becker), 1874. The "Microcosm of London," published by R. Ackerman in 1811, gives a good account of the Society as it existed at that date, and contains an interesting picture of the Great Room, showing the arrangement of the room before the modern alterations. Charles Knight's "London," Vol. V. (1843) also contains an illustrated chapter on the Society. Some other accounts might be mentioned, but on the whole, outside of its own publications, the history of the Society must be sought in the magazines and newspapers of the last two centuries, from the *Gentleman's Magazine* and the *Public Advertiser* down to the periodicals and journals of our own time.

The London Society of Arts, therefore, dating as it does from 1754, though the oldest association of the sort in Great Britain, is younger by some twenty-three years than the sister society in Ireland.

Two other technical societies founded in the eighteenth century still survive, the Highland and Agricultural Society of Scotland (1784) and the Bath and West of England Agricultural Society (1774).

In America, before the foundation of the Society of Arts, Dr. Franklin had already published (1743) a "Proposal for Promoting Useful Knowledge Among the British Plantations," and this led to the formation of the American Philosophical Society, which still flourishes, but devotes itself exclusively to pure science. In 1765, after the establishment of the Society of Arts, a similar society was formed in New York, and a number of prizes were offered for industrial advances in the Province of New York. The first list of such prizes, which varied in amounts from £30 to £2, was sent to the London Society, and is still in existence. Many other societies, some of an industrial character, were started in America later, after the independence of the United States.

All the other technical societies established about this time had but a brief existence, and few of them have left any records behind them. Lecky* mentions a Society for Improving the Knowledge of Agriculture in Scotland as established in 1723. In 1754 there was founded the Select Society of Edinburgh for encouraging the Arts and Manufactures of Scotland. The principal promoter of this was Elizabeth, Duchess of Hamilton—one of the beautiful Miss Gunnings. Mrs. Palliser refers to this society in her history of lace, and mentions the award of prizes for Scottish lace for some few years. At one time this institution was in correspondence with the Society of Arts in London.

* "England in the Eighteenth Century," Vol. II., p. 318 (Edition 1909).

Perhaps the most curious of these institutions was the Anti-Gallican Society, which was established in London in 1750 or 1751, for the protection of native industries and the discouragement of French imports. This society seems, by reports which appeared from time to time in the *Gentleman's Magazine*, to have held quarterly meetings up to 1754, or thereabouts, at which meetings small prizes were awarded for English lace, needlework, etc. In 1753 a medal was presented to one Captain John Mead, "for having caught the greatest number of whales last season"; and another medal to Captain Cockburne "for his gallant behaviour to the commander of the French squadron at Annamobar, on the coast of Guinea." On another occasion they made a grant of five guineas to "an honest, industrious old couple" whose cow had died from "the distemper." For some time there is no further available information about their proceedings; but in 1759 they appear to have taken more strenuous action by starting the "Anti-Gallican" privateer. This ship captured a French Indiaman in Spanish waters, whence arose considerable difficulty; eventually the prize was declared illegal, and had to be given up. It looks as if this last effort in the promotion of British industries brought this Society to an end, for no further record of their proceedings appears.

There may have been other precursors of the Society of Arts, but research has failed to find evidence of their existence. After the Society was founded it had a certain number of imitators. The *Gentleman's Magazine* for 1755, p. 505, contains an account of a society established that year in Breconshire on the model of the Society of Arts, for the encouragement of local agriculture and manufactures by the offer of prizes, and the suggestion is put forward that other like societies might usefully be established in all the counties. After 1768, when, as hereafter mentioned, Shipley, the Society's founder, had retired to Maidstone, he founded a local society there which for some years did useful work.

Archdeacon Cunningham, in his well-known work,* mentions in his list of authorities "An Account of the Origin, Proceedings and Intentions of the Society for the Promotion of Industry in the Southern District of the parts of Lindsey in the county of Lincoln, 1789," but up to the present no further information about this institution has been discovered. A Society of Arts was established in Barbados in 1781, and continued to publish proceedings till 1784. These publications are mentioned in the supplement to Cundall's "Supplement to Biographia Jamaicensis," and copies are in the British Museum Library.

On the Continent the Society had at least one direct imitator, for it is recorded that the Empress Catharine II. of Russia was so much pleased with the account of the premiums offered by the Society of Arts, that in 1766 she established in her own dominions the Free Economical Society of St. Petersburg, with objects similar to those of the English Society.

Later on there were many societies founded, both at home and abroad, with similar objects to those of the Society of Arts, but all these were started after 1800. The closing years of the eighteenth century saw many more scientific, philosophical, and literary institutions founded, but none of these were of the same character as, or had similar aims or objects with, the Society of Arts.

The earliest proposal of which any record exists for the foundation of a Society of Arts in London goes as far back as 1721, when it is said that a pamphlet was published, entitled, "Three Letters concerning the forming of a Society to be called the Chamber of Arts, for the preserving of Operative Knowledge, Mechanical Arts, Inventions and Manufactures."* Probably the time of the South Sea Bubble was not a fortunate one for the exploitation of such schemes; certainly nothing came of the proposal.

In 1753 William Shipley † published in Northampton certain "proposals for raising by subscription a fund to be distributed in premiums for the promoting of improvements in the liberal arts and sciences, manufactures, etc." This was followed a little later in the same year by "a scheme for putting the proposals into execution," published in London.

* "English Industry and Commerce," Vol. II., p. 993 (Edition 1907).

* "Short Account of . . . the Society," etc., by a member (Edward Bridgen), 1765. A scarce pamphlet, giving an account of the Society of Arts' origin.

Another rather similar pamphlet, "A Concise Account . . . of the Society," was published two years earlier, in 1763. It also was anonymous, but was written by Thomas Mortimer. The information it contains is rather fuller.

† The materials for a life of Shipley are scanty. A certain amount of information is to be found in the Society's minute books and account books. The writer of the "Concise Account of the Society" previously referred to, states that an account of Shipley's proceedings in connection with the foundation of the Society was drawn up, and a copy presented to "the Antiquarian Society," by James Theobald, one of the Society's first Vice-Presidents. No such document, however, either in print or MS., is now to be found in the library of the Society of Antiquaries. The author of

Shipley was a portrait and landscape painter of no great merit. According to Redgrave* he was "better known as the founder of the St. Martin's Lane Academy, known as Shipley's School, where the best artists of a whole generation studied." Where Redgrave got his information from is unknown. No evidence can be found to prove that Shipley's Academy was in St. Martin's Lane, though the Academy founded by Sir William Thornhill in the Piazza, Covent Garden, was transferred there after his death by his son-in-law, Hogarth. Later on, in 1763, we find that special prizes were awarded by the Society to the pupils in this school, and also to the pupils of the school † established by the Duke of Richmond in Whitehall.

Shipley's Academy was certainly in the Strand. Where it was before Shipley's connection with the Society it does not seem possible to say. It must have been in existence, because Richard Cosway received his earliest instruction at it, and Cosway was amongst the first prize-winners of the Society. Afterwards it seems to have migrated with the Society to the various houses in which the offices of the Society were during the first five years of its existence—Craig's Court, 1755; Castle Court, 1756;‡ and Little Denmark Court, 1759. After this, when Shipley's official connection with the Society had ceased, there seems some reason to believe that his Academy was moved to the house at the corner of Beaufort Buildings (afterwards No. 96, Strand), which later on became Ackerman's Fine Art Repository, and later still Rimmel's well-known perfumery shop. Beaufort Buildings disappeared about 1902–4, when the new Savoy Hotel buildings were erected, and the Strand frontage was set back.

Not very much is really known about Shipley's life. He is said to have been born in London in 1714.* His father was Jonathan Shipley, "Citizen and Stationer" of London. He was a native of Leeds, who afterwards lived in Walbrook. William's mother was Martha Davies. Her family owned Twyford House, near Winchester, and the property was inherited by Shipley's brother Jonathan, the Bishop of St. Asaph. He was a liberal-minded divine, a friend of Franklin's; and it was said, probably without truth, that he might have been appointed Archbishop of Canterbury but for his strongly-expressed opposition to the American War.

William Shipley is said to have been originally a drawing-master in Northampton, and to have settled in London in 1750, though it was from Northampton that he dated his "Proposals." He appears to have been an active-minded man, full of ideas, and with some capacity for organisation; but perhaps devoid of ambition, for he never seems to have troubled himself to obtain either credit or profit out of the successful realisation of his ideas. According to a Maidstone tradition he was an absent-minded man, so much so, that on his way to church to be married he was led away by the sight of a rare butterfly to start on its pursuit and, consequently, arrived late for the ceremony. At all events, as soon as the Society he suggested was successfully established and flourishing, he retired from its concerns, though for some four years he seems to have devoted himself energetically and without much pecuniary reward to its establishment. For the first year after the Society was formed he acted as secretary without pay. When the Society was formally constituted in 1755 he was appointed secretary, and this post was afterwards, in 1757, changed to that of registrar.

In October, 1760, at a regular meeting of the Society, a letter from Shipley was read "acquainting the Society of his having lately engaged in business of such importance as to render him incapable of discharging his duty to the Society as their register without very much injuring

---

the "Concise Account," however, extracted a good deal from Theobald's narrative, and it is from this source that most of what we know about Shipley and his efforts to start a society are derived. A short life of Shipley is given in "Russell's History of Maidstone" (1881), and this gives some particulars of his later years. This information is reproduced in a short article in the *Journal* (Vol. XXX. p. 933), written by H. B. Wheatley. The account in the "Dictionary of National Biography" is based on this article, though other references are given. One or two mistakes appear in this account. Shipley was in all probability born in London, not in Maidstone, and he certainly died in Maidstone, and not in Manchester.

* "Dictionary of Artists of the English School."

† A note in the *Gentleman's Magazine*, March, 1758, p. 141, records the opening of this school. A room was supplied with busts and pictures for the use of art students. Wilton and Cipriani were engaged to attend at certain times and examine the students' work.

‡ "My late father, Nathaniel Smith, and Joseph Nollekens were playfellows, and both learned drawing together at Shipley's School, then kept in the Strand, at the eastern corner of Castle Court; the house, now No. 229, is at present occupied by Mr. Helps. What renders the building the more interesting is that it was not only in this house that the Society of Arts had its first meetings, but it was subsequently inhabited by Rawle, the antiquary, and friend of Captain Grose."—J. T. Smith, "Nollekens and His Times," 1828, Vol. I., p. 3.

* This is the date given in all the biographical dictionaries. The same year is given as the date of the birth of his brother Jonathan, and in his case correctly, as is shown by his monument in the churchyard at Twyford, near Winchester. The date on William's tombstone in All Saints' Churchyard, Maidstone, is illegible. Probably Jonathan was the elder brother. He inherited his mother's property at Twyford.

his own affairs." What this business was does not appear. It may have been the development of his academy. At all events, his resignation was accepted with thanks for his past services. That his retirement was not due to lack of appreciation of those services may be assumed from the fact that he was made a "perpetual member" of the Society in 1755, was presented with its gold medal in 1756, and had his portrait painted for the Society by Cosway, his former pupil. It may be that his capacity lay rather in the direction of origination than of administration. At all events, we hear no more of him in connection with the Society after 1760. In 1768 he went to live at Maidstone, where he was married, and remained until his death in 1803. He was buried in the churchyard of All Saints' Church. All that is known of his life at Maidstone is that he established a local Society on the same lines as the Society of Arts, and busied himself in philanthropic work.

Shipley, having published his scheme, set to work to secure the help of influential people, and succeeded in interesting, amongst others, Lord Folkestone and Lord Romney, to whom, with Shipley himself, must be given the credit of founding the Society of Arts. Indeed, it appears that if Shipley originated the idea, Lord Folkestone carried it into execution; and, in all probability, without his practical help and his influence there never would have been a Society of Arts.

On March 22nd, 1754, there was held at Rawthmell's Coffee House, Henrietta Street, Covent Garden,* "A meeting of some Noblemen, Clergy, Gentlemen and Merchants in order to form a Society for the Encouragement of Arts, Manufactures and Commerce in Great Britain." Eleven in all attended:—Viscount Folkestone;† Lord Romney;‡ Dr. Stephen Hales, F.R.S. (the eminent physiologist, botanist, and inventor, a friend of Pope); Henry Baker, F.R.S. (naturalist and author; he married Defoe's youngest daughter); Gustavus Brander, F.R.S. (merchant and antiquary, a director of the Bank of England); James Short, F.R.S. (optician and astronomer); John Goodchild (afterwards treasurer to the Society); Nicholas Crispe (watchmaker, of Bow Churchyard); Charles Lawrence; Husband Messiter (a surgeon, then resident in Great Pulteney Street); William Shipley.

A very modest beginning was made by considering a suggestion by Shipley that two prizes should be offered, one for the discovery of cobalt and the other for the growth of madder, in the kingdom. It was determined to make further inquiries and a decision was postponed. The meeting further resolved "to bestow premiums on a certain number of boys or girls under the age of sixteen who shall produce the best piece of drawing, and show themselves most capable when properly examined, "it being the opinion of all present that the Art of Drawing is absolutely necessary in many employments, trades, and manufactures." This early anticipation of views which in our own time were put forward as novel by the advocates of technical education is interesting. That they were really Shipley's ideas, and that his intention in proposing the formation of the Society was not merely to extend or improve his own "drawing academy" is shown by a letter written a couple of years later by him in the *Gentleman's Magazine*,* in which he combats vigorously the suggestion that the Society was merely occupied in training young people to become artists, and announces as one of the chief objects of the Society the training of both boys and girls in the industrial arts. Thus it can be truthfully said that from its first foundation the Society has taken an active part in the promotion of technical education.

A fortnight after the inaugural meeting a second meeting was held (March 29th), and at this further progress was made. A definite decision was arrived at to offer the cobalt and madder premiums, and a subscription list opened. Lords Folkestone and Romney headed the list with a donation of ten guineas apiece, and further promised to guarantee whatever further sums might be required, so that an announcement might be made of the offer of prizes. The Earl of Shaftesbury also sent ten guineas, and four others gave two guineas each. Funds being thus available, an advertisement was inserted in the *Daily Advertiser*, offering prizes of £30 each for specified amounts of cobalt and madder, and two prizes of £15 each for drawings by boys and girls below fourteen and between fourteen and seventeen. The competitive drawings were

* The precise locality of Rawthmell's Coffee House is described in an article in the *Journal*, Vol. LVIII., p. 384.

† Sir Jacob Des Bouveries (afterwards Bouverie) was created Viscount Folkestone in 1747. His father and grandfather were well-known Turkey merchants in London. His ancestor, Laurence des Bouveries, a native of Flanders, and a silk-weaver, settled in Canterbury in 1568, about the time when so many Flemish immigrants came to England to escape the persecutions of Alva. The title was merged in that of Radnor when the second Viscount Folkestone was created Earl of Radnor in 1765.

‡ Robert Lord Romney was the second Baron. He was a brother-in-law of Lord Folkestone, who had married his sister, the Hon. Elizabeth Marsham.

* January 28th, 1756, p. 61.

to be sent in on January 15th, 1755, and the prizes were to be awarded a fortnight later. Thus the practical work of the Society was begun.

Six more meetings were held during the year in a circulating library in Crane Court, Fleet Street, in which court was the house then occupied (from 1710 to 1780) by the Royal Society. These were all small meetings, of the nature really of committees, and at them the organisation of the Society was worked out, subjects for premiums discussed, and a general plan of action decided upon. Amongst other things it was decided to have a regular meeting on the second Wednesday in each month, and a committee on each fourth Wednesday.

By the end of the year all preliminaries seem to have been arranged, and it was decided to organise the Society on a more regular basis with a president and officers. This decision was arrived at at a meeting held in January, 1755, at Peele's Coffee House at the corner of Fetter Lane and Fleet Street.

At the same meeting the prizes offered for drawings were adjudged. The only name amongst those of the prize-winners which is still remembered is that of Richard Cosway, who took the first of the five prizes offered for drawings by young people under the age of fourteen. J. T. Smith, in his "Life of Nollekens," tells us that Cosway was then employed as a waiting lad at Shipley's Academy. He was afterwards a Royal Academician and an eminent portrait painter and miniaturist. John Smart, who took the second prize in the same class as Cosway, afterwards obtained considerable success as a painter of miniatures, and exhibited miniatures and oil portraits at the Royal Academy up to the time of his death in 1811. The third prize went to John Alexander Gresse, afterwards a painter of reputation, and the fourth to Barbara Marsden, who became a flower painter, and married Jeremiah Meyer, R.A. None of the candidates in the senior class appear to have achieved any artistic success in after life.

In the following month (February 5th) Viscount Folkestone was elected the first president, with Lord Romney, Charles Whitworth, James Theobald, and Stephen Hales, vice-presidents. John Goodchild was made treasurer, and William Shipley, secretary. At the same meeting Shipley and Henry Baker were elected "perpetual members." The Society was thus regularly constituted, and from that date forward meetings were regularly held for the election of new members and the transaction of business.

The title of the Society has always remained that which Shipley suggested in his original scheme, "The Society for the Encouragement of Arts, Manufactures, and Commerce," but this soon proved too long and cumbrous, and very soon after its foundation the shorter name, "Society of Arts," was adopted. In the *Gentleman's Magazine* of July, 1755, it is so called, and this soon became the name by which it was popularly known. Sometimes it is referred to as the "Society of Arts and Sciences," and in its own early books of accounts it is called "The Premium Society," though this title does not seem to appear elsewhere. The earliest known official use of the shorter name appears in the minutes in February, 1811, and from that time onwards it is constantly found. The full title was unfortunately adopted in the Charter in 1847, and the two names were used until King Edward VII., in 1908, granted the Society permission to add the word "Royal" to its title.

The constitution of the Society, at first and for very many years, was on a purely democratic basis. It had no governing body. There were certain standing committees and others appointed from time to time for special purposes, but their duty was merely to prepare the business for the general body of members, by whom all the business was transacted. The "ordinary meetings" were held first on alternate Wednesdays, and afterwards on every Wednesday from November to May, with less frequent meetings from May to November. The ordinary meetings were not competent to alter the "rules and orders." This could only be done at "general meetings," the number of which seems to have varied from time to time. At the ordinary meetings all the regular business of the Society was transacted, members were proposed, balloted for, and elected, bills were ordered for payment, and expenditure was discussed. Above all, subjects for the award of prizes were considered and voted upon.

It must be borne in mind that the sole object of the Society was to award premiums for meritorious discoveries and inventions, and for advances of any kind in arts, manufactures, and commerce. The meetings had before them descriptions of such advances, reports upon them, suggestions for new premiums, applications from inventors, but all these were merely intended to assist in the selection of suitable subjects for awards. The Society of Arts did not, like the Royal Society, welcome the description of new branches of knowledge (even of practical or applied knowledge); they

did not invite their members to contribute essays or read memoirs or give lectures—all that came later. They simply hoped to encourage industry and art by rewarding those who helped in the promotion of art and industry, and to give them either substantial money gifts, or honorary rewards in the nature of medals. Later, when the Society came to publish transactions, it received suitable information readily enough, gave the author a medal, and printed his communication. Eventually the publication became more important than the award, but this was not so at first, or for very many years after the Society's foundation.

It will be seen that the one idea of the founders of the Society was to encourage arts and industries by the offer of prizes. It appeared possible to them that a committee of gentlemen, sitting in London, would be able to ascertain what the pressing needs of the public were, to foresee the course which industrial development could most wisely take, to select those inventions which could most usefully be encouraged, and generally to direct, by the judicious apportionment of medals and money prizes, the development of industry and the progress of art. To us, nowadays, the whole scheme seems trivial and ridiculous, but at the time it was perfectly reasonable, and it commended itself to the shrewdest economists. As a matter of fact, it obtained a very considerable measure of success, and that it was extremely popular is shown by the support it received from the most influential people of the time.

An attempt has been made elsewhere* to indicate the industrial conditions of the era. Here it may suffice to remind the reader that the time was essentially one of industrial change. The old conditions of regulance and support had long since disappeared. The new conditions of competition and the absence of restriction were not yet conceived, let alone formulated. The various young industries, textile, metallurgical, chemical, ceramic and the rest, all wanted patronage and help. They wanted, too, advertisement and notoriety. All this they got from the newly-formed Society, and it may fairly be said that, having due regard to the then existing conditions, and to the state of public knowledge, it would be very difficult indeed to suggest any scheme better adapted for its purpose than that of Shipley and his patrons.

The annual subscription was fixed at "not less than" two guineas, and for a long time it was the practice of the more wealthy or more liberal members to pay three guineas. This excellent custom, however, has for many years been abandoned, though the wording of the old rule has been preserved. Peers were expected to pay five guineas, and for the most part did so. In a single instance, this practice survived into our own time. The late Marquis of Ripon (who was elected in 1856 and died in 1909) always subscribed five guineas annually. The composition for life membership was settled at twenty guineas, and has never been altered, though occasionally larger contributions were made. The great Earl of Bute, not by reputation a liberal or extravagant donor, gave forty pounds for his "perpetual membership."

The Society has never received any official aid. Less fortunate than the sister institution in Dublin, or than many of the great London societies which have taken over much of its original work, it has never been supported or helped in any way by Government. Lecky, in his "History of the Eighteenth Century," * says that it received a grant of £500 from the Corporation of London, but a careful search through the early account books has produced no confirmation of this statement.† In 1765 the Society received a donation of £100 from the Corporation of Liverpool, and this appears to have been the only contribution of the sort.

The Society was soon in a very satisfactory financial position. In 1755, the first year after its formal constitution, its income was £360. In the following year it was £632, and in 1757 it was £1,203. In the next six years it mounted steadily, £1,731 in 1758, £2,001 in 1759, £3,482 in 1760, £3,656 in 1761, £4,533 in 1762, £4,614 in 1763. Then, in 1764 there was a drop to £4,131.

At first all the Society's cash was in the hands of the treasurer, who was subject only to the control of a finance committee, which audited and reported on his accounts at intervals. The first treasurer was John Goodchild, one of the founders. He was elected in 1755, and held office until his death at the end of 1756, when he was succeeded by his son, also John. A year later we find a committee reporting on the treasurer's accounts "that the receipts and disbursements are right, but kept in rather a perplexed method." Probably the younger

* "Industrial England in the Middle of the Eighteenth Century." Murray, 1910.

* Vol. VII., p. 207 (Edition 1907).

† The books commence with 1755, the first entry being dated April of that year. If such a grant had been made in 1754 it could hardly have escaped notice in the minutes which record all the meetings, from the first at Rawthmell's onward.

Goodchild was a bad accountant, for in 1759 he was in difficulties and had to compound with his creditors, the Society in consequence suffering some small loss. The office of treasurer was thereupon declared vacant, and subsequently abolished. Careful regulations were then laid down as to finance, and it was ordered that all the Society's funds were to be kept in an account at the Bank of England in the names of the President and Vice-Presidents.

In an appendix to the premium list issued by the Society in 1764, there is a tabular statement of the "Receipts and Disbursements" for the nine years 1755 to 1763. The total receipts were £22,295, and the total expenditure was £18,756. Of this £8,496 was spent in money prizes and medals, £3,507 on a special grant for a system of land carriage for fish, £291 on the Society's exhibitions, and the balance of £6,462 on general administration, including rent, salaries, advertising, printing, etc. It is clear from this that the affairs of the Society were carefully and economically managed, for the cost of management as compared with the amount of the funds expended is very reasonable.

A later statement, issued in 1778 in the form of a "Register of the Premiums and Bounties given by the Society" up to the end of 1776, showed that the total amount given away by the Society was then £24,616, of which £23,552 had been money prizes, and £1,064 had been the value of the medals awarded. It may be noted that "premiums" were awards to "candidates who claim under the terms of the annual advertisements of the Society," and that "bounties" were "bestowed on merits that have not been previously called for by the Society, or that do not precisely come within the terms of the annual advertisements." It is added that "these amounts have been distributed all over Great Britain, Europe, and America"—a good general statement, which perhaps was not intended to be taken as minutely accurate.

As previously mentioned, during the first year of the Society's existence Shipley acted as secretary, at first unpaid. When the Society was formally organised in February, 1755, Shipley was appointed secretary. He appears to have had some clerical assistance provided for him, and in January, 1756, George Box was appointed assistant secretary. In March, 1757, Shipley was elected registrar, and Box was made secretary. The registrar was apparently the more important officer of the two, but the secretary did most of the work. It looks as if it had been desired to make his duties a little easier for Shipley, and to find somebody who was more methodical and businesslike to carry on all the routine business. Not very much is recorded of George Box, though it is evident that he was a most efficient and competent official. He served the Society faithfully for twenty-five years, and such records of him as appear from time to time in the minutes show that he was entirely trustworthy and possessed the regard and confidence of the members.

In 1760, soon after the Society, as will be hereafter related, had established itself in the house opposite Beaufort Buildings in the Strand, where it remained until it moved to the Adelphi, it was decided that a more competent and better-qualified secretary was required. A committee reported in February, 1760, that the proper conduct of the Society's work required a man of "general and technical knowledge," able to deal with scientific questions and conversant with foreign languages. "He ought to be a man of character and a man of learning," and such a man the committee thought might well deserve a salary of £200 a year. The general body of members approved the qualifications, but set a lower estimate on their value, and considered that the required person might be obtained for £150. The committee went on to recommend the appointment of an assistant secretary with a salary of £50 and a commission of 6*d*. in the pound on subscriptions, which at the time must have meant another £75 a year, so that the pay of the two officials was not very different. It is evident that the committee wished to do the best they could for Box, though they felt that he was not quite qualified for the more important post, since they add that they "take the liberty from the long experience of the diligence and integrity of your present secretary to recommend him to the office of assistant secretary and receiver." Later resolutions decided that the names of both officials were to appear in the Society's lists and other publications.

It was finally decided to appoint Box assistant, and to advertise for a secretary. As regards the office of registrar, the committee considered "the present register a very proper person to be continued in that office, and that he should do the business as usual"; that he should "have the salary and appartments now allowed him," and that he should be "allowed £10 a year more for taking care of the rooms, cleaning them and the furniture, and keeping all things in proper order for the reception of the Society."

This looks as if the Society desired to provide a home and an easy post for Shipley without expecting from him very much useful work.

In response to the advertisement four candidates applied—Dr. Templeman, Dr. Maty, Dr. Mitchell and Mr. Robert Dossie. It has often been said that Oliver Goldsmith was a candidate, but, as a matter of fact, though he thought of sending in his name, and applied to Garrick for a testimonial, he never actually went so far as to make formal application. The authority for the statement is Thomas Davies, who, in his "Life of Garrick,"* tells us that Goldsmith asked Garrick to recommend him, but that Garrick had been annoyed by Goldsmith's criticisms, and rather curtly refused. Forster, in his "Life of Goldsmith," adopted Davies's story:—

"Thomas Davies tells us that when, somewhere about the time of his connection with the *Bee*, Goldsmith sought to obtain, what a struggling man of letters was thought to have some claim to, the vacant secretaryship of the Society of Arts, Garrick made answer to a personal application for his vote, that Mr. Goldsmith, having 'taken pains to deprive himself of his assistance by an unprovoked attack upon his management of the theatre in his "Present State of Learning,"' it was 'impossible he could lay claim to any recommendation from him.'" †

The compiler of this chronicle would like to think that Oliver Goldsmith had been an occupant of the post he now holds, though he realises that the talents of that charming writer were better employed in producing the "Vicar of Wakefield," "She Stoops to Conquer," and "The Deserted Village," than in discharging the routine duties of an office which no doubt was better filled by the successful competitor, Dr. Templeman. Still, the name of Goldsmith on the list of the Society's officials would have added not a little distinction to that list, even if, as would probably have been the case, he had not held an uncongenial office for very long.

Of the four candidates who actually did enter, Templeman was elected by a considerable majority. Box was appointed assistant secretary, in accordance with the recommendation of the committee. Later in the year Shipley, as previously mentioned, resigned his office of registrar, perhaps not liking the new conditions, or perhaps, as he said, on account of his other occupations.

Templeman was a man thoroughly well qualified for the post of secretary to a young and growing society. He had a distinguished career at Cambridge, where he graduated from Trinity in 1731. He studied medicine in Germany, and in 1737 he obtained the degree of M.D. at the University of Leyden. After this he started practice in London, but being fairly well off he devoted himself to literature rather than to the practice of his profession. In 1758 he was appointed Keeper of the Reading Room at the newly-established British Museum, and he gave up this post for the secretaryship of the Society. He was the author of numerous medical books, and in 1762 he was elected a Corresponding Member of the Royal Academy of Science of Paris. He was a fine scholar, a good linguist, and an accomplished man, well fitted for the post to which he was elected, and which he held until his death in 1769.

The duties of the three principal officers were laid down with great precision in the Society's "Rules and Orders." The secretary was generally responsible for the proper conduct of the Society's business and the due keeping of its records. The assistant secretary had to do all the clerical work, and the registrar had charge of the Society's property, and was required to look after the premises. In addition, there was a collector, who had to collect subscriptions and to pay them into the bank. He was paid by commission and had to give security.

(*To be continued.*)

SUDAN EXPORTS.

When the Central Economic Board of the Sudan Government came into being a few years ago, the value of the exports from the Sudan was estimated at about £E264,000, a very small sum when it is remembered that the territory extends for 950,000 square miles. To deal with such a limited amount may seem, at first sight, an easy matter. At the same time there has been no little difficulty in selecting a general policy, especially as the trade is passing through a transitional period. Experience shows that it is better, for the time being, to depend on the familiar conditions known to the native than to endeavour to induce him to adopt means of livelihood with which he is not acquainted.

The making of the railway to Port Sudan, and the improvement of trade routes, have shown that, under the prevailing circumstances, rain-grown products are of more importance, economically, than cultivation by mechanical means north of Khartoum.

Private capital is required to develop cotton cultivation in Northern Sudan. As this is not forthcoming, it is found best to devote all funds available to extending railways and instituting

* Vol. II., p. 149.

† Forster's "Life of Goldsmith," Vol. I., p. 239.

nucleus trading depots. The transport question is being rapidly disposed of, but agricultural problems in the Southern Sudan have not yet been tackled. The development of the cattle trade depends on the scientific skill which can be applied to the prevention of animal diseases. There are, at present, not sufficient funds to take this matter fully in hand.

It is only a very few years since the exports of the Sudan might be roughly summed up as gum, ivory, and ostrich feathers. The list of Sudan exports now includes live-stock, hides and skins, rubber, beeswax, mother-of-pearl shell, wheat, millet, barley, cotton and cotton-seed, sesame, ground nuts, dates, senna, and gold. The value of exports, which in 1906 stood at £E264,096, is now £E673,902. Some 80 per cent. of the exports of 1909 were rain and flood products. In view of the development of the food products of the Sudan, it is hoped, before very long, that the country may furnish a very large proportion of the food supply of Egypt, and may also help to solve the labour difficulty by drawing agriculturists to the Sudan.

The extension of the Sudan trade to external markets will necessitate transport and co-operation between the Government and the public. The Sudan Chamber of Commerce has already reduced rates on dura (millet) from Port Sudan to Suez and elsewhere. The Government have been glad to make use of its services in putting foreign correspondents in touch with local merchants.

For a considerable time agricultural loans have been in force in the Sudan. These are now to be extended to the purchasing of selected cotton seed for the Tokar district of Red Sea Province. If this should result in the quality of the cotton grown in that district being raised to the Egyptian standard, it would be a good argument for the institution, by joint Government and public contribution, of ginning and pressing machinery sufficient to deal with the crop, and so make possible the direct export of cotton from Port Sudan to Europe.

For some time the technical department of the Gordon College has been ginning cotton for the public at Khartoum and in Kassala.

At Port Sudan the completion of the quays has permitted the substitution of mechanical for manual handling, and bonded warehouses are to be instituted at Khartoum and Port Sudan.

The construction of the Blue Nile Railway will bring crops on to the market at the same time as those from the White Nile and Kordofan districts. Although the White Nile is open to traffic all the year round, the Blue Nile is not navigable for quite six months in the year. With the exception of products borne on the backs of camels, Blue Nile products have hitherto reached Khartoum market some months later than those from the White Nile. If the crops could arrive simultaneously, it would steady the price of certain commodities, such as sesame and dura. Now, if dura would maintain a fairly low price in the Sudan, it is quite possible that there would be a steady annual export to Egypt. There is also no reason why the Sudan should not provide all the sesame needed in Egypt. The railway will be of great service to the cattle-producing areas in the Sudan, and will bring the Abyssinian frontier into closer touch, although, up till now, the efforts to extend trade in Abyssinia have not been very successful.

Part of the programme of the Economic Board has been to substitute production in the Sudan for imports from abroad. A table published in 1907 showed that imports of certain commodities amounted to £E237,000. These articles are wheat, maize, barley, rice, flour, dates, sugar, timber, and salt. It will take some time to carry the policy into effect, but the basis is being laid. The chief export is gum. The crop of 1909 is the largest recorded, and reached 13,282 tons. The new railway between El Obeid and the White Nile will produce a complete change in the conditions of transport. It is likely that the extension of the line along the White Nile will help to develop the gum trade in the districts along the river. The Governor at Khartoum is attempting to put an end to some of the abuses in connection with the porterage and weighing of gum at Khartoum. The export of dura developed more than any other commodity last year. Dura is easily grown. It remains to be seen whether the big crops will continue steadily, or whether the natives will be industrious by fits and starts. The large export of dura during the last two years has been due to the reduction of the railway rates at a time of scarcity. Egyptian merchants were quick to take advantage. Sudan dura was exported in such quantities that private transport could not cope with it, and Government had to lend assistance. The question of how to maintain the big crop is being dealt with. The desirability of developing traffic between Port Sudan and Suakin has been put before the Khedivial Mail Steamship Company.

Oil seeds form a considerable item of the Sudan exports. The most important of these is sesame. It has already been put on European markets with profit, and sesame and sesame oil are in large demand amongst the native population.

Ground nuts have been cultivated on some estates, under European management, to the north of Khartoum. The rain districts to the south of Khartoum should also offer a good field in course of time.

Experiments made in the growing of castor seed show that it can be cultivated in certain districts with good results.

The unreliability of the water-supply in the Tokar district has caused a less area to be put under cotton cultivation during the last two years, and so there has been a decrease in the total exports of ginned cotton. In spite of the uncertainty of the water-supply, the Tokar cotton is of great value to the country. The Government are at present occupied with the question of providing good seed, the native cultivator not being sufficiently particular in this respect.

The Sudan possesses very large supplies of cattle, sheep, and goats, and these should form a large

and permanent export to Egypt, now that the principal veterinary officer has prepared a scheme by which the live-stock can be moved to Egypt under veterinary supervision.

Nearly the whole of the date crop gōes to Egypt. Unfortunately, the owners cannot or will not wait until their dates are ripe before selling, so they lose part of the profits.

The following table gives the value of the chief Sudan exports for the year 1909, in Egyptian pounds:—

Gum	£E371,896
Dura	136,599
Sesame	63,066
Ground Nuts	3,594
Ginned Cotton	39,283
Sheep and Goats	39,395
Ivory	45,056
Dates	35,306

ARTS AND CRAFTS.

Home Arts and Industries.—The difference between the way in which home arts and industries used to be regarded some twenty years ago, and the point of view from which we look upon them now, is very clearly shown by the change which has, little by little, come over the annual exhibition of the Home Arts and Industries Association. This used at one time to consist almost entirely of the work done in winter evenings in village and town classes, or by married women and girls in the country in their spare time. To-day, though a very fair proportion of the work comes from sources such as these, they can hardly be said to provide the bulk of the exhibits, still less to supply them exclusively. A number of the stalls at the Albert Hall this year were given over to "Affiliated Societies," described in the programme as "classes and industries that are held in connection with any Society, Institution, Guild, or Home"—which include several agencies for the employment of the blind, crippled, and feeble-minded—whilst many others were devoted to "developed," or "partially-developed industries," explained, in their turn, as industries that are wholly or partly self-supporting, with full-time or part-time workers, and either a paid management and depôt or receiving voluntary help in management or loans of capital. Thus the work shown under the auspices of the Association at the present time varies from the modest output of the village class to what is really handwork produced more or less in the way of trade—sometimes so completely trade as to make one wonder how the industry comes to be represented at a semi-philanthropic exhibition like the Home Arts, sometimes charitable to such an extent that one feels it is really only the courtesy and good feeling of the classholder which cause it to be labelled as anything but an ordinary class. From one point, of view, of course, the exhibition suffers rather from this mixture in the types of workmanship represented. In most industries the work of the man who does his handwork more or less as a recreation will not, of course, bear comparison with that of one who is earning his living at it. Moreover, the show is not so much of a homogeneous whole as it used to be. On the other hand, the mere fact that classes and associations of such utterly different types are represented is perhaps one of the strongest imaginable proofs both of the strength of the movement at the present time and of the work that it has done in the past. When the Association was first started, work executed by classes whose workers were supporting themselves by their handiwork was not exhibited, for the excellent reason that it practically did not exist—and the fact that such work is so plentiful as it is at the present day is due, at any rate, in some measure to the efforts of the Home Arts and Industries Association. The crafts most fully represented this year were embroidery, lacemaking, and woodcarving. The cutwork from Langdale was, as usual, exceedingly good, and there were interesting exhibits from Windermere, Wilton and the Dune Emer Guild. The coarse couched crewel work from the last-named class (executed, by the way, in the hand) was really peculiarly effective. Some of the lace was very well made, though the designs were not always all that could be desired. There seems to be a tendency to make more Honiton lace than formerly outside the limits of the county of Devon. Many of the weaving exhibits were characterised by the pleasant colour of the materials; and the simple but effective pattern-weaving shown by the Barclay workshops for the blind was very tasteful. Inlay work, after a period of depression, is well to the front again this year, and some of the leather-work classes sent important exhibits. There was an attractive show of work executed in Niger leather from Leighton Buzzard, and this exhibit included some lacquered leather much less hard and glaring in colour than the work of this kind which has been shown before.

Simple Homes and Furniture.—The House and Home Exhibition at the Whitechapel Art Gallery has much to connect it with the Home Arts and Industries. One of the aims of the show is to demonstrate the futility of fussiness in furniture and decoration, and the advantages of simplicity, with the result that the furniture and fittings exhibited are, for the most part, hand-made. Mr. Ernest Gimson, the Artificers' Guild, and others, sent plenty of good workmanship in wood and metal, whilst the coarse appliqué embroidery lent by the Peasant Arts Society is much of it very effective. The exhibition as a whole does a very needful bit of work in insisting upon the beauty of simple furniture and the superfluity, as well as the ugliness, of much that is taken to be essential in a modern home of even the most modest proportions. But there is a certain amount of affectation of simplicity in some of the exhibits which, apart from being undesirable in itself, will probably hinder the usefulness of the object-lesson to

the very people to whom it is particularly meant to appeal—quite apart from the consideration that the price of these things, simple as they are, would in many cases be quite prohibitive to all but the more than ordinarily well-to-do. Again, the people who are especially and pre-eminently lovers of fresh air and country cottages, seem to find it very difficult to realise that furniture which is admirably adapted for rural districts may be, and often is, quite unsuitable and out of place in a town dwelling. The two little bays described as "Two Stepney Rooms" are really, in spite of one or two unnecessarily ugly touches, the part of the collection which may be expected to appeal most strongly to the people who live in the neighbourhood of the Whitechapel Art Gallery—for they are eminently practical, and even though one might like, personally, to alter one or two things in them, they do represent a way of furnishing a working-man's home which is pleasanter than the arrangements one habitually sees, without being appreciably more expensive. The usefulness of this section would be considerably increased if a list of the prices of the various objects were hung up near by. The pottery shown needs just one word of comment. Some good pieces of a comparatively expensive kind of ware are shown by Messrs. Pilkington and Messrs. Martin, but the ordinary crockery arranged on the dressers, etc., is uglier and commoner looking than that which one usually sees in a working-class home. It is, of course, easy to find fault with details, but the promoters of the exhibition now open at Whitechapel are to be congratulated, both on the happy thought which inspired their exhibition for this year, and on the skill and thoroughness with which they have carried it out.

The Guild of Embroideresses.—Exhibitions of embroidery are apt to be rather in the nature of glorified bazaars, or to be held under the patronage of so many noble patrons that one begins to wonder whether the embroideresses themselves have any interest in them beyond the purely commercial one of selling their work. The little show held at the Modern Gallery towards the end of May, by the Guild of Embroideresses, marked a real effort in a healthier and a better direction. The patrons of the guild, amongst whom may be mentioned Sir Alfred East and Mr. Walter Crane, are all artists of repute, and its members consist of needlewomen, both professional and amateur, who are really interested in embroidery, practical, theoretical, and historic, for its own sake. The exhibition, which was opened by the Slade Professor of Fine Art at Oxford, Mr. Selwyn Image, though small, embraced a variety of kinds of work, and was by no means devoted to showing stitchery or design of any one particular type. Perhaps the most striking exhibits were a curtain and a cushion worked by Mrs. Newberry from old Macedonian designs, which, both in their colouring and stitchery, were all that could be desired. Miss Louisa F. Pesel's rendering in embroidery of designs from plaster work at San Sophia and from an Oriental MS. were also most satisfactory pieces of workmanship and of colour. In a very different way, the large appliqué figure panels by Miss Ethel Higgins, boldly executed in rose-red velvet on a neutral-coloured ground, were a model of what work of that particular type should be. The most wonderful piece of fine needlework was a little Japanese scene worked by Miss Sealy in white thread on fine white muslin. Its execution must have involved an almost incredible amount of labour, but as a *tour-de-force* it was very well worth doing. Miss Janet Swindells showed some beautiful satin stitch, Miss Tann several very tasteful colour-schemes, and Miss Pryce an excellent gold sampler. Taken as a whole, the exhibition sent one away with the feeling that, however much the work in London and one or two of the large provincial towns may be inclined to move in one rather narrow groove, there are still plenty of competent workers who look at their craft from a wider point of view. While this is the case, there is always a reasonable hope that things will, in the long run, right themselves.

CORRESPONDENCE.

IMPROVEMENTS IN THE TRANSPORT AND DISTRIBUTION OF GOODS IN LONDON.

I have received the enclosed letter from a friend who has great experience and wide knowledge with regard to the transportation of parcels and goods in London, and I think it will be of interest to those who have followed the correspondence which has arisen on the subject of my recent paper to members of your Society.

A. W. GATTIE.

[*Enclosure.*]

I have been much interested in the matter contained in recent issues of the *Journal* about the proposed Clearing House for Goods, and have noticed especially a letter signed "S. Chapman," in which the writer says:—

"It may be taken for granted that the bulk of orders coming by post arrive by the early morning deliveries. These orders are dealt with in the course of the day, and are ready towards evening for collection in order to be sent to various parts."

I am in entire disagreement with this statement. I maintain that the one reason why the packages for luggage rail are not ready till towards evening is because there is no system of collection by the railway companies earlier in the day, and in consequence the goods have to be held over, often at serious inconvenience to the traders who have none too much room in their warehouses.

It may interest your traders to know that nine-tenths of the big City and West-End houses collect

the morning's mail by special messengers from the district post-office. Such people as Cook, Morley, Rylands, Howell, Sharp Perrin, Foster Porter, etc., in the City, and Whiteley, Harrod, Selfridge, Schoolbred, Maple, etc., in the West-End, have their letters in the house by 6.30 a.m., and in many cases special orders are dealt with and out for delivery in their own vans by 8 o'clock, and frequently the orders are put in hand at once and dispatched as early as possible throughout the entire day.

Sutton & Co. close their gates at 4 p.m. sharp (Saturdays 1 p.m.), yet the railway companies are receiving hours after this, and, although they profess to close at 6.30, many vans enter the goods yards after 8 o'clock.

There are hundreds of City firms who would welcome an early dispatch, but who now put off the packing of package for goods trains till after 4 p.m., otherwise the packages are in their way.

I am convinced that the Clearing House will remedy this present unsatisfactory state of things, and am prepared to give it a hearty welcome.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 12...Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Chemical Industry (London Section), Burlington House, W., 8 p.m. Mr. H. de Mosenthal, "Observations on Cotton and Nitrated Cotton."

Geographical, Burlington-gardens, W., 8.30 p.m. Dr. Arthur Neve, "Some Explorations in the Himalayas."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. E. Richmond, "Egyptian Architecture."

Actuaries, Staples Inn Hall, Holborn, W.C., 5 p.m. Annual Meeting.

Victoria Institute, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Rev. W. St. Clair Tisdall, "Mithraism: Christianity's Greatest Rival under the Roman Emperors."

TUESDAY, JUNE 13...Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. A. B. Keith, "The Vedic Ākhyāna and the Indian Drama."

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Statistical, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. Sir J. Athelstane Baines, "Under the Crown."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. E. Sanger Shepherd, "On the Cause of Reversal and its Remedy, with Some Notes on the Photographic Process."

Zoological, Regent's-park, N.W., 8.30 p.m. 1. Dr. R. E. Drake-Brockman, "On Antelopes of the Genera *Madoqua* and *Rhynchotragus* from Somaliland." 2. Hon. Paul A. Methuen, "On an Amphipod from the Transvaal." 3. Mr. R. Lydekker, "The Somali Rhinoceros and the Nigerian Klipspringer." 4. Mr. C. E. Hellmayr, "A Contribution to the Ornithology of Western Columbia." 5. Professor Angel Cabrera, "The Subspecies of the Spanish Ibex."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Address by Sir Joseph Ward, Prime Minister of New Zealand.

Faraday Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Professor Ernst Cohen (of Utrecht), "Allotropic Forms of Metals."

Gas Engineers, Glasgow and West of Scotland Technical College, Montrose-street, Glasgow, 10 a.m. Annual General Meeting. 1. Address by the President. 2. Report of the Carbonisation Committee. 3. Third Report of Gas Heating Research Committee. 4. Report of the Refractory Materials Research Committee. Selections from following papers:—5. Mr. C. F. Broadhead, "Modernising a Medium-sized Undertaking." 6. Mr. Bernard F. Browne, "Aspects of Gas Supply in a South American City." 7. Mr. Charles Drury, "The Dessau Vertical Retorts at Sunderland." 8. Mr. P. C. Holmes Hunt, "The Choice of a Carbonising System." 9. Mr. S. B. Langlands, "Public Lighting." 10. Mr. J. P. Leather, "The Woodall-Duckham System of Vertical Retorts." 11. Mr. James McLeod, "Notes on the Corrosion of Service Pipes." 12. Mr. J. G. Newbigging, "The Scientific Carbonisation of Coal." 13. Mr. E. W. Smith, "The Uses of High-pressure Gas for Industrial Heating Purposes." 8 p.m. Professor W. A. Bone, "Surface Combustion."

WEDNESDAY, JUNE 14...Meteorological, 70, Victoria-street, S.W., 4.30 p.m. 1. Dr. Charles Chree, "The Diurnal Inequality of Barometric Pressure at Castle O'er, Dumfriesshire." 2. Mr. Spencer C. Russell, "Rain Drop Experiments." 3. Mr. A. J. Makower, Dr. W. Makower, and Messrs. W. M. Gregory and H. Robinson, "Investigation of the Electrical State of the Upper Atmosphere, August, 1910."

Geological, Burlington House, W., 8 p.m. 1. Professor W. S. Boulton, "On a Monchiquite Intrusion in the Old Red Sandstone of Monmouthshire." 2. Mr. F. G. Collins, "Notes on the Culm of South Devon: Part I., Exeter District"; with a Report on the Plant-Remains, by Mr. E. A. Newell Arber, and Notes on the Cephalopoda, by Mr. G. C. Crick.

Chemical, Burlington House, W., 8 p.m. (Faraday Lecture.) Professor T. W. Richards, "The Fundamental Properties of the Elements."

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. G. C Druce, "Notes on the Heraldic Jall or Yale."

East India Association, Caxton Hall, Westminster, S.W., 4 p.m. Sir James Wilson, "Indian Currency Policy."

Gas Engineers, Glasgow and West of Scotland Technical College, Montrose-street, Glasgow, 10 a.m. Annual General Meeting continued.

THURSDAY, JUNE 15...Geographical, Savile-row, W., 5 p.m. (Research Meeting.) Dr. A. Strahan, "Report on River Investigation."

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Miss H. M. Cunnington, "The Anatomy of *Enhalus acoroides*, Rich." 2. Professor A. D. Imms, "On the Life-history of *Croce filipennis*, Westw." 3. Professor J. J. Kieffer, (*a*) "Cynipidæ," (*b*) "Proctotrupoidea." 4. Professor T. D. A. Cockerell, "Apoidea." 5. Mr. J. C. F. Fryer, "Lepidoptera." 6. Mr. G. Meade-Waldo, "Wasps." 7. Mr. J. E. Collin, (*a*) "Borboridæ," (*b*) "Phoridæ." 8. Mr. F. V. Theobald, "Culicidæ." (Papers 3-8, relating to the fauna of the Seychelles, are communicated by Professor J. Stanley Gardiner.)

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. A. G. Vernon Harcourt and H. B. Baker, "The Alleged Complexity of Tellurium." 2. Messrs. W. R. Bousfield and T. M. Lowry, "The Purification and Properties of Acetic Acid." 3. Mr. S. U. Pickering, "Cupriglycollates."

Gas Engineers, Glasgow and West of Scotland Technical College, Montrose-street, Glasgow, 10 a.m. Annual General Meeting continued.

Journal of the Royal Society of Arts.

FRIDAY, JUNE 16, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Fifty-Seventh Annual General Meeting, for the purpose of receiving the Council's report and the Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held, in accordance with the By-laws, on Wednesday, June 28th, at 4 p.m.

(By order of the Council),

HENRY TRUEMAN WOOD, *Secretary.*

SOCIETY'S ALBERT MEDAL.

The Albert Medal of the Society for the current year has been awarded by the Council, with the approval of His Royal Highness the President, to the Hon. Charles A. Parsons, C.B., LL.D., D.Sc., F.R.S., for his experimental researches into the laws governing the efficient action of steam in engines of the turbine type; and for his invention of the re-action type of steam turbine and its practical applications to the generation of electricity, the ventilation of mines, blast-furnace work, ship propulsion, and other important purposes.

The beneficial results which have followed upon these inventions include a cheapening of the production of mechanical power, greater economy and speed for steamships, and the first successful solution of the problem of rotary engines which long had baffled many other inventors.

PRIZE FOR LIFE-SAVING APPARATUS FOR USE IN NOXIOUS ATMOSPHERES.

At their meeting on Monday, the 12th inst., the Council had before them the following report of the Committee appointed to consider the applications for the above prize. They decided to approve the recommendations of the Committee, and to award medals in accordance with those recommendations, viz.:—

A gold medal to Mr. H. A. Fleuss, for the apparatus submitted by Messrs. Siebe, Gorman & Co.

A gold medal to Mr. W. E. Garforth, in recognition of his efforts to perfect and to secure the adoption of rescue apparatus in mines.

A silver medal for the "Draeger" apparatus submitted by Mr. Richard Jacobson.

A silver medal for the "Meco" apparatus submitted by the Mining Engineering Company.

REPORT OF COMMITTEE.

In the year 1907 the Council decided to offer, under the Fothergill Trust, a gold medal, or a prize of £20, for the best portable apparatus or appliance for enabling men to undertake rescue work in mines or other places where the air is noxious, the object being to encourage the production of a rescue apparatus which would enable a succouring party to reach men cut off —in case of mining accidents—by irrespirable gases, or overcome by them. It was known that many such appliances existed, but it appeared uncertain which of them were the best, or even which were of practical use.

In response to the offer a number of appliances were submitted by the specified date (March, 1908), and the Council appointed a committee to deal with them. It was intended that all the apparatus sent in should be submitted to practical trials, and it was hoped that this might be done and the award made without any very great delay. It turned out, however, that facilities for the purpose were unfortunately not immediately available, and, consequently, the proposed trials had to be postponed.

At the end of 1909 the Council were informed that facilities for carrying out tests would shortly be at their disposal, but so long

a time had elapsed since the original offer that some inventors who had notified their intention of competing had already made considerable alterations and improvements in their apparatus, and applications had also been received from other inventors, whom the Council would have been reluctant to exclude from the competition. After careful consideration of the circumstances, and having regard to the fact that the right was reserved of extending the time, the Council decided to cancel the original offer and to accept for competition any apparatus which might be submitted not later than March 31st, 1910.

The committee have carefully considered the various types of apparatus submitted to them, and they have had the advantage of also considering the results of the trials that have been made at various experimental stations, including the valuable and exhaustive series of trials recently made at Birmingham.

Since the proposal for a prize was put forward, many modifications have been made in the apparatus, and these also have been considered.

By the appointed date the following apparatus were submitted :—

1. The "Draeger" compressed-oxygen apparatus, by Richard Jacobson, 70, Shoe-lane, E.C., British Agent of The Draegerwerk (Heinr. and Bernh. Draeger), Lübeck.
2. The "Aerolith" liquid-air apparatus, by Henry Simonis & Co., Pretoria Works, Walthamstow, E.
3. The "Meco" compressed-oxygen apparatus by the Mining Engineering Co., Ltd., Foster's Buildings, High-street, Sheffield.
4. The "Weg" compressed-oxygen apparatus, with automatic supply, by W. E. Garforth, M.Inst.C.E., Snydale Hall, Pontefract.
5. Siebe, Gorman & Co.'s Fleuss compressed-oxygen apparatus (embodying improvements by Mr. H. A. Fleuss, Dr. Leonard Hill, F.R.S., and Mr. R. H. Davis), by Siebe, Gorman & Co., Ltd., 187, Westminster-bridge-road, S.E.
6. Apparatus for submarine work, using oxygen generated from a material termed "oxylith," by Captain S. S. Hall, R.N., H.M.S. "Mercury."

In addition to these there were two apparatus which were sent in late, and certain less important devices, which were eliminated by the committee after a preliminary examination.

It will be noted that of the above apparatus four depend on the supply of compressed oxygen, one on the provision of air evaporated from liquid air, and one—that of Captain Hall and Staff-Surgeon Rees, sent in by the first-named—on the production of oxygen from "oxylith." With regard to the last-named apparatus, there seems no doubt that though it is extremely well adapted for the purpose for which it was constructed—for use in submarines—it is not at present adequate for use in mines, except, perhaps, for short and easy pieces of work, where its lightness and simplicity might be advantageous. With regard to the apparatus of the other five competitors, the committee are satisfied that any one of them might be of the utmost value for use in mine accidents, where access to the workings was prevented by their being filled with irrespirable gases. They would be valuable alike for the rescue of human life, and also for carrying on such operations as might be required; for instance, the construction of a wall to cut off part of a mine which was on fire, or the closing of a door to alter the direction of the air-current.

It must be borne in mind that the use of any apparatus of this sort must of necessity be limited by various considerations. The apparatus requires to be known by the person using it, and it can only be usefully employed by a man having a certain amount of experience in its use and a certain amount of practical skill. The distance to which the wearer can travel is also limited. There is no doubt that the physical exertion involved in making one's way through passages of a mine, probably blocked up by the fall of *débris* and other obstacles, in almost entire darkness, and under conditions involving very great mental strain, must of necessity be very considerable.

The five apparatus considered all vary in construction; each of them possesses details in which it is superior to the rest. It is probable that in the future some apparatus may be constructed embodying the advantageous points of all of them, and avoiding the defects. The principal points of difference, apart from the fundamental principles on which the apparatus are constructed, appear in the comparative lightness and convenience of carriage, and in the arrangements for enabling the wearer to breathe either by the use of a helmet, or by means of mouthpieces of various construction.

The committee do not consider that the liquid-

air apparatus sent in is as yet sufficiently perfect to justify its adoption in preference to the older systems, under which oxygen is supplied from a receptacle containing the gas in a state of compression. Liquid air, although, perhaps, it can in the future be obtained in sufficient quantities, and with sufficient readiness, is not easy to store; and it is probably hardly possible to avoid very great waste. Other points are the extreme cold produced by its evaporation, and the difficulty of properly regulating this evaporation. But the apparatus is one of the highest interest, and it is to be hoped that its development will be continued.

The committee have found a difficulty in reaching the conclusion that any of the other four apparatus is so far superior to the rest as to justify the award of the prize to it, and it alone.

They are, however, of opinion that the apparatus originally invented by Mr. Henry A. Fleuss, and submitted in its improved condition by Messrs. Siebe, Gorman & Co., Ltd., has sufficient points of superiority to justify an award to its inventor. They, therefore, recommend the award of a gold medal to Mr. Henry A. Fleuss, who as long ago as 1883 received a gold medal from the Society of Arts, under the Shaw Trust, for this apparatus in its original form. The fact that Mr. Fleuss was certainly one of the first to propose, and the first to bring into practical form, an apparatus of this type, has had very great weight in the decision at which the committee have arrived.

They also wish to recommend to the Council that they should award a second gold medal to Mr. William Edward Garforth, in recognition of his long-continued and public-spirited endeavours to perfect and to secure the adoption in this country of rescue apparatus in mines, and also as an acknowledgment of the merits of the principles which he has applied to the apparatus he has himself devised, but which are equally applicable to all similar forms of rescue apparatus.

In addition to these two gold medals, the committee recommend to the Council the award of a silver medal for the Draeger apparatus submitted by Mr. Jacobson, and for the Meco apparatus submitted by the Mining Engineering Company of Sheffield.

They believe that any of the four apparatus would be efficient, each of them having its own points of merit; and, as before observed, the perfect apparatus, if it is ever constructed, will probably include features derived from all of them.

THE ROYAL SOCIETY OF ARTS.

By Sir Henry Trueman Wood, M.A.,
Secretary of the Society.

II.—The Earliest Lists of Members.

It was some little time before the ideas started by Shipley and his patrons really got hold of the public. At first no special efforts seem to have been made to obtain subscriptions and attract public support. From the date of the first meeting till the constitution of the Society, nearly a year later, only seventeen members were enlisted. In the first two months after the election of officers in February, 1755, the number was raised to eighty-one, and after that the increase was fairly rapid.

The most interesting record of these early days is an ancient signature-book, which, according to its titlepage, was a "List of the Nobility, Clergy, Gentry, Merchants, etc., who have subscribed towards raising a Fund for the Encouragement of Arts, Manufactures, and Commerce, 1754." The signatories of the book bound themselves by the undertaking: "We promise to pay annually during pleasure the several sums to which our names are respectively prefixed."

This seems to have been the original form of the list of members, and as it contains the autographs of a very large proportion of the distinguished persons who from the first supported the young Society, it is really a document of very great value, even though a considerable proportion of the members never signed it at all. Some of the more interesting signatures have been reproduced in facsimile, and a selection from these is given on pages 790–792. The book remained in use as a signature-book for about ten years, but in 1755 a regular register was started, with the names and addresses of members, the amounts of their subscriptions, the dates when they became due, and the dates of their deaths or resignations. The first volume of this register contains the elections from 1755 to 1767, and it has been continued, almost in the same form, up to the present date. Then, as now, the book lasted for about ten years, and at the end of that time a fresh book had to be opened, the names of surviving members being transferred, and space provided for the receipt of new entries.

The first printed list of members was issued in October, 1755. It is a mere broadside, and contains 110 names. The next list which has been preserved is dated 1758, in which year the numbers increased to 708, and the next following 1760. From that date they go on regularly at

short intervals, until their regular annual publication. A careful examination of these lists affords very remarkable evidence of the popularity of the Society, of the way in which it rapidly attracted public support, and of the esteem in which it was held. A very large proportion of the peerage supported the Society with contributions and patronage. Men of distinction in every class of life subscribed, and there is hardly any class or rank without eminent representatives. When it is borne in mind that the whole object of the Society was the promotion of public welfare, and that not the slightest advantage or benefit was offered to individual members, the character of the list seems still more remarkable.

"As the condition of England in the middle of the seventeenth century brought about the foundation of the Royal Society and the popular and widely-spread interest in the investigation of science, so the condition of the country in the middle of the eighteenth century brought about the formation of the Society of Arts for the encouragement of the applications of science for the general good. As Dryden, Waller, Evelyn, and the literary coterie of the Restoration period largely supported the Royal Society, so the circle that surrounded Dr. Johnson took a lively interest in the success of the Society of Arts. The lines upon which the Royal Society were founded were not followed by the founders of the Society of Arts. The latter made an entirely new departure and were strictly original in their scheme. Their objects were national, and the members gave their money and their time not for their own private advantage, nor for the increase of their personal knowledge, but in an attempt to raise the productive powers of the nation itself."*

To justify these statements it seems worth while to give a selection of the most eminent names which are to be found in the lists of the Society's members for the first ten years of its existence. The latest list examined is that dated March, 1764.

The following may be taken to be a fairly complete list of the Peers whose names are given in one or other of the lists above mentioned. Many of the Peerages are extinct or have passed to the holders of other titles, and no doubt some may have been overlooked. The holders of courtesy titles have not been included, and it would be too much to hope that some mistakes have not been made in identifying individuals:—

Peregrine Bertie, (3rd) Duke of Ancaster. Raised a regiment of foot in the 1745 rebellion. Lord Great Chamberlain of England. The Dukedom became extinct on the death of his brother, the 5th Duke.

John, (4th) Duke of Argyll. He married the beautiful and witty Mary Bellenden.

John, (4th) Duke of Bedford. English Minister-Plenipotentiary at negotiations for Peace of Paris, 1763.

William, (4th) Duke of Devonshire. First Lord of the Treasury, 1756–7.

Augustus, (3rd) Duke of Grafton. He held various offices, and was the nominal head of the Chatham Administration, 1766.

Evelyn, (2nd) Duke of Kingston. He married the notorious Elizabeth Chudleigh, Countess of Bristol, who was afterwards convicted of bigamy.

George, (4th) Duke of Manchester. He was elected in 1761, when he was Viscount Mandeville. He became Duke in 1762.

George, (4th) Duke of Marlborough.

John, (1st) Duke of Montagu. Elected as (4th) Earl of Cardigan in 1775, and created Duke in 1766.

William, (2nd) Duke of Portland. When he died in 1762 his successor, William (the 3rd Duke), became a member. The latter was twice Prime Minister in the reign of George III.

Charles, (3rd) Duke of Queensberry. This was the cousin and predecessor of "Old Q."

Charles, (3rd) Duke of Richmond. Ambassador and statesman. In the Cabinet of the younger Pitt. Vice-President of the Society. His portrait appears in Barry's Picture.

James, Marquis of Carnarvon. Eldest son of the 2nd Duke of Chandos. He afterwards became the 3rd Duke, and the title died with him in 1789.

Charles, (2nd) Marquis of Rockingham. Prime Minister, and head of the Rockingham Administration, of which Fox and Burke formed part.

James, (8th) Earl of Abercorn.

Arthur, (7th) Earl of Anglesey. His title to the English Peerage was pronounced invalid.

John, (2nd) Earl of Ashburnham.

William, (2nd) Earl of Bessborough. Postmaster-General, etc.

John, (3rd) Earl of Bute. Prime Minister. He paid £40 as a "perpetual member."

George, (4th) Earl of Cardigan, afterwards (1766) created Duke of Montagu.

Robert, (1st) Earl of Catherlough.

Philip, (4th) Earl of Chesterfield. The celebrated Lord Chesterfield.

Smith, (11th) Earl of Clanricarde.

* H. B. Wheatley's account of the Society of Arts, *Engineering*, July 24th, 1891.

William, (2nd) Earl of Dartmouth.

John, (2nd) Earl of Egmont.

Charles, (2nd) Earl of Egremont.

Brownlow, (9th) Earl of Exeter.

Robert, Earl of Farnham. He was the 2nd Baron Farnham, and was created Earl of Farnham in 1763, but died without male issue, so the Earldom lapsed.

Washington, (5th) Earl Ferrers, younger brother of the notorious Earl Ferrers, who was executed in 1760.

John, (7th) Earl of Galloway. Elected in 1761 as Lord Garlies.

Charles, (1st) Earl Grey. General. Commander-in-Chief in America and the West Indies.

George Montagu, (3rd, and last) Earl of Halifax, K.G. First Lord of the Admiralty, Lord Lieutenant of Ireland, etc.

Simon, (1st) Earl Harcourt. Ambassador and Viceroy of Ireland. His eldest son, George Simon Viscount Nuneham, was also a member. He succeeded his father as (2nd) Earl Harcourt in 1777.

Philip, (2nd) Earl of Hardwicke. Elected when he was Viscount Royston. Vice-President of the Society.

Wills Hill, (1st) Earl of Hillsborough, afterwards (1789) Marquis of Downshire, Statesman.

Robert, (4th) Earl of Holdernesse. Ambassador and Secretary of State.

Francis, (10th) Earl of Huntingdon.

George, (3rd) Earl Lichfield, Chancellor of the University of Oxford, 1762. Vice-President of the Society.

John, (1st) Earl Ligonier. Field-Marshal. He served under Marlborough in Flanders, and received several steps in the Peerage, becoming Earl in 1766. He died in 1770 at the great age of ninety-one, and was buried in Westminster Abbey.

Henry, (9th) Earl of Lincoln, afterwards (2nd) Duke of Newcastle.

George Parker, (2nd) Earl of Macclesfield. P.R.S. He took an active part in the introduction of the New Style in 1751. Thomas, the 3rd Earl, was also a member. He was elected in 1757 as Viscount Parker.

Charles Henry, (7th) Earl of Montrath.

James, (8th) Earl of Moray.

Charles, (7th) Earl of Northampton.

Spencer, (8th) Earl of Northampton.

Hugh Smithson, Earl of Northumberland. Elected under that title in 1757. He was in 1766 created the 1st Duke of Northumberland.

Henry Herbert, (10th) Earl of Pembroke.

Other, (4th) Earl of Plymouth.

George, (2nd) Earl of Pomfret.

Henry Arthur, Earl of Powis (Lord Herbert of Cherbury). The extinct Earldom, after the death of his son, was conferred on the eldest son of Lord Clive.

Neil, (3rd) Earl of Rosebery.

John, (4th) Earl of Sandwich. The famous First Lord of the Admiralty, the inventor of the sandwich, which he ate when too busy for a meal. Known as "Jemmy Twitcher," from the character in the "Beggar's Opera," in consequence of his attack upon Wilkes, his former friend and associate at Medmenham Abbey.

Antony, (4th) Earl of Shaftesbury. He married a daughter of Lord Folkestone, and was one of the first subscribers, having given ten guineas to the original fund started in 1754 to provide prizes.

William, (2nd) Earl of Shelburne, Prime Minister in George III.'s reign, afterwards 1st Marquis of Lansdowne.

Harry, (4th) Earl of Stamford.

Philip, (2nd) Earl of Stanhope, the father of the Earl Stanhope who improved the printing-press.

Earl of Stirling. This was William Alexander, "Commander-in-Chief of the American forces," who claimed and bore the title after the death of the 5th Earl in 1739. He died in 1795.

Granville, (2nd) Earl of Sutherland, afterwards Marquis of Stafford.

Richard, (1st) Earl Temple, brother of the Prime Minister George Grenville.

Percy, (1st) Earl of Thomond.

John, (2nd) Earl Tylney. He was the grandson of Sir Josiah Child, the great merchant and economist, chairman and for long absolute ruler of the East India Company.

Ralph, (2nd) Earl Verney, F.R.S. At his death, in 1791, the title became extinct.

James, (2nd) Earl of Waldegrave, K.G. First Lord of the Treasury.

Francis Greville, (1st) Earl of Warwick. He was the 8th Baron, and first Earl Brooke.

Thomas, (8th) Earl of Westmorland. His eldest son, John, Lord Burghersh, was also a member. He succeeded his father in 1771 as (9th) Earl of Westmorland.

William, (2nd) Viscount Barrington, Chancellor of the Exchequer, etc.

John, (2nd) Viscount Bateman.

Frederick, (2nd) Viscount Bolingbroke.

James, (3rd) Viscount Charlemont, afterwards Earl of Charlemont.

Henry, (1st) Viscount Conyngham.

William, (2nd) Viscount Courtenay. The title became extinct with his son, who, however, had established his title to the Earldom of Devon.

John, (4th) Viscount Downe.

John, (1st) Viscount Dudley.

Lucius, (7th) Viscount Falkland.

Richard, (6th) Viscount Fitzwilliam.

Jacob, (1st) Viscount Folkestone. Founder and First President of the Society. His portrait by Gainsborough is in the possession of the Society, and Barry also included the portrait in his painting of "The Society."

Richard, (4th) Viscount Howe. The celebrated Admiral Howe, afterwards Earl Howe.

Charles, (9th) Viscount Irvine.

Thomas, (4th) Viscount Kenmare.

George, (3rd) Viscount Midleton.

Henry, (2nd) Viscount Palmerston, Father of the well-known statesman.

Edward, (2nd) Viscount Powerscourt.

George, (1st) Viscount Southwell.

John, (1st) Viscount Spencer, afterwards (1765) Earl Spencer. His son was the founder of "the finest private library in Europe," and the well-known statesman.

George, Viscount Townshend, the 4th Viscount and 1st Marquis. Field-Marshal, Lord-Lieutenant of Ireland, Brigadier-General under Wolfe in Quebec Expedition. He was elected in 1757 as General Townshend, before his accession to the Peerage.

Thomas, (2nd) Viscount Wentworth. His father, the 1st Viscount, was elected a member before his promotion, and his name appears in the list as Baron Wentworth.

Thomas, (3rd) Viscount Weymouth, K.G., afterwards (1789) created Marquis of Bath. Secretary of State and Lord-Lieutenant of Ireland.

George, (1st) Baron Anson. The great Admiral, First Lord of the Admiralty. Celebrated for his voyage round the world. He had no children, so his title died with him.

Frederick, (7th) Baron Baltimore. At his death the title became extinct. The first Lord Baltimore was the coloniser of Maryland in the reign of James I., and it was from him that the city of Baltimore took its name. Barry heard of Baltimore's charter to the Indians after he had finished the picture in the meeting room. So in his etching he made Baltimore a prominent figure, and thrust William Penn into the background.

Charles, (3rd) Baron Cadogan, afterwards (1800) created Earl Cadogan.

John, (1st) Baron Carysfort. Lord of the Admiralty.

Robert, (1st) Baron Clive of Plassy. The great Indian statesman and General.

Gabriel, (1st) Baron Coleraine.

Richard, (2nd) Baron Edgcumbe. He died in the year following his election, 1761, when his brother and successor became a member.

George, (3rd) Baron Edgcumbe, created Earl of Mount-Edgcumbe in 1789.

Thomas, (1st) Baron Foley.

George, (1st) Baron Lyttelton, scholar and author.

Thomas, (2nd) Baron Montfort.

Frederick, Lord North, afterwards (1790) 2nd Earl of Guilford. The eminent statesman, Prime Minister 1770 to 1782.

Francis, (1st) Baron Orwell, afterwards (1776) Viscount Orwell and (1777) Earl of Shipbrook.

John, (1st) Baron Pollington, afterwards Earl of Mexborough.

George, (1st) Baron Rodney, the great Admiral. He was elected in 1757 as Admiral Rodney, and was made a peer in 1782.

Robert, (2nd) Baron Romney. Founder, first Vice-President, and second President of the Society. His portrait by Reynolds is in the possession of the Society.

John, (11th) Baron St. John of Bletsoe.

Nathaniel, (1st) Baron Scarsdale.

Thomas, (3rd) Baron Southwell, created Viscount Southwell in 1776.

John, (1st) Baron Waltham.

John, (6th) Baron Ward, afterwards (1763) Viscount Dudley and Ward.

Edward, Baron Wentworth, afterwards (1762) (1st) Viscount Wentworth. His son was also a member, and his name is included among the Viscounts.

John, (6th) Baron Willoughby de Broke.

Hugh, (15th) Baron Willoughby de Parham. P.S.A., F.R.S., Vice-President of the Society.

Edward, (1st) Baron Winterton, afterwards (1766) Earl Winterton.

We may now leave the Peerage, and attempt a selection from the general body of members, dealing as before with the lists previous to, and including that of, 1764. The task of picking out the names of persons eminent at the time or afterwards distinguished has proved rather difficult. Without the help of that admirable work, the "Dictionary of National Biography," it would have been hopeless. Wider historical

knowledge, and a greater familiarity with the records of the time would, no doubt, have rendered the task easier and the results more complete. In many cases, also, the information given is too slight to render identification certain. The list, therefore, must be taken as representative rather than exhaustive, though probably there are not many names of real eminence that have been overlooked. At all events, the following list is so long that perhaps no apology is needed for not making it longer.

Robert Adam (elected in 1758) and James Adam (1763), the architects of the Adelphi. (The William Adam elected in 1762 was not one of the brothers.)

Anthony Addington, M.D., physician to the great Lord Chatham and father of the Prime Minister who was nicknamed "The Doctor," in allusion to his parentage.

Ralph Allen, philanthropist, improver of the Post Office, friend of Pope, Fielding, and others.

William Almack, founder of Almack's Assembly Rooms and of the gaming club afterwards known as Brooks's.

John Julius Angerstein, whose fine collection of pictures formed the nucleus of the National Gallery.

Thomas Arne, the well-known musician; composer of "Rule Britannia."

Robert Arthur, St. James's Street, proprietor of Arthur's and White's.

Thomas Astle, antiquary, Keeper of the Records, author of "Origin of Writing."

John Astley, portrait painter, and friend of Horace Walpole.

David Erskine Baker, author of "Companion to the Playhouse," enlarged to "Biographia Dramatica."

Henry Baker, F.R.S., naturalist and author. Defoe's son-in-law. Founder of the Bakerian lecture of the Royal Society. He took a very active part in the foundation and early organisation of the Society. He was elected a "perpetual member" in 1755 for his services.

Samuel Baker, founder of Sotheby's Auction Rooms.

Sir Joseph Banks, for forty-one years the autocratic President of the Royal Society.

Sir Francis Baring, founder of Baring Brothers and Chairman of the East India Company.

Robert Barker, the reputed inventor of panoramas.

Sir Edward Barry, physician, medical writer.

John Baskerville, the eminent printer.

Topham Beauclerk, the fashionable friend of Dr. Johnson.

William Beckford, Lord Mayor 1762 and 1769, the staunch supporter of Wilkes.

Jeremiah Bentham, the father of Jeremy Bentham, the great utilitarian philosopher. He was elected in 1755, when his son Jeremy was sixteen.

James Boswell, elected in 1760 when he was twenty, on his first visit to London and before he knew Johnson.

Alderman John Boydell, the reviver of English engraving by his munificent patronage.

Gustavus Brander, F.R.S., antiquary, director of Bank of England, benefactor to British Museum. One of the Society's founders.

Owen Salusbury Brereton, antiquary, Recorder of Liverpool, Bencher of Lincoln's Inn. Vice-President of the Society. His portrait is in Barry's picture.

Jacob Bryant, classical scholar.

Charles Burney, the well-known author of the "History of Music." He was elected in 1764, when he was living in Poland Street, and before he took the degree of Mus.Doc. His portrait appears in Barry's picture, "The Thames," amongst the sea-nymphs, "a whim equally absurd and incomprehensible, which no raillery or good counsel could induce" the artist "to dismiss from his canvas."

William Cadogan, M.D., physician to the Foundling Hospital.

William Caslon, the famous type-founder.

The Hon. Henry Cavendish, the great philosopher and experimentalist.

Sir Robert Chambers, one of the judges in the trial of Nuncomar.

Sir William Chambers, the architect of Somerset House. He acted as architect to the Society when it moved into new premises in Little Denmark Court, 1759.

Samuel Chandler, D.D., Nonconformist minister and bookseller.

Charles Chauncey, physician and collector.

Sir Henry Cheere, statuary, patron of Roubiliac.

Thomas Chippendale, furniture maker.

Giovanni Cipriani, R.A., historical painter and engraver.

George Colman the elder, dramatist.

Sir Eyre Coote, the famous Indian General and conqueror of Hyder Ali. At the time of his election he was Colonel Coote.

Richard Cosway, R.A., portrait painter.

James, Thomas, and Patrick Coutts. James at the time of his election was already a partner in the great banking firm, then in the "New

Exchange," and carrying on business as "Campbell and Coutts." Thomas was elected in 1762, the year after he had been taken into partnership, after the death of Campbell. Patrick was at the time of his election (1767) a partner in the bank in St. Mary Axe, first started by the Coutts.

Sir John Cust, Speaker of the House of Commons, 1761 and 1768–70.

George Dance, the elder of the two architects, father and son. He designed the Mansion House.

Sir Francis Dashwood (Baron le Despencer), Chancellor of the Exchequer, and leading member of the Dilettanti Society; founder of the "Hell Fire Club" at Medmenham.

Captain (afterwards Colonel) Thomas Desaguliers, F.R.S., son of J. T. Desaguliers, author of various books on mechanical and experimental philosophy.

Sir Alexander Dick, president of the Edinburgh College of Physicians and friend of Dr. Johnson.

Robert and James Dodsley, the well-known booksellers.

John Dollond, the eminent optician, Copley medallist.

Robert Dossie, the editor of the "Annals of Agriculture," etc., in which the Society's early Proceedings were recorded. He was a friend of Samuel Johnson, and the Doctor, being in arrears with his subscription, paid up in order to vote for Dossie when he was a candidate for the secretaryship of the Society in 1760.

Robert and John Drummond, the bankers, whose bank was then, as now, at Charing Cross, were both members. The former was elected in 1757 and the latter in 1762. Robert, who was the head of the firm, was the son of Viscount Strathallan, who was killed at Culloden and was attainted, as was also his eldest son. John married a granddaughter of the first Duke of St. Albans (Nell Gwynne's son), and it was through this connection that the Adelphi estate, acquired by the second Duke of St. Albans, on his marriage with the daughter of Sir John Werden, whose Trustees had purchased it, came into the possession of the Drummond family. The Drummonds have ever since been connected with the Society; and Mr. George James Drummond, the owner of the Adelphi, is now (1911) the Society's landlord. The bank was founded in 1688 by Andrew Drummond, the father of John, abovementioned.

Sir John Fielding, the magistrate, half-brother to the novelist.

Sir Samuel Fludyer, Lord Mayor in 1761. Fludyer Street, Westminster, was called after him.

John Fothergill, M.D., F.R.S., botanist and physician, associated with Franklin.

Benjamin Franklin, the great American philosopher and politician. He was elected a corresponding member in 1756, but paid the amount of a Life Subscription, and his name afterwards appears among the ordinary members. He kept up a correspondence with the Society, and in 1761, while in England, he accepted the office of chairman of the Committee of British Colonies and Trade.

David Garrick, the great actor.

Edward Gibbon, the historian.

Thomas Gisborne, M.D., President of the College of Physicians.

Oliver Goldsmith, whose address when he was elected in 1763 was the Chapter Coffee House.

Major-General Sir John Griffin, K.B., afterwards Field-Marshal, and (1784) (9th) Baron Howard de Walden.

Admiral Thomas Griffin, served in the West Indies and elsewhere, but left an unfortunate reputation for lack of intrepidity and for unpopularity.

Thomas Grignion, the clockmaker, who presented to the Society the clock in the meeting-room.

Francis Grose, antiquary and author.

Stephen Hales, D.D, F.R.S., Copley Medallist, physiologist, botanist and inventor. One of the Society's founders. His portrait is in Barry's Picture of "The Society."

Jonas Hanway, the historian of commerce and the introducer of umbrellas.

Sir Charles Hardy, Admiral, Governor of New York, served in command under Hawke at Brest and Quiberon Bay. M.P. for Portsmouth.

The Hon. Thomas Harley, afterwards Lord Mayor (1767), opponent of Wilkes.

Sir Edward Hawke, K.B., the distinguished Admiral, afterwards (1776) 1st Baron Hawke.

John Hawkesworth, LL.D., friend of Johnson, and his successor as compiler of the Parliamentary reports in the *Gentleman's Magazine.*

Sir Cæsar Hawkins, the eminent surgeon.

Sir George Hay, lawyer and politician.

Francis Hayman, original R.A., friend of Hogarth and Garrick.

William Heberden (the elder), physician and scholar; attended Johnson, Cowper and

Warburton. He, like Cæsar, wrote his "Commentaries," and a bookseller is said to have recommended one as a substitute for the other.

William Hoare, of Bath, original R.A. Distinguished portrait-painter.

William Hogarth. His signature is crossed out in the signature book; why, there is no saying. He was duly elected in December, 1755, and subscribed for two years. His name appears on committees in 1757. He died in 1764.

Thomas Hollis, republican and author. Presented portrait of Newton to Trinity College, Cambridge, and portrait of Cromwell to Sidney Sussex.

John Howard, the philanthropist.

Richard Huck, army surgeon and physician of reputation. In 1777 he took the additional name of Saunders.

Dr. William Hunter, the physician, who was as well known in his day as his younger brother John.

Dr. Robert James, the inventor of James's Powder.

Richard Jebb, M.D., afterwards (1778) baronet. Friend of Wilkes and Churchill.

Soame Jenyns, a great man in his day, but now best known as having had his "Nature and Origin of Evil" unfavourably reviewed by Johnson.

Samuel Johnson, whose only speech on his legs is said to have been delivered in the meeting-room of the Society of Arts.

Hugh Kelly, a playwright who considered himself a rival of Goldsmith.

Admiral Augustus Keppel, afterwards (1782) created Viscount Keppel.

Gowin Knight, M.D., F.R.S., Principal Librarian of the British Museum.

Sir Charles Knowles, Admiral, Governor of Louisburg and of Jamaica.

Abraham Langford, auctioneer and playwright.

Colonel Stringer Lawrence, called the "father of the Indian Army." He left India in 1759.

Thomas Lawrence, friend and physician of Dr. Johnson.

Sir Wilfrid Lawson, the eighth Baronet.

Henry Bilson-Legge, Financier, Chancellor of the Exchequer, etc.

James McArdel, one of the best English mezzotint engravers.

Robert Mackreth, the well-known waiter at Arthur's Chocolate House, known as "Bob," afterwards M.P., and knighted.

Sir Richard Manningham, known as a great "man-midwife."

William Markham, D.D., headmaster of Westminster School; afterwards (1777) Archbishop of York.

Matthew Maty, M.D., F.R.S., secretary R.S., Principal Librarian of the British Museum. He was a candidate for the secretaryship of the Society in 1760, when Dr. Templeman was elected.

Israel Mauduit, F.R.S., political pamphleteer and preacher. Agent in England for Massachusetts.

John Mitchell, F.R.S., botanist, made a map of the British and French Dominions in North America.

Sir Henry Moore, Bart., Governor of Jamaica and of New York.

Robert More, F.R.S., botanist. Afterwards secretary of the Society (1769 to 1799).

Charles Morton, M.D., Principal Librarian of the British Museum.

George Michael Moser, chaser and enameller, first keeper R.A. Engraved George III.'s first Great Seal. Father of Mary Moser, R.A.

Lieut.-Gen. Lord John Murray, M.P. for Perth.

Robert Mylne, F.R.S., constructed Blackfriars Bridge, engineer to the New River Company.

John Newbery, publisher and bookseller. He employed Johnson and Goldsmith.

Frank Nicholls, F.R.S., physician.

Lieut.-General Oglethorpe, M.P., founder of Georgia. Johnson offered to write his life. Austin Dobson calls him a "Paladin of Philanthropy."

James Paine, an architect who did much good in his time. He rebuilt Salisbury Street in 1783.

Sir Robert Palk, Bart., Governor of Madras. Palk Strait, between Ceylon and India, is called after him.

James Parsons, M.D., F.R.S., physician and antiquary.

Sir Lucas Pepys, Bart., M.D., President Royal College of Physicians, physician to George III. Attended the King in his insanity. He was elected in 1764, when twenty-two years of age.

John Lewis Petit, M.D., F.R.S., physician.

Constantine John Phipps, commanded the "Racehorse" in expedition of 1773 to discover north-eastern route to India, and attained a high north latitude to north of Spitzbergen. Afterwards (2nd) Baron Mulgave, M.P., and Lord of the Admiralty, etc.

Christopher Pinchbeck, inventor, son of the inventor of copper and zinc alloy named after him.

Charles Pinfold, Governor of Barbados.

Thomas Pingo, medallist, assistant engraver to the Mint.

William Pitcairn, M.D., President of the College of Physicians, 1775–85. A ward in St. Bartholomew's Hospital is named after him.

George Pitt, afterwards Baron Rivers, author of "Letters to a Young Nobleman," etc.

William Pitt, the great statesman, afterwards Earl of Chatham.

Admiral Sir George Pocock. He took Havana in 1762.

Sir James Porter, F.R.S., Ambassador at Constantinople.

Governor Pownall, politician. His work on "The Administration of the Colonies" went through several editions. He was elected in 1760, and his name in the List is altered from "Governor" to "Thos, Esq."

Sir Charles Pratt, afterwards created Earl Camden, Lord Chancellor and Chief Justice; decided in the case of John Wilkes that general warrants were illegal, and thereby gained immense popularity.

William, Viscount Pulteney, the son of the well-known politician who was made Earl of Bath by Walpole. He died before his father, and the earldom became extinct.

Sir Thomas Pye, Admiral. "A man of slender ability, thrust into office by the Bathurst influence."—*Dict. Nat. Biog.*

Allan Ramsay, portrait painter to George III., acquaintance of Johnson.

Sir Joshua Reynolds, first President of the Royal Academy. Elected in 1756 before he was knighted.

General Robert Rich (afterwards 5th baronet), wounded at Culloden.

Samuel Richardson, the novelist.

Sir Thomas Robinson, Governor of Barbados and Commissioner of Excise.

John Robison, went to Jamaica for the test of Harrison's chronometer.

Francis Louis Roubiliac, the sculptor.

Sir John St. Aubyn, (5th) Bart., M.P., F.R.S.

Lord George Sackville, afterwards Viscount Sackville, of unhappy reputation for his behaviour at the battle of Minden in 1759.

Paul Sandby, R.A., water-colour painter and engraver.

Sir Charles Saunders, K.B., Admiral, served on Newfoundland station, and First Lord of the Admiralty.

Sir George Savile, Bart., M.P., F.R.S., well-known independent politician, and Vice-President of the Society.

Gregory Sharpe, D.D., F.R.S., Master of the Temple.

Peter Shaw, physician and author.

Thomas Sheridan, author and actor (father of Richard Brinsley). Proposed by Garrick.

The Rev. Laurence Sterne, author of "Tristram Shandy."

John Stock, painter to His Majesty's dockyards. He died in 1781, leaving the bulk of his property, upwards of £60,000, to the Painters' Company, with instructions that the interest should be distributed to the aged blind, the poor of the Company, and others. He left £100 to the Society, with the condition that the interest should be applied for the promotion of drawing, sculpture, and architecture.

Sir Robert Strange, the eminent English engraver.

General William Strode. It was he who erected the statue of Queen Charlotte in the centre of Queen's Square, and that of William, Duke of Cumberland, in Cavendish Square.

James Stuart, author, member of the Dilettanti Society, generally known as "Athenian" Stuart.

George Stubbs, the well-known animal painter.

Robert Taylor, M.D., F.R.S., a well-known physician.

James Theobald, F.R.S., F.S.A. One of the first Vice-Presidents of the Society. He took an active part in the movement for obtaining a charter for the Society of Antiquaries. He died in 1759. He is mentioned several times in Nichols's Literary Anecdotes, but is ignored by the *Dict. Nat. Biog.*

Sir Noah Thomas, M.D., F.R.S., physician.

Bonnell Thornton, well-known wit and writer, member of the "Nonsense Club," which organised an "Exhibition of the Society of Sign-painters," in ridicule of the Society of Arts Exhibition (see "Dictionary of National Biography"). He only subscribed for one year, so perhaps the Society's methods did not commend themselves to him.

John Thornton, one of the first of the well-known Clapham family, the great evangelicals.

Henry Thrale, the brewer, Johnson's friend.

Jacob Tonson, great nephew of Jacob Tonson, Dryden's first publisher, employed Warburton and Johnson among others.

Rev. James Townley, headmaster of Merchant Taylors' School, author of "High Life below Stairs," friend of Hogarth.

Charles Townshend, Chancellor of the Exchequer, etc., and brilliant wit.

Jonathan Tyers, proprietor of Vauxhall Gardens.

Robert Vansittart, Regius Professor of Civil Law, Oxford.

Horace Walpole, the great connoisseur and well-known author and collector. Afterwards (1791) 4th Earl of Orford.

Joshua Ward, "Spot" Ward, the well-known quack and nostrum-monger, whose statue by Agostino Carlini decorates the Society's Hall. He acquired a fortune by the sale of pills and potions, and a reputation by his introduction of improved methods of making sulphuric acid.

Richard Warren, M.D., a well-known physician.

Sir William Watson, M.D., F.R.S., physician and man of science. Physician to Foundling Hospital.

Philip Carteret Webb, F.R.S., M.P. He was joint solicitor to the Treasury and a leading official in prosecution of John Wilkes.

Alexander Wedderburn, Lincoln's Inn, afterwards Lord Loughborough and Earl of Rosslyn.

Saunders Welch, a magistrate of Westminster, friend of Fielding and Johnson.

Benjamin West, R.A., the painter.

Samuel Whitbread, brewer, father of the better-known politician.

Caleb Whitefoord, wit and diplomatist. Friend of Franklin, Johnson, Goldsmith, and Horace Walpole. He was a Vice-President of the Society, and a very active member of it. He was instrumental in obtaining the portraits of Shipley and Templeman. The Society possesses his portrait by an unknown painter.

Charles Whitworth, M.P., Chairman of Ways and Means, 1774 to 1778. Knighted 1768. One of the first Vice-Presidents of the Society.

John Wilkes, elected 1758 when thirty-one years of age. He was proposed by his father Israel Wilkes, who joined the Society in 1757, and was a very active member, constantly taking the chair at committee meetings.

Sir Edward Wilmot, Bart., M.D., F.R.S. Physician General to the Army.

Sir John Eardley-Wilmot, Chief Justice, Common Pleas. Educated with Johnson at Lichfield.

Joseph Wilton, sculptor, foundation member of R.A., associated with Sir William Chambers, the architect.

Henry Sampson Woodfall, the printer of the "Letters of Junius," and conductor of the *Public Advertiser*.

Sir George Yonge, Bart., Governor of the Cape.

Christian Friedrich Zincke, enamel painter; produced many portraits in enamel.

Amongst the names which came up for election there were very few rejected, as would naturally be the case when the object of the Society was to collect subscriptions for a certain purpose. However, one was that notorious free-lance, Dr. John Hill, or Sir John Hill, as he called himself after he had been made a knight of the Order of Vasa by the King of Sweden. He was proposed for election, but was unsuccessful, as he also was when he tried to get into the Royal Society, so that he might put F.R.S. after his name in the titlepage of one of his books. The "Dictionary of National Biography" describes Hill as "a versatile man of unscrupulous character, with considerable abilities, great perseverance, and unlimited impudence." He appears to have been at loggerheads with all his contemporaries. He paid out the Royal Society for not admitting him by an attack upon them, which certainly found out some of the weak joints in the armour of that distinguished body. He tackled Fielding and got rather the worst of it. When Garrick spoke slightingly of a play written by him, he attacked him also. Garrick retaliated by the well-known epigram :—

> "For physic and farces his equal there scarce is,
> His farces are physic, his physic a farce is."

He does not appear to have been much affected by his rejection by the Society of Arts, though he wrote what was for him a temperate letter of protest.

From the first foundation of the Society ladies have been eligible for membership, and the lists of Members have always contained a certain number of women's names. The first list of October, 1755, contains the names of Miss Elizabeth Vaughan and Lady Betty Germain, daughter of the Earl of Berkeley, wife of Sir John Germain, who came with William the Third to England and served under him. She inherited a large fortune from her husband, and bequeathed it, in accordance with his desire, to Lord George Sackville, who took the name of Germain. She was a friend of Swift and other literary men. Miss Mary Cook—who, like Miss Vaughan, is now but an unknown name to us—was elected a little later in the same year (1755), and Mrs. Elizabeth Montagu—whose name is spelt Mountague in the list—the earliest "blue stocking" and the well-known authoress and leader of intellectual society, became a member in 1758. Her portrait appears in Barry's picture of the Society. Later lists include the names of the Countess of Denbigh, the Countess of

Macclesfield, the Countess of Northumberland, and Viscountess Falmouth.

There can be no doubt that the list from which the above names have been selected was a very remarkable one, and one which may challenge comparison with that of any other society, however distinguished. Statesmen, philosophers, philanthropists, painters, lawyers, divines, physicians, authors, dramatists, actors, musicians, bankers, soldiers, sailors, architects, historians, mechanicians, merchants, all are to be found, and many of them are the most eminent of the time. Besides these, there is a crowd of peers and wealthy men who seem to have been quite ready to support, with their purses and their influence, a scheme which commended itself as likely to promote the growing industrial and commercial interests of the kingdom.

Other evidence as to the early popularity of the Society, and of the public esteem in which it was held, is to be found in contemporary literature. Smollett, in his History* gives a full and laudatory account of the institution and proceedings of the Society: "The protection, countenance and gratification secured in other countries by the institution of academies, and the liberalities of princes, the ingenious in England derived from the generosity of a publick, endued with taste and sensibility, eager for improvement, and proud of patronizing extraordinary merit. . . . In a word, the Society is so numerous, the contributions so considerable, the plan so judiciously laid, and executed with such discretion and spirit, as to promise much more effectual and extensive advantage to the publick than ever accrued from all the boasted academies of Christendom."

Anderson, in his "History of Commerce,"* speaks of the Society as: "One of the noblest designs for the improvement of the Commerce of Great Britain which could possibly have been devised." Perhaps in both cases the laudation is a little exaggerated, but the quotations may serve to show the estimation in which the early efforts of the Society were held.

THE AGRICULTURAL POSSIBILITIES OF NORTHERN JAPAN.

The agricultural investigations of the Japanese Government have demonstrated that Japanese Saghalien is a good winter wheat country, and that Hokhaido Island (the north sea province) is suitable for the desired extension of the silkworm and rice industry. While it has been demonstrated that various grains can be grown in the above districts, the chief points of interest to foreign manufacturers of agricultural implements, flour-mill machinery, etc., is the fact that in Northern Japan the tendency is towards a more liberal spirit, the conditions being more favourable to changes from ancient methods in farming and other industries. The agricultural areas of Japanese Saghalien are not extensive, the country being mountainous, and until the timber is removed it will be impossible to estimate what proportion of the total area, exclusive of mountain regions, may be ultimately suitable for farming. The bottom lands north from Olomari to Toyohara are among the best in the world. The Japanese experimental farm at Toyohara has demonstrated that many kinds of fruits, vegetables, and grain, such as are cultivated in Canada and Norway, can be successfully grown in Japanese Saghalien. According to the American Consul at Yokohama, the Japanese Agricultural College at Sapporo, in Hokhaido, devotes much attention to fisheries as well as to the up-to-date scientific study of practical farming pursuits, including stock-breeding. A model farm is attached to this college, and about half the cost of maintaining the college is obtained from the college lands and farm products. The president of this college believes that the introduction of modern machinery, and the horse, into Japanese farming industries in Hokhaido, coupled with higher wages, will tend to bring about the adoption of foreign methods. He estimates that 1,000,000 acres are under cultivation in Hokhaido, and that another 1,000,000 acres are being cleared for farming purposes, following closely upon the removal of forests, etc. Of the total area of Hokhaido, 6,000,000 acres are nominally reserved for forests. In rice and silk, coal, timber, wheat, and other grains, apples, potatoes and onions, it is rapidly growing more important.

THE BRAZILIAN COCOA-PALM.

Pernambuco is situated in the centre of the tropical part of Brazil, within which the cocoa-palm grows most luxuriantly. The cocoa-palm seems to be indigenous to the district which extends from the vicinity of Bahia on the south to Parahyba on the north, but it attains its fully luxuriant and most prolific development in the vicinity of Pernambuco. The cocoa-palm is one of the most beautiful and attractive natural adornments of many of the public parks and private gardens of Pernambuco, often attaining a height of from eighty to ninety feet. The trunk is without branches, and the leaves which cluster in a tuft at the top are from fifteen to twenty feet in length. At the base of the leaves the nuts hang in clusters, the number varying from three to fifteen according to the age and condition of the tree. The United States Consul at Pernambuco says that the nut is first planted in its natural state with hull and fibre. At the expiration of about twelve months, or when the plant has reached a height of about three feet, it is transplanted and set out in rows about forty feet apart. If cultivated and irrigated the tree will produce at the end of five years, otherwise it will require about ten years to produce. Although the rainfall within the coast region averages about eighty inches per annum, it all occurs during the months of the rainy season, and often when it is of no service to certain vegetation. The summers are hot and dry, and young plants and trees need to be irrigated. There are two cocoa-nut markets in the city of Pernambuco, one for the green and the other for the mature or dried nuts. The green nuts, which are picked at about the end of five months, and before the real meat of the nut has begun to form inside, are composed entirely of water, which forms one of the principal and most popular beverages of the neighbourhood. The water is non-alcoholic, and when iced is converted into a most savoury refrigerant. Its action is diuretic. When the nut is partially mature the inside is sometimes extracted, and by the use of sugar and some other ingredients is converted into a popular confection. The meat of the dried or ripe nut is used exclusively for food, being usually seasoned and mixed with different provisions for flavouring purposes. The owner of one of the large plantations in Pernambuco has recently stated that he averaged about four shillings net profit per annum from each tree. The greater proportion of the nuts are consumed locally, but a considerable quantity is shipped to Rio de Janeiro and other cities of Brazil, and also to European countries, where the improved facilities for extracting the oil have greatly enhanced their value.

THE MOTHER-OF-PEARL INDUSTRY IN THE SOCIETY ISLANDS.

Mother-of-pearl shells are found on the Pacific coasts of North and South America, in the islands of the Pacific Ocean, in the Philippines, on the coasts of Australia and in the adjacent islands, on the coasts of India, and in the islands of the East Indian Archipelago, in the Persian Gulf, in the Red Sea, and in Zanzibar. In Russia mother-of-pearl is used for ornamenting church vestments, and in Austria for making beautiful articles for personal adornment; in Italy high-relief cameos are carved on mother-of-pearl shells, and in Turkey allegorical and ornamental designs are engraved on large polished shells, which are known as Jerusalem shells. Natives of a number of tropical islands make ornaments of the shells, and in the South Pacific they use mother-of-pearl

fish-hooks, which are so bright that no bait or other lure is necessary. In the colony of Tahiti, mother-of-pearl shells are found chiefly in the Tuamotu (or Low) Archipelago, which embraces the Tuamotu (or Paumotu) and the Gambier Islands, and extends in a south-easterly and north-westerly direction for a thousand miles, the greatest width of this belt of islands being 300 miles. While shells are produced in all the islands, they are found of good quality and in paying quantities in fewer than one-fourth of the lagoons, which are enclosed by the eighty-two islands comprising the Tuamotu Archipelago. The American Consul in Tahiti says that the most productive of the Tuamotu Islands are Mikueru, Takume, Takaroa, and Takapoto, of the first rank; Marokau and Ravehere, of the second rank; and Hao, Motutunga, Manihi and Raroia, of the third rank. Of the Gambier Islands, Mangareva, Akamaru, and Akena produce shells which are large and heavy, but their quality is not very good. The time for the opening and closing of the diving season, which usually lasts from the 1st of May to the 1st of November, and the names of the islands open for the season, are published months in advance in the official journal of Tahiti, together with the regulations to be observed and the penalties for their violation. Before the opening of the season Papeete merchants send to the islands schooners laden with supplies, which are stored in portable houses built chiefly of corrugated iron. The shells in the lagoons are regarded as the property of any natives of the colony who will dive for them, but as almost all the good divers live in the Tuamotus, they reap the profits of the diving season. The hours for diving are from 9 until 2. The diver paddles his canoe out into the lagoon and anchors it, and if he happens to hit upon a good place, he may not move his boat during the five hours. A basket to hold the shells is let down by a rope tied to the boat. On the end of another small rope, also tied to the canoe, is a piece of lead weighing from fifteen to twenty pounds. The diver, who wears only a narrow loin-cloth, places one foot upon the lead, and with the rope between his toes stretches the rope with one hand held against his chest, utters several loud yells to empty his lungs, refills them quickly with pure air, and descends rapidly, feet foremost, to the bottom of the lagoon. He tears the shells from their support, usually a piece of dead coral, to which they are firmly fastened. A good diver will go down from twenty to twenty-five times in the five diving hours. The colony of Tahiti has the best divers in the world. They dive from six to one hundred and twenty feet in their work, and remain under water a minute and a half for the average man, two to two and a half minutes for a good diver, and three minutes for a few exceptional experts. Among the pearl-divers of Ceylon the highest record is said to be one hundred and ten seconds. The shells produced in the Society Islands are of the black-edged variety, and are the best of the kind found in the world. As they are all brought to Tahiti for exportation, they are known in the markets of the world as Tahiti black-edged shells. The dark edge is from a half to three-fourths of an inch in width. The rest of the inside is of a bright pearly appearance, with iridescent hues around a wide border, including the dark edge. The largest shells come from the Gambier Islands, which are only four in number, not counting insignificant islets. A French man of science gives an account of a pair of these shells that measured 11¼ inches in width and 13 inches in length, and weighed twelve pounds, but shells of that size are extremely rare. Local schooners bring the shells in bags or in bulk to Papeete. The work of assorting the shells according to size and quality is done chiefly by native women, who also help men to pack them in strong boxes, with a capacity of about two hundred and twenty-five pounds each. Nearly all of the Tahiti shells are shipped by way of New Zealand to London, which is the world's greatest market for this article of commerce. Among the products exported from Tahiti, mother-of-pearl shells rank second in value, copra holding the first place, and vanilla the third. The quantity of shells exported varies considerably from year to year, the average being about 475 tons annually.

HOME INDUSTRIES.

The State Insurance Bill.—The Government expect that this Bill will be law within three months, but meantime criticism is becoming less restrained and more general. Mr. Lloyd George has met the doctors but he has not come to terms with them, and, unless he does so, the Bill must fail. At Birmingham, last Saturday, he said: "I cannot say that I care very much for this wrangle in the sick room," but is it quite fair to put it in that way? Rightly or wrongly, the doctors believe that if the proposals of the Government as to the terms upon which medical attendance shall be given are carried, medical men will be very unfairly treated, and they make out a strong *prima facie* case. There must be give and take if they are to accept the Bill. They cannot be compelled to work for payment they consider inadequate, and the Act would be a dead letter without them. One of the chief points urged by the British Medical Association is that there shall be an income limit of £2 per week for those entitled to medical benefit. It is understood that Mr. Lloyd George will not listen to this suggestion, but there is surely something to say against the £160 limit of the Bill as it stands. As Dr. Benjamin Brown has pointed out, an unmarried man in a shipyard might easily earn £3 or £4 a week. Some unmarried artizans in certain trades earn a good deal more. Yet as soon as he is ill or unemployed he will get help, if the Bill is unamended, just as a poor labourer with a large family. Can it be seriously said that such a man is fit to be considered an object of charity, or a suitable case for Government help? The average income of the people of England is under £40 a

year, and to subsidise a man with an income of £160 must mean that a great number of really poor people will be taxed to put money into his pockets. It will seem to many that the Bill should only apply to married men, and to them only when their earnings do not exceed a sum considerably less than £160 a year. Take again Clause 51, which provides that no distress or ejectment shall be carried out upon a tenant in receipt of sick pay, and that the landlord who is guilty of such procedure shall be liable to a fine of £50. It is hardly conceivable that Parliament will accept this clause. The small landlord is to forego his rent, but he is not to be excused the payment of rates and taxes on his property, for the reason that his tenant is a recipient of sickness benefit. How the clause would work in many cases is shown very vividly in a letter addressed by Mrs. Millie Richardson to the *Times*. Mrs. Richardson rents a weekly house, and underlets the rooms which she does not occupy to working people. If Clause 51 becomes law, she would have to let a lodger stay in his rooms twelve months if he were very ill without paying her rent, and through all that time she would have to pay her landlord rent. Mrs. Richardson asks how she could pay it. She has a husband and three children to keep, and to work very hard at charing to do this. Can it be seriously contended that Mrs. Richardson has a moral duty to her lodger to give him gratuitous shelter for a year because he is too ill to work, or that it would be anything but gross injustice to require her to do so? Mr. Lloyd George seems to deprecate discussion, but it is obvious that the Bill will have to be fully discussed and widely amended if it is not to work more harm than good.

The "Titanic."—The White Star liner "Titanic" was launched last week, and her sister-ship, the "Olympic," has sailed for New York. The "Titanic" is 882 ft. 9 ins. long over all, or 850 ft. between perpendiculars, her breadth is 92 ft., and her depth, moulded, 64 ft. 6 in. The "Lusitania" has a total length of 785 ft., and breadth of 88 ft. The measurement of tonnage is about 45,000 for the "Titanic," and 32,500 for the "Lusitania," but the actual displacements will be about 60,000 and 38,000 respectively. The "Titanic" and "Olympic" mark a great advance in size and capacity over anything previously built. But they are considerably slower than the great Cunard liners, inasmuch as they are only expected to average 21 knots at sea as against 25 to 26 for the Cunarders. In spite of the much greater tonnage of the new ships, their horse-power will only be about 46,000 as against about 70,000 to 75,000 for the "Mauretania," and they will burn about 500 tons of coal per trip less, which means a saving of over £1 per ton. The "Mauretania" has turbine engines only, the "Titanic" has two sets of reciprocating engines and one low-pressure exhaust steam turbine. The passenger accommodation on the "Titanic" is 2,490, and on the "Lusitania" 2,200. The crews are respectively 856 and 827. It is anticipated that the net earning power per trip of the "Titanic" will be considerably more than that of the "Mauretania," but the latter makes a round trip every three weeks as against one in four weeks for the "Titanic."

English and American Shipbuilding.—The allegation that ship-repairing and even shipbuilding is now being done as cheaply in the United States as in the United Kingdom would seem to be upset by the report of the British Consul-General at New York, who was requested to look into the matter. Repairs, he states, cost from 50 to 75 per cent. more in American than in British yards. The explanation of certain recent contracts which seem to disprove this is that American yards were absolutely depleted of work, and accepted unprofitable prices rather than close and disperse their staffs. A similar explanation is given to account for an American firm having some time ago secured the contract for some Argentine "Dreadnoughts." In offering these low prices they were assisted by specially low prices for plates, as the rolling-mills were equally badly in want of work. It would be strange, indeed, if the United States, under present conditions, had become our rivals in shipbuilding.

Incandescent Gas Mantles.—Not very long ago it was discovered that ramie was much more effective in the construction of incandescent gas mantles than cotton, for whereas in the case of cotton the separate fibres of the yarn employed are closely entangled, in ramie they remain pretty wide apart, and so present a larger glowing surface. Now it is reported that experiments with artificial silk show the fibres of this material maintain their individuality to an even greater extent than ramie, and the mantles themselves are said to be much more elastic, supple, and durable. The Deutsche Gasglühlicht Company of Berlin has been doing a good deal of research work on these lines, and it is said that they intend shortly to place a new mantle on the market, whose essential difference from existing types lies in the fact that it is made of artificial silk. It is claimed for it that it is specially adapted for street lighting, and for all purposes where high-pressure gas is employed.

High-Class Tailoring.—It is usually assumed that a West-End tailor has his own workshop, where his customers' clothes are made under proper sanitary conditions, but this is by no means the general practice. Even where there is a workshop, some of the clothes are sometimes given out to be made in the journeyman tailor's home, which is generally, if not always, in an overcrowded tenement house, or a small lodging in a poor district. Here, in the one living and working room, the clothes are spread out and stitched together. A conference has just been held between the representatives of the Association of London Master Tailors and the London and National Amalgamated Societies of Tailors and Tailoresses. After discussion, the representatives of the employers and

employed both agreed it was in the best interests of the trade that work should be done in workshops provided by the master tailors, and not in the journeymen tailors' private dwellings. But this decision only takes the form of a recommendation. There is to be a ballot of the whole trade on a point which primarily interests the general public, which has the matter in its own hands. It is only necessary to inquire before ordering clothes whether the tailor has his own workshop, and to go elsewhere if he has not. When a master tailor finds he is losing some of his customers he will soon look about for a suitable workshop.

The Birkbeck Building Society.—There is no reason to suppose that the directors of the Birkbeck Building Society have been guilty of any of the malpractices associated with the collapse of certain other well-known institutions. Heavy losses were incurred as a consequence of the run on the Bank last autumn, when over £3,000,000 of deposits were withdrawn, which compelled the Society to sell large blocks of its gilt-edged securities at low prices, entailing heavy losses upon it. Then the general fall in high-class securities has involved the Society in serious losses which have not been adequately provided for, and it was difficult to write down the share-capital in order to make provision for the loss incurred owing to doubt about the *status* of the shares. The share subscriptions are about £1,050,000, but shareholders could at any time ask for the repayment of their capital by handing in their shares, and it is not known whether the shares rank for payment in priority to the deposits, or *pari passu* with the deposits, or after the deposits. The constitution of the Society invited disaster. It got its capital on a building society basis, and its deposits on banking conditions, and it used its funds as if it were a trust company. It employed only 16 per cent. of its funds in cash in hand and with bankers, in money at call, and in short loans and advances to customers, whereas it placed 70 per cent. of its total funds in investments, and about 7 per cent. in mortgage and ground-rents. The shares should not have been repayable, but should have been the margin for the safety of the deposits, and received the profits after meeting expenses and interest, whilst a much smaller proportion of the funds should have been invested in securities, and a much larger proportion in loans to customers and in the discount of bills, so as to secure the means of drawing a larger proportion of the funds if necessary, without requiring to sell securities. The total liabilities are understood to be about £8,000,000, and were the Society to be reconstructed, and many of the securities retained, a large portion of the loss that has been incurred might be recovered. The number of shareholders at the end of March, 1910, was 19,666. In addition, there were 93,151 depositors, making a total of 112,817 accounts. Since March of last year the deposits have been reduced from nearly £11,000,000 to about £7,000,000.

CORRESPONDENCE.

IMPROVEMENTS IN THE TRANSPORT AND DISTRIBUTION OF GOODS IN LONDON.

Seeing my name mentioned in the *Journal* of the 9th inst., I venture once more to trouble you with a few observations.

I notice Mr. Gattie's friend says that he is "in entire disagreement with this statement," but I fail to understand the remark, as it seems to me the friend immediately proceeds to confirm my hypothesis. (*a*) I said, "It may be taken for granted that the bulk of orders coming by post arrive by the early morning deliveries." Mr. Gattie's friend amplifies, and states that nine-tenths of the large City and West-End houses collect the morning's mail by special messengers. Surely this implies the early morning post is very important. (*b*) Then I went on, "These orders are dealt with in the course of the day, and are ready towards evening for collection in order to be sent to various parts."

It must be obvious to those who are practically acquainted with such work that this does not mean that many orders are not ready long before the present collection time. On the contrary, it is self-evident that in order to complete each day's work a certain proportion must approach completion each hour throughout the day. The expression "towards evening" may not be clear to all, but I had in mind "any time after noon," in contradistinction to the "early morning." However, this does not help with the information which has been requested from Mr. Gattie.

Let us assume for the moment that Messrs. Maple, Shoolbred, and various others have a considerable number of orders executed and ready for collection, say, by 11 a.m. The Clearing House collects and the goods are loaded, say, on a Manchester and district train by 12.30. This train might arrive at Manchester by, say, 6.30, and at Rochdale, Oldham, &c., proportionately later. What happens to the goods? Do they remain in the Manchester "Clearing House" until the following morning? In London a train from these points reaches the Clearing House at, say, 4 or 6 a.m., and the goods are delivered as early as possible at the various large consumers' premises. What happens to the train while waiting for the load of return freight? Is not siding accommodation necessary?

If Mr. Gattie would kindly work up a specimen time-table it would be so much easier to understand his ideas. It is useless citing cases like the Tottenham-Bristol one, as, although I happen to know of another (Todmorden-Bristol), no one can seriously urge such cases of delay are general.

As I have stated, I am always in favour of anything that can be done to save time, but Mr. Gattie's references to "black magic" and to exceptional cases of delay do not help to make clear his programme.

S. CHAPMAN.

Mr. Gattie, to whom the foregoing letter has been submitted, writes as follows:—

It seems to me that Mr. Chapman's words are perfectly clear, and also that his statements are erroneous and misleading. Mr. Chapman's words are: "These orders are dealt with in the course of the day and are ready *towards evening* for collection in order to be sent to various parts." It is not "obvious" to anyone that "towards evening" means anything else but towards evening. By no stretch of language can the words be construed into an accurate statement of fact.

It must be remembered that Mr. Chapman originally endeavoured to prove that a train arriving at the Clearing House could not be unloaded and reloaded immediately, because the goods for the reloading would not be in the Clearing House at the time. It is amply clear that orders are ready for collection all day long, and not "towards evening," as stated by Mr. Chapman. A. W. Gattie.

OBITUARY.

Maung On Ghine, C.I.E., A.T.M.—The death occurred in London on the 10th inst., after an operation, of Maung On Ghine, in his fifty-fifth year. He represented the Province of Burma at the Coronation of King Edward VII., and it was in accordance with a suggestion of the Government that he came to London this year. He was well known in Rangoon, where his business life was spent in close association with the Bombay-Burma Company, and he was an active and public-spirited member of the Rangoon Municipal Council. In 1885 he received the personal title *Ahmúdan gang Tazeik-ya Min* (i.e., The Recipient of the Medal for Good Service), indicated by the letters A.T.M. after the name, and in 1879 he was created a Companion of the Most Eminent Order of the Indian Empire. He became a member of the Royal Society of Arts in 1900.

NOTES ON BOOKS.

Income-Tax. By F. B. Leeming. London: Effingham Wilson. 2*s.* 6*d.* net.

Mr. Leeming divides the tax-paying community into two classes—"those who don't pay what they ought, and those who pay more than they need"; and his work is "intended to lead the former into the right path, and to show the latter the absurdity of paying too much for want of very little trouble." There can be no doubt that a very large number of people, whose honesty otherwise is sufficient to pass muster, think it justifiable to make false returns of their income for the purposes of taxation; but it is a little surprising to learn from this book what a large number of persons err in the opposite direction—not, it is to be feared, from any altruistic desire to benefit the State, but simply because they cannot understand the somewhat complicated schedules and regulations with which the Income-Tax Commissioners supply them. It seems probable that in future the would-be evaders of the tax are likely to find their task more difficult, for the Commissioners are taking steps to secure more accurate returns, and also returns from many who have hitherto, by frequent changes of address and other devices, contrived to escape altogether. In view of this more stringent enforcement of the law, Mr. Leeming's book will become more valuable than ever to those who honestly desire to ascertain what their precise liabilities are. Undoubtedly, in many cases, these are not easy to discover, *e.g.*, what items are allowed as expenses, the precise circumstances in which the incomes of husband and wife are regarded as one, the allowances on life and accident insurance, the various conditions under which the tax may be recovered, etc. Points such as these Mr. Leeming discusses in great detail, and he illustrates them with cases with which, as an accountant, he has had to deal. His explanations are as simple as the extreme complexity of the cases permits, and the book deserves the careful study of all who have found difficulty in filling up their income-tax schedules correctly.

The Slide-Rule. By Charles N. Pickworth. Twelfth Edition. Manchester: Emmott & Co., Ltd.; London: Whittaker & Co. 2*s.* net.

The fact that this little practical manual has now reached its twelfth edition is a sure proof of its utility and excellence. The letterpress has been once more revised, and descriptions of several new slide-rules have been added. The book contains many hints, suggestions for solving formulæ, new methods of extracting cube-roots, etc., and is of great value to students in the solution of mathematical and physical problems.

GENERAL NOTES.

The Pearl Fisheries of Queensland.—Queensland has a coast line of about 3,000 miles, and products of the sea, including *bêche-de-mer*, found along the Great Barrier Reef, lobsters, oysters, turtles, etc., are of considerable importance as sources of profit. The pearl fisheries along the northern coast employ large numbers of people, chiefly Japanese and Chinese Malays. The pearls found in Torres Straits, near Thursday Island, the chief centre of the industry, are usually small, and their aggregate value inconsiderable, but the shells are marketed in large quantities. A pearl found in Queensland was recently exhibited in Melbourne. It weighed 32¼ grains, and was valued at over £1,000.

Giant Melons in Asiatic Turkey.—The American Consul at Harput says that both the water and musk-melon of Diorbekir are the largest he has ever seen. Water-melons grow in Diorbekir each as large as a flour barrel, and musk-melons but little smaller, only the musk-melon is rounder, like a pumpkin. These melons are grown in the bed of the Tigris, as after the spring rains are over, and the snows have all melted from the mountains, the river shrinks to comparative insignificance, and large tracts of the bottom land are thus exposed. This land is ploughed, and in each hill where the seeds are planted a quantity of pigeon manure is mixed in with the earth. There are people in Diorbekir engaged in breeding pigeons for no other purpose than to sell the manure to the melon growers. As the melons are growing over the moist soil of what was a river for six months of the year, no irrigation is necessary, and though it seldom rains during the summer, the melon vines never dry up. The meat of these water and musk-melons is, however, very coarse, not nearly so sweet as the melons of smaller varieties grown in other parts of the country.

Experimental Station for Rice Culture at Vercelli.—The establishment of an experimental station for rice culture at Vercelli has recently been authorised by Royal Decree. The institution will be supported by grants from the province of Vercelli, the various communes, the agricultural societies, as well as by subscriptions from the landowners and agriculturists of the district. Its object, as the name implies, will be the promotion and improvement of the cultivation of rice in this part of the country. It is anticipated that by systematic experiments, and by the gathering of first-hand information respecting the actual conditions of the cultivation of this grain in other countries, rice growers will be enabled to obtain from the institution, not only the most suitable varieties of seed for their land, but also practical advice for its cultivation and preparation for the market.

Trade of Port of Paris.—According to the latest statistics published, the total movement of the Port of Paris amounted to 10,940,525 metrical tons in 1909 (metrical ton = 19 cwt. 77 lbs.), exceeding that of the Port of Marseilles, which amounted to 7,803,793 tons during the same period. The quantity of merchandise discharged was 6,197,414 tons against 2,566,000 tons loaded. The enormous excess in the tonnage of the imports over that of the exports is characteristic of Paris, where the requirements of the population in provisions, fuel and raw material must of necessity be far greater in weight than the manufactured goods sent away. The quantity of merchandise in transit was 1,809,800 tons, whilst the local traffic amounted to 867,230 tons. The extension of the quays within the fortifications of Paris, which include the Seine, the canals of St. Denis and St. Martin, as well as the Canal de l'Ourcq, is upwards of 25 kilometres (about 15 miles).

The Chinese Cotton Industry.—In the Wei Basin, Central Shansi, is to be found some of the most fertile land in China. Here large quantities of cotton are grown. Hsing-ping is the main cotton-producing district in the Wei Basin. The cotton grown from the native seeds produces a shorter but stronger fibre than that produced from the American seed. The native gin is an ingenious affair. It consists of a corrugated iron roll about half an inch in diameter and about twenty inches long, set close to a wooden roll about three-quarters of an inch in diameter. The wooden roll is worked by a crank turned by hand. The iron roll is worked by a treadle-wheel. The wheel is about two feet in diameter, with a crank-pin about four inches from the axle. A rod connects the crank-pin with the treadle-stick, the latter being a rough tree-branch ending in three prongs. The workman stands with his right foot on the treadle-stick, by means of which he turns the iron roll, and with his left hand turns the crank which revolves the wooden roll, while with his right hand he places the cotton pods in the rolls. The rolls pull all the fibres off the seeds and carry them through, while the seeds drop without having been carried through. The cotton seed is used for oil.

German Emigration and Immigration.—While in 1908 the number of German emigrants showed a decrease of 11,813 persons over the previous year, the year 1909 witnessed a revival of emigration to the extent of 5,038 persons more than in 1908. Of the 24,921 emigrants, 18,315 departed from German ports. At the Dutch ports of Rotterdam and Amsterdam 4,536 German emigrants embarked, whereas in 1908 only 1,300 emigrants left those two ports. In previous years the province of Posen contributed the largest number of emigrants, but in 1909 Brandenburg (including Berlin) was responsible for the majority. In proportion to population the city of Bremen again shows the largest number of emigrants. As in former years, the United States was the chief goal of attraction, 19,930 emigrants out of the total of 24,921 journeying thither. British North America claimed 367, Brazil a like number, and other sections of the American continent 3,889. Australia received 178, Africa 26, and Great Britain 164 German emigrants. In spite of the emigration increase, the percentage of agricultural emigrants decreased in 1909. In 1907 nearly 2,000 emigrants of this class left Germany, as against 1,070 who departed in 1909. Male emigration is more pronounced than female, the ratio being three to two. The number of so-called immigrants arriving in Germany during 1909 was 127,618, but this figure includes those persons rejected and deported by the United States immigration authorities. The exact number of those returning from the United States, either voluntarily or compulsorily, was 80,900; from the West Indies and Mexico, 981; from South American States, 8,499; from East Africa, 1,374; and from Australia, 616.

CARMICHAEL THOMAS, JOHN M. THOMSON, } *Treasurers.*

H. T. WOOD, *Secretary.*

KNOX, CROPPER & Co., *Auditors.*

Society's House, Adelphi, 20th June, 1911.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Fifty-Seventh Annual General Meeting, for the purpose of receiving the Council's report and the Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held, in accordance with the By-laws, on Wednesday, June 28th, at 4 p.m.

(By order of the Council),

HENRY TRUEMAN WOOD, *Secretary.*

EXAMINATIONS.

The results of the Advanced Examinations (Stage III.) will be published at the end of the present month.

The results of the Intermediate Examinations (Stage II.) will be published during July, and those of the Elementary (Stage I.) in August.

SCIENCE AND INDUSTRIAL APPOINTMENTS.

To what extent is there a demand for men of scientific training in the industrial and commercial world? This question has been forced upon the attention of the writer by the extraordinarily conflicting accounts which reach him from different sources. On one side he is told that the demand is at least as great as the supply—that practically every well-trained man of science, unless he is handicapped by some personal blemish of mind or body, may make sure of earning a reasonable living in some branch of industry. On the other hand, he hears bitter complaints from Oxford men of high academic qualifications—some even of

Fellowship standing—that, do what they will, they are driven to teach. One such person—who was formerly a tutor at one of the best Oxford colleges, and who, being unwilling to teach, has found himself compelled to abandon science for another profession—writes that half the men who took first classes in science in his year are earning £120 per annum teaching chemistry, and the rest have drifted out of science altogether.

Complaints of this nature are necessarily made in private; no attempt has been made—probably none could be made—to ascertain the number of men of sound scientific training who, though anxious to enter some branch of industry, have been forced to teach for a living. There can be little doubt, however, that they are fairly numerous. And this state of things, by the way, means a fourfold disaster. It is disastrous for the men who are driven into a profession they dislike; it is disastrous for their little victims, who cannot be expected to catch much enthusiasm for science when their teachers are suffering from boredom; it is disastrous for the profession which becomes overcrowded with underpaid and discontented drudges; and it is disastrous for the industries which might reasonably be expected to profit were the energies of these unfortunate men directed into more congenial channels.

From the very nature of the case, therefore, it is difficult to obtain any evidence in black and white showing the nature and extent of the trouble complained of; but something of this sort is furnished in an Appendix to a Report on the Revision of Regulations for the Award of Senior County Scholarships, issued in 1910 by the Education Committee of the London County Council. One scholar "obtained Ph.D. (Leipsic) and is now holding a Salters' Company's research fellowship. Hopes to obtain post in industrial world, but regrets that there seems very little demand for men with his training." A second, "after graduating Ph.D., has vainly endeavoured to obtain post as chemist in an industry for which he feels a natural inclination, his only chance being an offer of £80 per annum. He regrets being practically compelled to take up teaching." A third, "although a fully-qualified electrical and mechanical engineer, states that he has been unable to find permanent daily commercial employment, even at a bare living wage." A fourth "states that the market is flooded with highly-trained teachers of chemistry and physics who are thus compelled to accept small salaries . . . He regrets that at present the men sent to Oxford and Cambridge are mostly driven to become teachers." A fifth "is an Associate of the Royal School of Mines and B.Sc. (Engineering). Since 1908 has been unable to secure employment."

But, although there is a decided current of complaint in this document, its evidence as a whole is by no means unanimous. Out of ninety-three men scholars, six have obtained appointment as engineers, and nine as chemists in works, whilst one "states that Council scholars are doing useful work in the great industries."

Mr. Robert Blair, Education Officer of the London County Council, was at great pains to collect evidence on the point under discussion, and he summarised it in an extremely interesting address entitled "The Relation of Science to Industry and Commerce," which he delivered before the British Association at Sheffield last year. He sent some five hundred letters of inquiry to teachers of repute at home, in France, Germany and America; to representative firms of employers, and to thirty of His Majesty's Consuls in Europe, Asia, and the two Americas. He is of opinion that, upon the whole, the evidence placed at his disposal shows a tone of great hopefulness. With regard to agriculture, it would appear that those who have been trained in agricultural colleges have generally found posts in this or in allied industries. "The evidence from the engineering colleges and institutions," writes Mr. Blair, "is also, on the whole, satisfactory. Here and there may be found somewhat doleful notes to the effect that the large majority of State and local authorities do not lay themselves out to take advantage of technically-trained men, and, in one case, a view that has much popular currency has been put to me in fairly strong terms. It is to the effect that employers, especially those who have not very large and important undertakings, but who, nevertheless, would have their businesses improved by securing technically-trained men, have an ignorant prejudice against such assistance. It is suggested, as the possible explanation of their attitude, that the employers fear that, if they engaged men of greater attainments than themselves, they would simply be raising up possible opponents in their own line of business. There may be much truth in this view, which does not, of course, apply to first-class firms. But there is, I think, another view worth full consideration—that the size of the business concern (the amount of capital sunk in it) has much to do with the employer's attitude. The employer does not possess the faith that will

enable him to risk the addition of another salary to his working expenses; and no one, without a fair trial, is able to give him the mathematical demonstration which he seeks that the salary might often be saved merely out of the waste of materials which exists owing to the absence of scientific knowledge on the part of his men of the materials they are handling, and to their having to feel their way by experiments that are more in the nature of guesses. Such firms will be converted only by the example of others."

Upon the whole, then, it would seem that in the case of agriculture and engineering we are now fairly alive to the necessity of the man of science. How is it with industrial chemistry? It is, unfortunately, difficult to procure any but the sketchiest of statistics. In most cases of this sort appointments have been made through the personal recommendation of professors, and, as a rule, the universities and colleges have not kept records of their students' after careers. Even when such records do exist, the authorities seem very reluctant to make them public. Of course, a great deal of the work done by the appointments boards is of a highly confidential nature, but it is hard to understand why some information cannot be given in general terms—terms so general that they would not lead to the identification of the persons in question—as to the number and nature of the posts obtained.

Mr. Blair, who has also suffered from the difficulty of obtaining precise statistical details, is of opinion that a change for the better is coming over the country in this respect. He writes: "One of the largest technical institutions says: 'We are fairly sure of placing at once all the best men who have taken a graduating course in any branch of applied chemistry.' Another technical institution—probably the largest—states: 'We have been unable, during the last three or four years, to meet all the demands upon us for trained chemists, and at this moment we are unable to make nomination to two or three most important posts for which chemists are required, because all our men are satisfactorily placed.' From one of our oldest universities comes the statement: 'There is no difficulty in placing chemists of the highest rank in first-rate technical posts. By highest rank, I mean people with approximately Fellowship standing and great originality.' Sir William Ramsay writes: 'Some months ago I had the curiosity to pick out from my class lists, back to about 1890, a hundred names of men (and women) whose subsequent history I know. The result was, roughly: Sixty in industry (analysts, private or in works, managers, proprietors of works, etc.); twenty-five in teaching posts (assistants in universities or university colleges, schoolmasters, and a few professors—about six); and fifteen given up (married women, men who have changed their profession or dead).'"

It seems to be beyond a doubt, then, that in certain industries, at least, there is already a fair demand for men of first-rate scientific training. It is also quite as certain that the complaints heard in many quarters concerning the difficulty sometimes experienced by such men in securing industrial appointments have some basis in fact. This seems to point to a serious lack of organisation in the market, and careful investigations confirm this conjecture. What, then, are the present conditions? If a manufacturer wants to find a chemist to conduct researches in his works, does he know where, as a matter of course, he ought to go for his man? It would appear that it is very much a matter of chance whether he has such knowledge or not; still more a matter of chance whether the chemist knows where to go for an industrial appointment. In very many cases, as has been already said, such posts are obtained on the personal recommendations of professors. The manufacturer may know a professor of chemistry, the brewer may know a professor of brewing, and in either of these cases a satisfactory appointment may result; but if, as is still too frequently the case, the manufacturer has no acquaintance with the world of science, the chances are that he will either find an inferior chemist who will teach him a hearty contempt for science, or, rather than be troubled with elaborate inquiries, he will decide to continue working on the lines of his fathers before him.

And this is a state of things that ought to be altered as soon as possible. Not only ought no difficulties to be placed in the way of the business man who wishes to employ a man of science; every effort ought to be made to encourage him.

If the universities are to interest themselves in this matter—and, after all, it is they who are mainly concerned, for comparatively few men of first-class scientific attainments are trained elsewhere, and in the future there will probably be fewer and fewer—it would seem that the natural agency for promoting co-operation between science and industry should be the Appointments Boards. The Oxford Committee for Appointments has been run in an admirable but,

unfortunately, a very limited way. The appointments made through it have been almost entirely of a scholastic nature, and very little attempt appears to have been made to widen its scope. During the past three or four years some efforts have been made to induce business firms to take Oxford graduates, but so far with practically no success—a state of things which may, perhaps, be taken to account for the apparently general failure of the Oxford science man to find a footing in the industrial world. It is, too, a doubtful point whether the industrial world is aware even of the existence of an Oxford science school. That the Cambridge scientific man, on the other hand, is well known and appreciated there will be shown, it is hoped, later on.

The problem in London, owing to the size and sporadic nature of its university, is peculiar. Three or four of its constituent colleges would, in point of numbers and equipment, make respectable universities in themselves, and they have hardly as yet learnt to work together as a whole. Some two or three years ago the Senate did establish an Appointments Board, but, owing to initial difficulties, it has not yet been able to accomplish anything in the way of securing industrial posts. This, however, does not by any means imply that London has been doing nothing in that direction. For instance, the Central Technical College (now forming part of the Imperial College of Science and Technology) has won such a reputation as a school of engineering that practically all its students are sure of finding employment as soon as they leave. University College, some years ago, started an Appointments Board of its own. Unfortunately, for various reasons, it has not yet proved a great success; but some of the individual professors—notably, Sir William Ramsay, as has been already seen—have provided many scientific recruits to industry. At King's College, too, a number of men have secured such posts through their professors.

Most of the younger universities have followed the example of Oxford in instituting Appointments Boards, but inquiries addressed to these have only elicited very disappointing replies. This is possibly due to the fact that whereas the boards are beginning to be generally known as agencies for scholastic work, only few people have as yet learnt to apply to them for persons to fill industrial posts. Thus at Manchester the appointments registered are nearly all scholastic; industrial posts are generally obtained on the personal recommendation of professors, and it is impossible even to guess at their number and nature. The Clerk to the Senate at Leeds writes: "It is difficult to give any exact figures as to the numbers who have obtained appointments under the present arrangements, but the appointments themselves include engineering, dyeing, textile, and industrial posts." The Secretary of the Appointments Committee at Liverpool writes: "It is not possible to give exact figures as to the number of posts we have already filled in commercial and manufacturing firms. A considerable number of our men are employed in local chemical and engineering firms. I should say the number of such appointments in the neighbourhood of Liverpool is about fifty. Our work is not yet as widely known as it should be, a few firms only applying to us from time to time as vacancies arise."

The Registrar of Birmingham University writes: "The professors are in touch with leading manufacturers and mine-owners, and up to the present time have had no difficulty in placing the students when they have obtained their degrees, and are ready to commence practical work. In a considerable number of cases students in pure science, such as chemists, are also taken on by manufacturers, but I am afraid I have no record of these appointments, and cannot give an estimate of the number per annum."

There is nothing very definite in these replies; the letters from the other universities—English, Scotch and Irish—are even vaguer. But if they show nothing else, at least this fact emerges, that the Appointments Boards have not yet come to be recognised as the normal means for securing the co-operation of science and industry. To this rule there is one notable exception. The Cambridge Appointments Board has not yet been mentioned, because it stands apart from the rest. Founded in 1902, it has been conducted with much wisdom and success. By careful selection, in the first instances, it rapidly won the confidence of several of the most important business firms, who now return to it as a matter of course whenever they have any vacancies. Their example has naturally been followed by other firms, and the books of the board now contain many of the best-known names in the commercial world. Appointments—and valuable appointments, too—have been secured in numerous industries: in engineering, as chemists in works, in brewing, dyeing, alkali, shellac, soap, lead, glass, varnish, and many other industries;

in fact, the secretary reports that he has practically no difficulty in placing any man whom he can confidently recommend. A more recent and exceedingly interesting development is the securing of purely commercial posts by Cambridge graduates. During the last year some fifty men were settled in important administrative positions in business through the instrumentality of the Cambridge Appointments Board. This result has not been obtained, of course, without wise planning and energetic action. By its constitution, the board contains a number of eminent business men, whose advice is invaluable; while the secretary himself is in close personal touch with commercial and industrial firms in London and other parts of the country. The example of the Cambridge board and its businesslike methods ought certainly to be followed by the other universities.

Another body which is doing excellent work in this respect is the Institute of Chemistry. A register was recently started by the council on which anyone who has passed the examinations of the Institute may enter his name. This register has proved extremely successful. It has not been found possible to obtain figures as to the number of appointments made through its agency, but the registrar states that he has no difficulty in finding employment for all candidates whom he is able to recommend; indeed, the demand is now greater than the supply. He attributes this success largely to the fact that the Institute examinations are known to be of an exceedingly practical nature; and business men, when they secure the services of an Associate or Fellow of the Institute, feel confident that their employee has had something more than a mere academic training. The council are very much alive to the necessity of encouraging the union of industry and science. Many of the Fellows are, of course, men of great prominence in the industrial world, and they know—none better—the requirements both of science and industry. With a view to making these requirements more thoroughly understood, the council are proposing to institute a series of lectures to be delivered by chemists practically engaged in various branches of industry, who will describe the precise nature of their work in its actual conditions, and show how these differ from the conditions of pure science. It is also proposed to ask Fellows having expert knowledge to give students an insight into the actual work of the chemist. Such experience should prove of the utmost benefit to young chemists, for it is always found that the greatest difficulty lies in taking the first step from pure to applied science. Many business men who will fight shy of a graduate, however brilliant his qualifications, if he has only his academic qualifications to recommend him, will be glad to engage him if he can show even a short record of work under industrial conditions.

So much, then, for the avenues by which young men of science may hope to pass to industrial appointments. Let us now consider for a moment the steps which some of our leading firms are taking to secure the co-operation of science. Of course, in many kinds of works the chemist has long had a recognised position on the staff, but it is only of recent years—and it is among the most encouraging signs for the future of British industry—that any of our great business houses have expended money on purely scientific research on the chance that discoveries might be made which might prove of value to the industries with which they were concerned. Let two examples suffice.

For the last ten years Messrs. Arthur Guinness, Son & Co., Ltd., have maintained a research laboratory of their own, under the direction of Dr. Horace T. Brown, F.R.S., who is assisted by a chemist, a botanist, and two "administrators." The laboratory was founded with "the object of carrying out a systematic series of investigations on the varying nature of barley, and the complex changes which it undergoes during the early stages of the germinative process." These investigations offered a large number of extremely difficult and complicated problems—chemical, biological, and agricultural—which, at the time of the establishment of the laboratory, had hardly been so much as formulated. But of their importance alike to pure science and to the brewing industry there could be no doubt. Thus, as Dr. Brown wrote in 1903, "could we determine, in the early stages of the germination of a grain of barley, all the 'down-grade' chemical changes of the nitrogenous substances stored in the endosperm, and follow the products as they enter the embryonic plant and are once more built up into proteid, we should have a key to many obscure problems connected with the life processes of plants and animals; hence any investigation like the present must have a scientific interest and application reaching far beyond the scope of a mere technical inquiry." A large amount of research work has been carried out in the laboratory, and the results have been published from time to time. That the firm have not suffered financially

from their belief in pure science, their dividends seem conclusively to prove.

The well-known firm of Messrs. Burroughs, Wellcome & Co. have also been great pioneers in this respect. In 1896 Mr. Henry S. Wellcome founded the chemical research laboratories in King Street, E.C., which bear his name, and which have since been conducted under the direction of Dr. Frederick B. Power. The investigations conducted here have been of a very varied character and wide range They have comprised, amongst other subjects, the complete chemical examination of a large number of plants or plant products, which, on account of their reputed medicinal value or other properties, have been considered of special interest. Over a hundred papers, giving the results of these investigations, have been published in various scientific periodicals, and these have been freely distributed to those interested in the subjects of which they treat, and to such institutions and libraries as desire to preserve a record of them.

Mr. Wellcome also founded the physiological research laboratories at Herne Hill, where investigations are carried on under Dr. H. H. Dale in connection with physiological phenomena generally, and more particularly with the study of sera and anti-toxins. Much very useful work has also been achieved in the standardisation of drugs—a most important point, considering the extraordinary potency of many of the drugs in common use to-day. Both these institutions are independent of the business organisation of the firm, and are under separate direction.

Quite apart, however, from the chemical and physiological research laboratories, Messrs. Burroughs, Wellcome & Co. carry out a large amount of scientific investigation at their own works. Chemical, pharmacological, and botanical research is now conducted under most suitable conditions in the laboratories of the Wellcome Chemical Works at Dartford, where a number of highly-trained scientific workers are employed, and where very valuable inquiries into the nature and standardisation of drugs, sera, anti-toxins, etc., have been conducted.

But while, in the work of such firms as have been named, one rejoices to see signs that British industry is awaking to the necessity of calling in the aid of pure science, one must not be cajoled into the hope that we have as yet touched more than the fringe of the problem. Mr. Blair—if one may quote him once again—states his opinion thus: "I see no reason for believing that the number of highly-trained chemists who find their way from colleges into industrial chemistry is anything else than insignificant compared with similar figures for Germany or the United States of America." Our awakening has been at best but partial; certain trades appear to be still very sound asleep. It is, perhaps, invidious to name any branch as being more somnolent than the others, but it may be noted as a significant fact that recently, when an admirable course of lectures on brick-making was delivered before this Society, very few of the many round London who are supposed to be interested in the trade took the trouble to attend, although a certain Continental firm thought it worth their while to send a representative from Germany. And it is to be feared that this attitude is only too characteristic of the two nations generally. German manufacturers are eager for scientific knowledge, and will take any amount of trouble to secure it. In many cases the British manufacturer turns up his nose when it is offered to him. The results of this difference of attitude may be seen in a hundred directions, in none, perhaps, more strikingly than in the case of the aniline dye trade and in the steel trade which, once practically British monopolies, have now, thanks to the up-to-date and scientific development of German plant, become, to a large extent, German industries. Nor are the Americans less alert than our Continental rivals. A short time ago a society was founded in London for the study of paint and varnish. As soon as its establishment was announced numerous inquiries for its papers were received from the United States; none from people in this country.

Indeed, we have as yet but little ground for complacent self-satisfaction. Vast fields of industrial enterprise still lie untouched by our men of science—fields, too, in which other countries already provide us with striking object-lessons. Take the meat industry, for instance, The question of utilising the residual products in this branch is comparatively untouched in the United Kingdom. Here the number of by-products derived from a bullock is about ten, while in the large packing-houses of Chicago and the River Plate it runs to something like a hundred. Every part of the animal is used for some purpose or other, and there is absolutely no waste; and it is for this reason that foreign meats, equal in quality to our own produce, can be sold for a penny and twopence a pound less than the British article in the United Kingdom, notwithstanding all the intermediate charges which have to be made for transport, refrigeration, handling, etc. If some means were taken to

collect the large quantities of meat-trade residues which are available in this country, there is no doubt that they could be put to very profitable use, and at the same time prevent the huge waste which at present takes place. The case is very much the same with the fish industry. True, at certain centres, notably Montrose, Fraserburgh, Grimsby, Fleetwood, and Milford Haven, there are factories specially designed for dealing with the residual products, but in the other great fishing centres the raw material of these products (fish-oil, fish-meal, and fish-guano, for all of which there is a demand greatly in excess of the supply) is simply barged out to sea and wasted.

These are but two examples taken at random. It would be easy to multiply instances almost indefinitely, but perhaps enough has been said to indicate how vast is the scope of the problem before the man of science in the industrial world. Practically every department of trade is crying out for him, and offering, too, substantial rewards for his services. Who can say what branch does not hold a chance of repeating the success of Sir William Perkin, who created a great new industry by finding a use for a hitherto worthless material?

Let us hope, however, that it is no longer necessary to labour the point of the importance of science to industry. That was not so much the object of this article as to show that there are numbers of first-class men of science eager but unable to enter the industrial field (in which there really exists plenty of scope for them); and, secondly, to see if there are any means by which the men and the posts can be brought together. It appears to the writer that the Cambridge University Appointments Board has gone far to solve the problem. Let the other universities follow this example, modelling their work on the broad and liberal lines which Cambridge has adopted, and placing themselves in touch, as she has done, with the industrial world. There are now seventeen universities in the United Kingdom. If there were as many boards in full swing throughout the country, they would soon become known among manufacturers and men of business, and recognised as the legitimate channels of communication between science and industry.

G. K. Menzies.

BEDOUIN DESERT BREAD.

The "samh" is a small plant which grows wild, the Bedouins say, all over the desert plateau east of Maan on the Mecca railway, where nothing is cultivated, there being insufficient rain for any grain to grow. The plants grow close together, with short stems like lentils. The Bedouins pull them up by hand, and beat them with a stick, which has the effect of removing the small seed-pods. These are then taken to the wells, and holes are made in the sandy clay soil and filled with water. The seed-pods are thrown into these holes in small quantities, and stirred by the women, with sticks and their bare feet. The action of the water opens the pods, the seeds fall to the bottom, while the hulls float. Only about ten minutes in the water are required to open and separate them. The hulls are then skimmed off and the operation repeated. When sufficient pods have thus been treated, the water is dipped out and the seeds spread out to dry. The seeds are then sifted through fine sieves, to take out as much of the grit as possible, and ground in basalt handmills into flour, and the bread is either baked on a "saj"—a convex sheet iron of circular form, placed on small stones and heated, from underneath generally, with a manure fire—or in a "taboon," a dome-shaped clay oven, with an opening at the top, which is kept hot by a smouldering fire on the outside, always kept burning, and the floor is covered with pebbles on which the loaves are laid and baked. The bread is very black and gritty, the latter being accounted for by the way the seeds are hulled in the sandy holes. To improve the bread the natives add a little sugar to the flour, or a kind of molasses made from the seeds of the juniper tree (*Juniperus phornicea*) by boiling and then straining them. The juniper grows wild abundantly around Petra and the neighbouring mountains. The plant grows in a clayey, sandy, saline soil, and where very little rain falls; it ripens about the same time as barley, but, unlike most other plants, the seed-pods do not open when ripe. They are affected by dampness but not by heat, which enables the Bedouin to collect them throughout the summer.

THE DISTILLATION OF ORANGE FLOWERS AT GRASSE.

The distillation of orange flowers on the French Riviera, and particularly in the district surrounding Grasse, is a very important industry. Here 3,000 tons of these flowers are produced annually, not including the leaves and even the young fruit of the orange, which is also utilised for making the essential oil, so valuable in the manufacture of perfumes. The best quality of oil, called *néroli*, is obtained from the flowers of the wild, or bitter orange tree, locally termed *bigaradier*. The flowers of the sweet orange are not so productive, and yield a quality known as *néroli doux*, which is inferior to the other. A still more inferior quality is obtained from the *brouts* (the leaves and newly-formed fruit), this quality is called *petit grain*.

The flowers are gathered during the month of May. For their distillation an ordinary still may be used, but a special apparatus is preferable.

These are of smaller size at bottom than those employed for distilling spirits, and somewhat higher; a grating is also provided, so that the flowers and leaves are not in direct contact with the fire. An ordinary-sized still should contain about 40 kilogrammes of flowers (88 lbs.), and between 50 and 60 litres (11 and 13 gallons) of water. This should yield from 30 to 40 litres (6 to 8 gallons) of liquid.

The products of distillation pass from the still into a receiver, so arranged that the condensed liquid always remains at the same level in it, the water is drawn off from the bottom by a bent tube, whilst the globules of essential oil that float on the surface are collected at the top of the vessel. The oil, though not very soluble in water, is sufficient to impart its perfume to it, and is sold as *eau de fleur d'oranger*, whilst that obtained from the distillation of the leaves is termed *eau de broute*. A kilogramme of orange flowers yields, on the average, 2 grammes (30·86 grains) of *néroli*, worth from 500 to 1,000 francs per kilo (£9 1*s*. 7*d*. to £18 3*s*. 2*d*. per lb.). The orange-flower water is sold, on the average, at 25 centimes per litre (about 2½*d*. per quart). The leaves yield about 1½ grammes per kilo of *petit grain*, worth about one-tenth the price of the *néroli*. The quantity of flowers furnished by each tree varies considerably, and depends on age, vigour of growth, situation, soil and other circumstances. A well-kept garden near Grasse, with trees, half of which were forty years and the other half twenty-two years old, has produced as much as 2,800 kilogrammes (about 2 tons 15 cwt.) in a single year. The cost of planting a hectare of orange trees is estimated at 4,000 francs, or about £65 per acre.

HOME INDUSTRIES.

Lead Poisoning.—The reports on lead poisoning in the Potteries, to be found in the Annual Report of the Chief Inspector of Factories and Workshops just issued, are, on the whole, encouraging. Having regard to the comparative briskness of trade, the number of cases of lead poisoning in the year under review shows some little improvement. Mr. Shuter draws attention to the practical immunity of the jet and rocking branch from lead poisoning, which is remarkable when it is remembered that the glaze used at these works contains, as a rule, a larger percentage of lead than is the case in the general earthenware and china branches. In each case of lead poisoning a sample of glaze was collected and submitted for analysis, and it was found that the highest percentage of lead was 33·1, while the lowest was 11·2. It seems certain that on the whole greater care is being exercised by employers and employed, with a view to a more careful observance of the special rules so far as they affect this question. In some cases improvements are being effected in the lavatory accommodation, while in others new mess-rooms are being erected. Then some of the employers are anticipating the proposed new regulations, and are putting down impervious floors with facilities for flushing and draining; others, again, are having the walls of their dipping houses tiled, with the result that the places are lighter, cleaner, and much more free from dust. There is also a serious attempt on the part of some of the occupiers to use low solubility glazes. Some are using glazes that contain less than two per cent. soluble lead, while in one or two cases a leadless glaze is used to a great extent. Several of the firms have supplied their lead workers with pills known as anti-lead pills, and the men speak highly of their effect. Mr. Shuter says that the inspectors are satisfied that the best lines upon which to work with a view to fighting the evils of lead poisoning are: (1) efficient exhaust ventilation for the dust; (2) reasonable temperatures in which to work; and (3) scrupulous cleanliness on the part of the workers.

Women Workers and Childbirth.—Not much progress seems to be made in checking the industrial employment of women immediately before and after childbirth. As in former years, the majority of cases brought before the inspectors prove to be those which are untouched by the present law; in which means of support fail for the expectant or actual mother, and work and privation drive them hard at the time when, most of all, help is needed. A sad illustration is given by Miss Martindale, of a woman returning to work within a month after childbirth. The woman had five children under six years of age, three of whom could not walk. The woman's husband was a painter by trade, but had been out of work for seven months, and the woman was practically obliged to work up to the night of her confinement, and, although she was aware of the law, returned to work at the end of two weeks, in spite of being weak and unfit for work, rather than see her children starve. Miss Vines reports that the majority of the cases noted of mothers who have returned to work in the mills within a month of childbirth has again been found to be in Dundee. This place, with a population of 168,000 persons, is a town whose chief industry is carried on for the greater part by women, girls, and boys. The census figures of 1901 gave the total number of workers employed in the jute industry as over 37,000, and of those only 16 per cent. were males over twenty. In a recent month, of the eight cases investigated by a social settlement worker in Dundee, of mothers who had resumed work at the jute mills within a month of confinement, five out of the eight babies were found to be dead, two were alive, and one could not be traced. Of the eight, four were legitimate, four were illegitimate, and three out of the five deaths had been those of illegitimate children. The mother, eighteen years of age, of one of the living infants, was married about six weeks before the baby was born. After its birth her husband, aged twenty, deserted her, and threw up his job at the mill, saying it was too heavy. Possibly the number of deserted

wives and illegitimate births in Dundee, and the return of married women to the factory within a month of confinement, is connected with the fact that a married woman living with her husband is disqualified for the receipt of Poor Law relief, whereas the unmarried or deserted mother may, if destitute, be granted adequate medical attendance and maintenance, whatever her conduct or character, and can actually claim it as a legal right. The law would seem to put a premium on wife desertion.

Humidity.—Recently attention was directed in these Notes to the complaints of mill hands with regard to humidity in mills, and in the Factories Report the matter is referred to by Miss Squire and others. In her report, Miss Squire says that in Preston, in visits to thirty-four mills, the full limit of humidity allowed by law was found in seven cases, and excess in two. In Darwen, in visits to fifty mills, the full limit of humidity was found in seventeen cases, excess in three; on revisiting these mills, full limit was again found in eight and excess in one. Miss Lovibond was struck by the fact that whenever complaints were received from the weavers of discomfort or injury to health from the steam, there the shed is found to be one in which steaming to the full limit is the practice. The difficulty of obtaining a reading of the hygrometer before the conditions have been altered by the turning off of steam is great. The appearance of the inspector at the lodge is often the signal for the tackler to run and turn the steam off. By the time the inspector reaches the thermometer it gives the full limit, by the time the manager has been summoned to see the reading it has dropped below. In one of the mills in which excess of humidity beyond that allowed by law was found, the women were each in charge of twenty looms. The visit had been paid expressly to investigate a complaint that the women suffered from the strain of taking twenty looms each, the automatic Northrop loom being used in this mill. The strain must have been very great, and it was in these circumstances that women were working in an over-steamed atmosphere, the dry bulb being 76°, the wet 73°. In Darwen, Miss Lovibond reported that out of fifty-four humid sheds, ten only were provided with cloak-rooms. The terribly damp state in which she found shawls hanging on damp walls filled her, as well it might, with wonder that highly-organised workpeople have not yet secured for themselves such a necessity as a cloak-room.

Clerks and the Insurance Bill.—The directors of the Scottish Clerks' Association have addressed to the Government and to members of Parliament a letter in which they set forth in detail the various benefits which members of this registered society can subscribe for. "The benefits arranged by the Association," the directors proceed, "are, for a smaller subscription, largely in excess of those provided in the Bill, and are arranged in such a way as to be of the utmost advantage in meeting the special requirements of clerks. The whole position clearly demonstrates that, in dealing with such a class as clerks at least, there is ample justification for providing exceptional treatment under the Bill. It is respectfully suggested, however, that if any person can show, to the satisfaction of the Insurance Commissioners, that he is covered for the amount required under the Bill with any approved society, the management of which is on a satisfactory basis, and which is solvent, he should be granted exemption under section 2 of the Bill." Pointing out that the membership of the Association is now 6,500, the directors suggest that "if clerks are to be included, the number required for an approved society should be reduced." The directors draw attention to the Association's system with regard to medical treatment. The "moderate subscription includes payment of the members' own doctors' bills up to 4*s.* per visit, medicine, proportion of specialists' and operation fees, surgical and medical supplies, surgical fees applicable to dentistry, and medical fees and medicine supplied in sanatoria, hospitals, or nursing homes. The member is allowed to call in the nearest, best, or whatever doctor he chooses, without restriction. The scheme has worked well, and is exceedingly popular with members and doctors alike."

Discovery of Petroleum.—A petroleum spring has been discovered in the Coverage Pit of the Wigan Coal and Iron Company, Leigh. It may be remembered that in 1879, at the Mear Hay Collieries, Longton, Staffordshire, large quantities of oil were obtained under somewhat similar circumstances. The seam of coal from which it welled was nearly 500 yards below the surface. The Lancashire spring has been discovered at a rather greater depth, over 600 yards. The Mear Hay oil was rich in paraffin wax, which at that time was worth about 5*d.* per lb. as compared with the present price of under 2*d.* per lb. The yield was about three hundredweights per ton of oil refined. Some time afterwards, a similar spring was discovered in another colliery about a mile distant from Mear Hay, and was regularly refined until the pit was abandoned owing to the unremunerative character of the coal-seam. The oil was black in colour with a slight tinge of green. It had a sweet odour, and when brought to the surface set hard to a consistency like good yard. This was owing to the large proportion of wax in it. When refined, the oil was pure white, with a specific gravity of about ·895, and gave a fine white light. It is believed by many that the deposits of oil in the district, which has never been thoroughly prospected, are considerable.

The Seamen's Strike.—It is not thought likely that the sailors' strike which began last week will be very serious. It was intended to be international in character, but the foreign seamen have not responded, and it may be expected that before very long the local trouble in the United Kingdom

will have passed. The men seem to have been encouraged to strike by the way in which the Board of Trade has administered the language test, which has considerably reduced the number of seamen in the mercantile marine, but it may be doubted whether the reduction is sufficient to bring about the artificial scarcity necessary if the strike is to succeed. Probably there was no general desire on the part of the seamen to resort to a strike. They have their grievances, and some of them are pressing; but they are not likely to mend matters by refusing to work. The shipowners are too strong for them.

GENERAL NOTES.

THE PRODUCTION AND USES OF MONAZITE.—There is a constant demand for minerals carrying thorium for the manufacture of incandescent gas mantles. A large number of such minerals are known to the mineralogist, though only one, monazite, has been found in quantities large enough to supply the commercial demand. Two other minerals that carry a large percentage of thoria—thorite and thorianite—have been obtained in small quantities from Ceylon. The world's sources of supply of monazite for many years have been Brazil and the United States. The Brazilian output is shipped to Germany, Austria, and the United Kingdom for manufacture into thorium salts. The greater part of the monazite produced in the United States is used in that country, though certain quantities are exported annually. For a number of years past the supply has come from North and South Carolina, but it is probable that Idaho will add materially to the production hereafter. Deposits of monazite exist in other Western States and in Georgia and Virginia.

THE GROWTH OF THE LINER.—The past year has seen a remarkable development in the growth and dominance of the liner, a term not limited to mail and passenger carriers. 1910 saw the launch of the "Olympic," of 45,000 tons, that is now trading between Liverpool and New York; and it saw the "Mauretania" make the run from Liverpool and Fishguard to New York and back, after discharging mails, passengers, and cargo, and reloading cargo, mails, and passengers and 6,000 tons of coal, in just over twelve days. Nor is there any doubt that the triumphs of 1910 will be surpassed in the coming years. Already the Cunard Company has ordered a liner which will be 5,000 tons bigger and two knots swifter than the "Olympic," and the Germans are building a boat of over 50,000 tons. Cargo tramps of 10,000 tons are common, and a tonnage of 20,000 for this class of vessel is talked about. The deepening of ports and harbours has given a great impetus to the employment of these mammoth vessels, for the ton-mile cost of ocean carriage is reduced in proportion to the size of the carrier, if other conditions are suitable. Frequently the owner of the large liner is working at a profit when the owner of the old-type vessel is working at a loss. But it can hardly be said that the profits earned by the great fleets of liners are adequate to the capital invested and the risks incurred. In 1909, twenty-three of the passenger liner companies, with a paid-up capital of £21,211,360, and a debenture debt of £14,462,764, were only able to pay an average dividend of 4·10 per cent., and though they did slightly better last year they only paid 4·85 per cent.

LIBERIAN COFFEE.—The coffee-plant flourishes and reaches a size in Liberia to be found in no other part of the globe. The berries are larger and richer than those produced in any other country, and when properly cured possess the most delicious aromatic flavour. In Liberia two crops are gathered each year, one during the rains and the other during the dry season. The rains begin in April and May and close in October and November. The chief and most important coffee crop is gathered during the dry season, *i.e.*, in the months of December, January, and February. When the coffee is picked the berry is usually crushed in a mill or mortar, and then spread on the ground in the sun in a prepared place until well dried. Every evening the coffee is removed in order to avoid its getting wet from rain or dew. When dried it is beaten in a mortar until all the pulp is entirely separated from the beans. It is finally cleaned by fanning, and some of the planters grade it by removing all broken and undeveloped beans. Liberian coffee is very strong, and is therefore used in Europe to gives strength to weaker coffees. As generally prepared, it has a little bitterness in its flavour, and it is therefore often mixed with other coffees to overcome this.

RUBBER AND GUTTA-PERCHA IN BORNEO.—A great awakening took place in 1910 in regard to the value of the native gums of North Borneo, of which there are four—gutta-percha, gutta-jelatong, gutta-jangkar, and rubber. About the beginning of 1909 a British company obtained a concession from the Raja to control the output of the forests of Sarawak, and a large plant for refining and preparing the gums was erected at the mouth of the Sarawak River, eighteen miles from Kutching. It is estimated that no less than 40,000 acres have been brought under rubber cultivation in 1910 in British North Borneo. This has greatly stimulated the demand for coolie labour, which is brought from Java, Singapore, and Hong-Kong, through agencies at those places. According to Government reports, there are now employed on the various rubber estates about 15,000 coolies. When the trees now being planted become productive, it is estimated that 50,000 coolies will be required. As this estimate is based on real plantings, there is a bright outlook for large expansion in the general commercial condition of North Borneo.

ROYAL SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.

William Henry Davison, M.A. ....

Robert Kaye Gray ....

Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc. ....

Journal of the Royal Society of Arts.

No. 3,058. VOL. LIX.

FRIDAY, JUNE 30, 1911.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

ANNUAL GENERAL MEETING.

The one hundred and fifty-seventh Annual General Meeting for receiving the Report of the Council, and the Treasurers' Statement of Receipts and Payments during the past year, and also for the Election of Officers and New Members, was held in accordance with the By-laws on Wednesday last, June 28th, at 4 p.m., Sir John Cameron Lamb, C.B., C.M.G., Chairman of the Council, in the chair.

The Secretary read the notice convening the meeting, and the Minutes of the last Annual Meeting.

The following candidates were proposed, balloted for, and duly elected members of the Society :—

Ahsan-ullah, Khan Bahadur Moulvi, M.A., Nalta, District Khoolna, India.

Bartholomew, James, Blakesley Hall, Northants.

Bloor, Alfred J., Cove Lawn, Stonington, Connecticut, U.S.A.

Broderick, John Carroll, 151, St. James-street, Montreal, Canada.

Brush, Charles Francis, Ph.D., LL.D., 3725 Euclid Avenue, Cleveland, Ohio, U.S.A.

Connell, William F., 16, Court-street, Brooklyn, New York, U.S.A.

Craig, Eustace N., Messrs. D. & C. Rutter, Ltd., Crayford, Kent.

Crockatt, J. R., Lismore, Heathside-road, Woking.

Gray, Edward Dundas McQueen, M.A., Ph.D., Albuquerque, Bernalillo County, and Croftonhill Ranch, Eddy County, New Mexico, U.S.A.

Haq, K. F., Deputy Magistrate, Alipore, Calcutta, India.

Hirata, Tomoh, Consulate-General of Japan, 3, Alipore-lane, Calcutta, India.

Honey, William, Fequixquiapan, Queretaro, Mexico.

Hortvet, Julius, State Dairy and Food Department, Old Capitol, St. Paul, Minnesota, U.S.A.

Howison, Professor George Holmes, M.A., LL.D., 2631 Piedmont-avenue, Berkeley, California, U.S.A.

Humphrey, Professor Harry Baker, Pullman, Washington, U.S.A.

Jaffé, Israel, 24, Osnaburgh-street, N.W.

Keatinge, Sherbrooke Augustus John, M.I.Mech.E., Vineholt, Abbott-road, Lahore, India.

Khan, Raja Haji Saiyed Shaban Ali, Khan Bahadur, Salempur, District Lucknow, Oudh, India.

Lambert, Thomas Stoddart, J.P., 7, Arlington-street, Wellington, New Zealand.

Lindsay, David Colville, Paia Maui, Hawaiian Islands ; and Kingarth, Kirriemuir, Scotland.

MacAllister, Edward B., Rockland, Maine, U.S.A.

Macaulay, Magnus Johannes Oyedele, Blackhall-street, Waterloo, Sierra Leone, West Coast of Africa.

Mason, Miss G. Heather, The Meadow, Grosvenor-road, Reading, Berks.

Merk, William R. H., C.S.I., LL.D., Udimore, Ascot.

Myers, William S., 17, Madison-avenue, New York City, U.S.A.

Pan Wi Yan, 39, Heeren-street, Malacca, Straits Settlements.

Parsons, Hon. Sir Charles Algernon, K.C.B., LL.D., D.Sc., F.R.S., Holeyn Hall, Wylam-on-Tyne, Northumberland ; and 9, Hans Mansions, S.W.

Patiala, His Highness the Maharaja of, Patiala State, India ; and Addison Lodge, 7, Addison-road, W.

Ross, Alexander Carnegie, C.B., M.A., British Consulate, Buenos Aires, Argentine Republic, South America.

Ryerson, Colonel G. Sterling, C.A.M.S., 66, College-street, Toronto, Canada.

Singh, Sirdar Jogendra, Aira Estate, Kheri, India.

Smith, Ian Knighton, B.A., B.A.I., c/o The Chief Engineer, East Indian Railway, Calcutta, India ; and Portmerron House, Dungannon, co. Tyrone, Ireland.

Stovell, Captain Edwin Frederick, Keppel Harbour, Singapore, Straits Settlements.

Subhan, Nawabzada A. K. M. Abdus, Khan Bahadur, Senior Deputy-Magistrate and Collector, Furudpore, E.B.A., India.

Ullah, Muhammad Insha, Office of the *Watan*, Lahore, India.

The CHAIRMAN nominated Mr. G. E. Jones and Mr. H. B. Wheatley scrutineers, and declared the ballot open.

The SECRETARY then read the following—

REPORT OF COUNCIL.

I.—PRESIDENCY OF THE SOCIETY.

The first President of the Society was Lord Folkestone, who served from 1755 to 1761. He was succeeded by Lord Romney, who held office till 1794. In that year he was followed by the Duke of Norfolk, who remained President till 1816. In 1816 the Duke of Sussex was elected, and continued in office till his death in 1843, when the Prince Consort accepted the Presidency. He held the office till he died in 1861. Mr. William Tooke, an old and well-known member of the Society, was chosen to fill the office till the election of H.R.H. the Prince of Wales (King Edward VII.) in 1863. On King Edward's accession in January, 1901, the Presidency became vacant, and Sir Frederick Bramwell, one of the oldest and most distinguished members of the Council, was selected to fill it until H.R.H. the Prince of Wales (King George V.) on his return from abroad, accepted the office in December, 1901. His Majesty's accession again caused the Presidency to be vacated, and the Council nominated the Lord Chief Justice for election at the last General Meeting (June, 1910). Lord Alverstone held office till February last, when he reported to the Council that H.R.H. the Duke of Connaught had consented to accept the office of President, and His Royal Highness was elected by the Council for the remainder of the year. In accordance with the By-laws, the Council have now placed His Royal Highness's name on the balloting list for election as President.

His Royal Highness became a member of the Society in 1871, when he qualified as a life member by the payment of the usual contribution. In the following year (1872) he presided at the Technical Education Conference held by the Society, which started the movement in favour of Technical Education in London. The outcome of this conference was the establishment of the Technological Examinations, and its ultimate result the foundation of the City and Guilds of London Institute.

In 1902 His Royal Highness was nominated by King Edward as a Vice-President of the Society, and he has since been annually re-elected to that office.

II.—ORDINARY MEETINGS.

The Chairman of the Council, Sir John Lamb, chose for the subject of his opening address the association of telegraphy with the Society. This he succeeded in tracing back to 1805, when the silver medal was given for a night and day telegraph, of course of the semaphore order. It was in 1843 that the electrical telegraph came before the Society, for then Cooke and Wheatstone's apparatus was described and worked in the Society's meeting room. Sir John followed the history from that time down to the introduction of sixpenny telegrams, and was able to make out an excellent case, showing how much the Society had done, not only in publishing information, but in promoting the development of telegraphy by the various reforms and advances which from time to time it had urged on the Government of the day.

Besides the opening meeting, there were four Ordinary Meetings before Christmas. At the first of these Sir Henry Cunynghame described the very ingenious and useful device which, when applied to an ordinary safety lamp, renders the detection and quantitative estimation of minute quantities of fire-damp easy and certain. This apparatus has received the official approval of the Home Office, and a circular describing its use, and drawing attention to its value, has been issued by that department.

At the third Ordinary Meeting Mr. Campbell Ogilvie gave a very full and interesting account of the present condition of Argentina, its exports, imports, manufactures, and products. Sir Alexander Henderson, who has been for many years largely interested in British investments in the Republic, mentioned the fact that some hundreds of millions of British capital were now invested in the Argentine, and expressed the opinion that that amount would be doubled in the course of a very short period.

At the next meeting Dr. Vaughan Cornish, who had lately returned from a visit to Panama, gave an account of the recent progress in the construction of the canal, and described the great advances which had been made since the work had been taken in hand by the Government of the United States. Dr. Cornish had visited the canal two years previously, and had had opportunities of making a thorough examination of the works, so that he was in a position to give

the Society a very accurate account of their present condition and recent progress. When Dr. Cornish's paper is taken in conjunction with the paper read in January, 1907, by Monsieur P. Bunau-Varilla, written as it was from a very different point of view, it may be said that the records of the Society now contain very full information of the history and progress of this great work.

The last paper before Christmas dealt with an antiquarian subject, "A New View of Roman London," by Mr. Reginald Smith, of the British Museum. Mr. Smith is a recognised authority on the subject, and the value of the information which he has published in the "Victoria History of London" is generally admitted. Not very much is really known about Roman London; but it is certain that the investigations of Mr. Smith have added considerably to that knowledge.

At the first meeting after Christmas, Mr. J. C. Medd, who had already contributed valuable papers on "Education in the Netherlands" and "Agricultural Education" to the Society, described the work which is now being done in Holland by the Dutch labour colonies, and held up that work as a useful example for imitation in Great Britain. Lord Reay, who presided, from his own personal knowledge of the subject, was able to add a good deal to the information conveyed by Mr. Medd, whose views he thoroughly endorsed.

In his paper on "Motor Transport at Home and in the Colonies," Mr. Horace Wyatt dealt with the character of the motor vehicles required for ordinary rough work in new countries, with bad or undeveloped roads, and strongly advocated suitable motors as a method of opening up new and little-used trade routes.

At the first meeting in February, Mr. Philip J. Hartog, Academic Registrar to the University of London, read a very striking paper on "Examinations," and this was supplemented by an equally valuable communication from the chair by the Earl of Cromer. Both Mr. Hartog and his chairman dealt with the question of competitive examinations, and both were equally conscious of the many drawbacks of the competitive examination system, while it cannot be said that either of them was prepared to recommend a satisfactory substitute. Both the paper itself, and the remarks made by Lord Cromer, may be certainly commended to the attention of all who are interested in the subject.

At the following meeting, Captain Tremearne gave an interesting account, derived from personal experience, of the inhabitants of Northern Nigeria. This was followed by a paper by Mr. George A. Stephen, who was then Chief Assistant-Librarian at St. Pancras, on "Modern Machine Bookbinding." While the subject of artistic bookbinding in leather has been treated at great length in books and lectures, the manufacturing side of bookbinding has rather lacked attention. Mr. Stephen, who has devoted a great deal of attention to cloth bindings, and has produced an excellent book on the subject, dealt as fully with it as the limits of a paper permitted. He described the most modern methods, dwelt on their advances, and pointed out their deficiencies. The perfection with which books are now turned out, and their extreme cheapness, are certainly remarkable results of the application of modern machinery to an ancient and artistic industry.

The question of the presumed power of "dowsers," and the use of the divining-rod, is one that has for the most part been ignored by men of science. Professor Wertheimer, in his paper on "Waterfinders," gave the results of an attempt at a scientific investigation of a very old and very interesting subject. On the whole, it cannot be said that the believers in the divining-rod have had their faith shaken by modern researches, or that modern men of science have been the least moved from their attitude of incredulity.

It was in 1906 that Dr. (now Sir) Thomas Oliver gave the Society a paper on "Bridge Building by means of Caissons, including remarks upon Compressed-Air Illness." The subject was also dealt with by Dr. Scott Haldane in his lecture on "The Hygiene of Work in Compressed Air (Diving, Caisson Work, Sub-aqueous Tunnelling, etc.)," given under the Shaw Trust in November, 1907. At the first meeting in March, Dr. Leonard Hill, who has for many years been working at the subject, brought it up to date in his paper on "Caisson Sickness and Compressed Air." Much has been done in consequence of the investigations, to which Dr. Leonard Hill himself has contributed a very important part, in safeguarding the health of those who work in compressed air, and in lessening the dangers attendant on the conditions under which they work.

At the next meeting, Dr. James Cantlie gave a useful popular account of the methods by which plague is spread, and of the means which ought to be taken to lessen the danger of its dissemination. The manner in which plague is communicated by means of rats and their

parasites is now thoroughly well known, and this knowledge ought in course of time to provide, and it may reasonably be expected will provide, a means for ultimate extinction of the epidemic.

A great deal of attention has lately been drawn to the adulteration of food, and many exaggerated statements about food adulteration have been put forward. A useful account of the facts of the case was given to the Society by Colonel Charles E. Cassal, Public Analyst of the Borough of Kensington. The meeting had the advantage of being presided over by the Lord Mayor of London (Sir Thomas Vezey Strong), who made some very valuable practical remarks as to the action which ought to be taken to ensure the purity of all food products.

At the next meeting, Mr. Arthur Davis gave a thoroughly practical account of "The Manufacture of Portland Cement," which will be found of special interest in view of the increased scope and importance of the applications of this material. At the last meeting in March, Mr. George Heming gave an interesting discourse on "Art Education" as applied to the work of the jeweller and goldsmith. Mr. Heming's paper to a large extent dealt with the useful work which is being carried on by the Goldsmiths', Silversmiths', and Jewellers' Art Council, and laid much stress on the importance of raising the standard of work by the education of the handicraftsmen and the discouragement of the use of machinery.

Mr. Henry L. Heathcote's paper on "Wheels, Ancient and Modern" covered a wide subject, and showed what a remarkable development has taken place, and how much progress has been made in the growth from the elementary disc of wood, which served as a wheel, to the scientifically-constructed piece of mechanism which is now employed for bicycles and for motors.

The paper read at the next meeting, by Mr. Noel Heaton, on "The Production and Identification of Artificial Gems," was of extreme interest. Probably not many persons are aware that rubies and certain other precious stones can now be actually manufactured, that is to say, that rubies, not merely imitations, such as for long have been in use, but identical in chemical composition and in other characteristics with the natural stones, can be produced as an article of commerce. The manufactured stone can indeed be identified by certain peculiarities consequent on the nature of its crystallisation: in fact, it would not be too much to say that the artificial stone is a little more perfect than the natural one, which has certain characteristics, or indeed defects, which enable the two to be distinguished. Mr. Heaton's description of the whole process of manufacture was extremely clear and full, and the paper was specially valuable as a record of the success which has now been attained in the process of manufacture.

The question of London transport has been before the Society in various forms, notably in the two addresses delivered by Sir John Wolfe-Barry in 1898 and 1899, when he was Chairman of the Council, and in the paper read here by Captain Swinton in 1906. Mr. A. W. Gattie approached the subject from a different standpoint, and described a scheme which he has worked out for the distribution of goods of every character (with the exception of cattle and coals), by means of a Clearing House similar in principle to the Clearing House first employed by bankers, and afterwards by railway companies, for dealing with cheques and with railway traffic. Mr. Gattie's scheme is a large and comprehensive one. It was put forward very clearly in his paper, and the discussion upon it helped still further to bring out the various points involved.

In 1905 Mr. Sigmund Stein read a paper here on "The Manufacture of Sugar from British-grown Beet." Mr. Hal Williams, in his paper on "Beet-Sugar Factories," did not attempt to discuss the whole problem, but merely described the mechanical arrangements which had been found serviceable in other countries for the manufacture of sugar from beet. It was a valuable contribution to an important controversy, and the information contained in it will be of considerable value to those who are now endeavouring to create this important industry in England, if, as may be hoped will be the case, they succeed in establishing, at all events, an experimental factory.

The last two meetings of the session were notable, because in both cases the papers were read by distinguished foreigners. On May 17th, Professor Raoul Pictet came over from Berlin to read a paper on "Low Temperatures," and on May 24th Mr. Frank M. Andrews came specially from America to read his paper on "American Architecture." Professor Pictet has attained a world-wide reputation as one of the first to succeed in liquefying certain of the so-called permanent gases—those gases, that is to say, which had been unliquefied in the earlier experiments of Faraday. This was as far back

as 1878. Since that time Professor Pictet has been working steadily at the subject, and though other physicists, notably Sir James Dewar, have carried still further the investigations in which he was the pioneer, he has always continued his original work, and has done much to advance our knowledge of the subject. In his paper he gave a very full account of his researches, and of the speculations which he had founded upon them. His principal results were obtained in connection with the effect of low temperatures upon chemical reactions. By continuous experiments he was enabled to ascertain the precise temperature at which any special reaction ceased to occur, and in his opinion it was possible by varying the temperatures to control, and, to some extent, to vary the nature of the reaction itself. Passing on from chemistry, he discussed the application of thermodynamics to physics, and even to biology, and it may be taken for granted that the speculations which he initiated will afford ample material for future discussion and consideration.

Mr. Andrews' paper on "American Architecture" dealt specially with the treatment to which American architecture has been subjected —the production of enormous buildings occupying a limited ground area. It appears certain that this style of architecture was initiated by the fact that New York, cramped within the narrow limits of Manhattan Island, and unable to extend laterally, found it only possible to extend vertically, and her architects were therefore compelled to consider methods of accommodating the greatest possible amount of buildings on the very smallest amount of space. From this standpoint Mr. Andrews traced the growth of a genuine style of American architecture, and claimed for his country that it was now doing what the older civilisations had failed to do, namely, to develop an individual style of architecture for itself. The interest of the paper was augmented by a very fine collection of lantern-slides of American buildings of every sort.

III.—Indian Section.

The papers read in the Indian Section numbered, as usual, six.

The series of descriptive papers on the various Presidencies and Provinces that was instituted ten years ago continues to be appreciated. In the case of a huge country, or rather congeries of countries, so complex as India, a method of detailed treatment has necessarily many advantages, and these ably-written papers seem specially calculated to promote that better understanding of our great Dependency which the Section, since its establishment, more than forty years ago, has always kept in view. The first of the papers referred to related to Madras, one of the largest and oldest of the British settlements; the latest, read on May 25th, by Mr. W. R. H. Merk, dealt with the North-West Frontier Province, the smallest and one of the youngest of the Provinces, indeed the youngest of all if Eastern Bengal be excepted. Unlike any other administrative unit in the Indian Empire, the Province described by Mr. Merk, its late Chief Commissioner, comprises two totally distinct and dissimilar forms of jurisdiction. Only a third of the area, or some 13,000 square miles, is under full British law and administration; the remainder is occupied by warlike tribes, who, although under complete British "political control," have been permitted to retain their independence so far as internal and municipal affairs are concerned. The one thing, from a political point of view, to which the border tribesmen are passionately attached and for which they will fight to the end, is their domestic or municipal freedom. In the adoption of the dual system lies, in Mr. Merk's judgment, the solution of the problem of the borderland. Since 1901, when the Province was called into existence by the then Viceroy, Lord Curzon, there have been only two military expeditions, "each of the shortest duration—'week-end wars.'" In the previous sixty years there were fifty-six frontier campaigns. Significant though these figures appear to be, Mr. Merk observes that too much reliance cannot be placed upon them, since, owing to the recent arming of the tribes, "we may have, at any moment, to reassert our strength." On the other hand, many indications of a change for the better are seen. One of several striking instances mentioned in the paper is that of the Kohat Pass. At either end of the Pass lie the important garrisons and civil headquarters of Peshawar and Kohat. Many attempts to construct a much-needed metalled road were baffled by the tribesmen, who thought that if the road came their internal independence would go. More recently the case was put to them again. An officer in whom they trusted—and Mr. Merk tells us that the Pathans are specially susceptible to personal influence—succeeded in convincing them that their fears were groundless; they accepted the road, assisted to construct it, and "where formerly one had to pick one's way on horseback over the boulders of a torrent bed,

one motors now in a couple of hours from Peshawar to Kohat."

The mineral resources of India, to the importance of which attention was called in a paper read before the Section as far back as 1873, have been adequately described in official publications issued during Sir Thomas Holland's term of office as head of the Geological Survey (1903–9). The comprehensive and valuable paper—"The Trend of Mineral Development in India"—which the late Director of the Geological Survey read on April 27th, consisted of an exhaustive examination of all the facts essential for a fair discussion of the political lessons to be derived from recent experience. The rules adopted under Sir Thomas Holland's directorship removed most of the undesirable restrictions then in force, and further relaxations are now under consideration. These, it is hoped, will meet complaints as to delays in disposing of applications for concessions—delays largely due to excessive caution on the part of district officers in interpreting the regulations, and not to sheer wilfulness. Sir Thomas Holland suggests caution in the export of the country's inorganic products, or some of them, and urges that the time is coming when the mineral question will be to India, in its geographically isolated position, one of the greatest of its political questions. Not remotely connected with the signs of a great industrial awakening in India, is the subject which was brought forward by Mr. Reginald Murray in his able paper on "Banking in India." He contrasted the conditions of trade finance, prior to the introduction of joint-stock banking, with the present state of things, and demonstrated the necessity for an extension of the machinery for attracting and distributing capital to meet the increasing wants of the country. Though there are indications of vigorous growth, banking in India a hundred years after the first joint-stock bank was established is, he maintains, at present in its swaddling-clothes. The paper also inquired into the causes which have contributed "to set-back India's credit in the City of London," and it was contended that India as a field for the profitable and secure employment of sterling capital offers much greater opportunities than have been recognised hitherto by the London market. The chairman of the meeting, Sir Felix Schuster, in a weighty speech, differed to some extent from Mr. Murray's conclusions as to the supposed "set-back." In common with other "gilt-edged" securities, and for similar causes, the price of Indian stock has fallen, but not, Sir Felix Schuster declares, proportionately more than that of British Consols. Given a period of rest and freedom from political agitation, both in India and at home, this eminent financial authority feels confident that, with the development of the railways, with the benefits bestowed by irrigation, with the care of the Government for the well-being of all classes, the commercial development and prosperity of the country in the next ten to twenty years will be such as are almost undreamed of at the present time.

In his admirable paper on "Education in India," Mr. Claude H. A. Hill dealt with one particular feature of the problem of Indian education—religious or moral training. After sketching the history of the connection of the Government with the promotion of education, and of the direction in which their ideas respecting moral instruction were moulded, he explained the attitude of the Indian mind towards education and religion, and argued in favour of a reconsideration of our policy of rigid secularisation. Finally, he offered suggestions as to the methods by which the change he advocates may be effected with the least difficulty and risk. Favourable reference was made both in the paper and in the discussion to the work in regard to India which is being quietly done by the Moral Education League.

Mr. Robert F. Chisholm, in his very interesting illustrated paper on the Taj Mahal, endeavoured to show that the secret of the charm of this famous monument lies in the adaptation by its unknown designer of "a studied and systematic system of heightening the deep shadows and avoiding all those black patches which destroy a sense of distance."

Mr. R. A. Leslie Moore, in his excellent and non-critical paper on "Indian Superstitions," related and commented upon a very large number of curious domestic beliefs prevalent in India, particularly that part of India with which he is most acquainted, the Presidency of Bombay. Popular beliefs of this character vary in different parts of the Peninsula, and Mr. Moore's examples were supplemented by speakers with experience of Bengal, Madras, the United Provinces and the Punjab.

IV.—Colonial Section.

The session opened on November 29th with what may be called an official paper on "The Progress and Prospects of Mining in Western Australia." Its author, Mr. A. Montgomery, M.A., F.G.S., is the principal adviser on mining

affairs to the Government of Western Australia, and at the outset of his elaborate paper he acknowledged the indebtedness of that State and of himself to the Society for affording him an opportunity, during his visit to England, of addressing an audience in the heart of the Empire on one of the leading industries of so distant a member of the Imperial body. *Inter alia*, he discussed the causes of the hostility that for some years has prevailed in the London market towards Western Australian mining ventures. One of these causes is the failure of so many companies in the earlier days of the goldfields. Various criticisms of the mining policy of the Government were answered, and, finally, attention was called to the "exceptionally good opportunities offered by Western Australia to capital for legitimate mining operations, and also to men who have to depend on their own physical efforts to make their living for doing so either in mining or in farming pursuits." The late Governor of the State (Admiral Sir Frederick Bedford) and the Agent-General for Tasmania (the Hon. Sir John McCall, M.D.) were among those who took part in the discussion.

"The Tin Resources of the Empire" was the title of a very able paper read on January 31st by Mr. F. Douglas Osborne, M.Inst.M.M. Mr. Osborne occupies in the Federated Malay States a position similar to that filled by Mr. Montgomery in Western Australia, and therefore he spoke from personal knowledge of the principal source of the tin supply. Out of a total production of 104,250 tons in 1910, the contribution of the British Empire was 72,450 tons, the share of the Straits Settlements amounting to 58,500 tons. Although the paper was largely devoted to the Malay Peninsula, the other tin-fields, including the famous workings in our own country, were surveyed as far as the available data permitted. With regard to Cornwall, it was pointed out that the annual output has fallen from 14,000 tons to an average of 4,800 tons, and no prospect of an improvement was held out by Mr. Osborne. On the other hand, Mr. J. H. Collins, and the other representatives of the western Duchy who spoke, maintained that the present condition of the industry is due merely to temporary causes, and that when these are removed the Cornish mines will be almost as remunerative as ever they were. Mr. Osborne's paper is one of the series recently begun in the Colonial Section, with the object of dealing separately with the more important commercial products of the Empire.

The Secretary of State for the Colonies, the Right Hon. Lewis Harcourt, M.P., presided at the next meeting (February 28th), when the Hon. Sir Richard Solomon addressed the Society on "The Resources and Problems of the Union of South Africa." While the history of the material progress of South Africa since the first discovery of gold, forty years ago, has been substantially a history of mineral development, the High Commissioner thinks that an era of great agricultural prosperity has now commenced, and he predicts that before many years have elapsed the Union, in addition to being a rich mineral country, will be "one of the principal agricultural countries of the world." In his lucid and statesmanlike utterances on the problems confronting the Union, he took a hopeful view of the future relations of the English and the Dutch inhabitants. "The fact that the children of both races now attend the same schools and grow up together will make the next generation of men and women free from racial feeling." As to the most serious of all the problems—the Native Question—he submitted that no man living to-day can forecast its ultimate solution. A sound native policy must be slowly and naturally developed, and in that development the only course in his opinion is to "adhere to the good sound principle of justice and toleration." The discussion was opened by the Right Hon. Sir Walter Hely-Hutchinson who, in an eloquent speech, associated himself with all Sir Richard Solomon said regarding the future of the two white races in South Africa. The other speakers were the Duke of Argyll, Lord Blyth, Chairman of the Colonial Section, who recently visited South Africa at the request of the late Government of the Cape Colony to report to them on the prospects of the viticultural industry, Sir David Gill, and Mr. P. J. Hannon.

On April 4th Captain R. Muirhead Collins, R.N., C.M.G., read before a large and distinguished audience a very useful paper on "The Commonwealth of Australia." The world, he declared, has no parallel for the changes that have been brought about in that Continent since the federation of the six States—New South Wales, Queensland, South Australia, Tasmania, Victoria, and Western Australia—eleven years ago. In short, Australia is embarking on a new era in Local and Imperial politics, in Primary and Secondary Industries, in Defence, and in her relations to the outside world. The importance

of the occasion was enhanced by the presence in the chair of Lord Denman, as this happened to be his lordship's earliest appearance at a public gathering since the announcement of his appointment as Governor-General of the Commonwealth.

At the concluding meeting, held under the presidency of the Duke of Argyll on May 9th, Mr. F. Williams Taylor read a most interesting paper on "Canada and Canadian Banking." He began by sketching the great Dominion province by province. He then described its excellent banking system, largely the handiwork, as he pointed out, of Scottish settlers, and showed how much that system has assisted in the wonderful commercial development of the country. To meet the financial requirements of the Dominion, there are altogether twenty-nine banks, with 2,500 branches, the paid-up capital and reserve being £28,000,000. The discussion on Mr. Williams Taylor's paper was one of the best of the session, the speakers including, besides the Duke of Argyll, those veteran Canadian statesmen, Lord Strathcona and Sir Charles Tupper, as well as Sir Felix Schuster and the American Consul-General (the Hon. J. L. Griffiths).

V.—Cantor Lectures.

There were five courses of Cantor lectures given during the past session, and the subjects dealt with were as varied as usual. Three of them were distinctly technical, namely, the courses by Mr. Darling, Professor Brown, and Professor Fleming.

In his course on "Industrial Pyrometry," Mr. C. R. Darling gave a very full and clear account of the whole subject, including its history from the earliest attempts to measure high temperatures and the first crude pyrometer of Wedgwood down to the development of the very beautiful and accurate instruments which enable modern manufacturers to measure with certitude the precise degrees of temperature required for the manufacture of pottery, glass, iron and steel, and for other processes in which extremely high temperatures are required. It is a point which may be noted with some interest that it is almost true to say that during very recent times the thermometric scale has been enlarged from a range extending merely from the solidification to the vaporisation of water, to one reading from the absolute zero of temperature (−273° C.) up to, say, 1500° C.; that is to say, a scale of 100° Centigrade, from 0° to 100°, has been enlarged to a scale of nearly 2000°, from −273° C. to +1500° C. or thereabouts. It is not of course meant to suggest that temperatures below 0° and above 100° were not recognised when the first thermometer was constructed, but only that the accurate measurement of temperatures much outside the scale was impossible.

Professor Adrian Brown's course on "Brewing" may be said to have dealt with the chemistry of that subject as it has advanced from the admirable course of lectures given by Dr. Graham thirty-seven years ago, in 1873–4. One of the points on which Professor Brown laid special stress was the character of the barley which was required by the brewer. He described the present position of knowledge regarding the characteristics of malting barley, and gave the results of recent experiments in barley cultivation in Ireland and elsewhere. He showed that it was now pretty well known what the characteristics required were, and how they could be obtained, so that it remained for farmers to produce the grain best suited for the purposes of the brewer.

Professor John Fleming has already given three courses of Cantor lectures to the Society on electrical subjects. The course this session was on "Applications of Electric Heating." He described and discussed the laws of electric heating, the appliances and processes involved, the application of electric heating to industrial purposes, and finally domestic applications of electric heating. In respect of the latter, the advantages for many purposes are very great; but, at all events, as regards London, until electrical energy can be obtained at a lower rate than that at which it is at present provided, the use of electricity for such purposes as cooking and the warming of rooms must remain a somewhat costly luxury.

Of the other two courses of Cantor lectures, one was artistic, that in which Mr. Frederick Wedmore dealt with "Etching." Two lectures were devoted to the subject—one dealing with the "Old Masters" and the second with "Modern Etching." Both were extremely interesting, and were much appreciated by a numerous audience.

The last course this session was of a more purely scientific nature than its predecessors. Dr. Alfred Tutton devoted four lectures to a description of the structure of "Rock Crystal," and its practical applications. The whole subject of crystallisation and crystallography is an extremely complex one, but it was very clearly dealt with by Dr. Tutton, who availed himself to the full of the opportunities for

experimental illustration offered by the projecting polariscope. Perhaps no more beautiful illustrations can be offered to an audience than those which are provided by the suitable application of polarised light. Dr. Tutton was also able to exhibit to his audience a selection from the magnificent collection of objects constructed from rock crystal in the possession of Mr. Alfred Simson, a member of the Society, who very kindly lent some of his finest specimens for the purpose. In the last lecture an interesting collection of chemical and other apparatus made of fused silica was also exhibited.

VI.—Juvenile Lectures.

There are perhaps few more wonderful applications of photography to scientific research than its application to the study of drops and splashes. No one has carried this research so far as Professor Arthur Worthington, and the audience which came to the Juvenile Lectures last Christmas were fortunate in getting a full exposition of this very remarkable scientific application of photography from the acknowledged master of the subject. Professor Worthington not only showed the long series of marvellous photographs which he has secured, each of them taken with an exposure of about two-thousandths of a second, but exhibited the apparatus which he used, including the ingenious device for regulating the precise instant of illumination by the electric spark at the various stages of the fall of the drop, or the production of the splash.

VII.—Albert Medal.

The Council of the Society, with the approval of His Royal Highness the President, have awarded the Albert Medal of the Society for the current year to the Hon. Sir Charles A. Parsons, K.C.B., LL.D., D.Sc., F.R.S., for his experimental researches into the laws governing the efficient action of steam in engines of the turbine type; and for his invention of the re-action type of steam turbine and its practical applications to the generation of electricity, the ventilation of mines, blast-furnace work, ship propulsion, and other important purposes. The beneficial results which have followed upon these inventions include a cheapening of the production of mechanical power, greater economy and speed for steamships, and the first successful solution of the problem of rotary engines which long had baffled many other inventors.

The problem of design for rotary engines had long engaged attention, and the idea of utilising the flow of steam and its impulse in producing rotary motion had been applied in various forms by a great number of inventors. Sir Charles Parsons, before completing his course of study at the University of Cambridge, had begun to work on this subject, and had designed an epicycloidal engine, of which several examples were made and set to work. Subsequently he undertook a long series of experimental researches into the action of steam-jets, and the methods of utilising the energy possessed by such jets, finally reaching the conclusion that the best results would be obtained by splitting up the fall in pressure in the steam over a great number of wheels or turbines in series rather than in following the impulse-principle, which had previously been generally favoured. Sir Charles began the construction of these reaction turbines in 1884, the first applications being for the purpose of electrical generation. About ten years later he undertook the construction of the first turbine-propelled steam vessel, the "Turbinia." The result of his continuous work, extending over the last twenty-seven years, has been a practical revolution in steam machinery both on land and on sea. Very great economies have been obtained in the production of mechanical power and in the cost of upkeep of steam engines. The cost of electrical energy has been reduced. The efficiency and speed of steamships has been greatly enhanced, and results have been obtained which would have been impossible with the best engines of the reciprocating type. The importance of the discoveries made by Sir Charles Parsons has been recognised and utilised throughout the world, and the rapidity and extent of the applications of the new type of engine have far surpassed any corresponding change in the history of mechanical invention.

VIII.—Medals.

The Council have awarded the Society's Silver Medal to the following readers of papers during the Session 1910–11.

At the Ordinary Meetings.

Campbell P. Ogilvie, "Argentina from a British Point of View."

Vaughan Cornish, D.Sc., F.G.S., F.C.S., "The Panama Canal in 1910."

Reginald A. Smith, B.A., F.S.A., "A New View of Roman London."

Philip Joseph Hartog, M.A., B.Sc., "Examinations and their Bearing on National Efficiency."

George A. Stephen, "Modern Machine Bookbinding."

Dr. Leonard Hill, F.R.S., "Caisson Sickness and Compressed Air."

James Cantlie, M.A., M.B., C.M., F.R.C.S., D.P.H., "Plague and its Spread."

George B. Heming, "Art Education in the Jewelry, Goldsmithing and Allied Trades."

Professor Raoul Pictet, "Les Basses Températures."

Frank M. Andrews, "Architecture in America."

In the Indian Section.

Robert Fellowes Chisholm, F.R.I.B.A., F.S.A., "The Taj Mahal and its Relation to Indian Architecture."

Reginald Murray, "Banking in India."

Claude Hamilton Archer Hill, I.C.S., C.S.I., C.I.E., "Education in India."

Sir Thomas Henry Holland, K.C.I.E., D.Sc., F.R.S., "The Trend of Mineral Development in India."

W. R. H. Merk, C.S.I., LL.D., "The North-West Frontier Province of India."

In the Colonial Section.

A. Montgomery, M.A., F.G.S., "The Progress and Prospects of Mining in Western Australia."

F. Douglas Osborne, M.Inst.M.M., "The Tin Resources of the Empire."

Captain R. Muirhead Collins, R.N., C.M.G., "The Commonwealth of Australia."

F. Williams Taylor, "Canada and Canadian Banking."

Of recent years it has been the practice that no medals should be awarded to readers of papers who had previously received medals from the Society. Acting on this rule the Council were precluded from considering the papers by Mr. John C. Medd, M.A., on "The Dutch Labour Colonies," and by Mr. Noel Heaton, B.Sc., on "The Production and Identification of Artificial Gems." The Council, however, desire to express their high appreciation of these papers by thanking their authors for them.

The Council have always felt themselves precluded from awarding medals to members of their own body, and they, therefore, could not offer one to Sir Henry H. Cunynghame, K.C.B., for his paper on "Methods of Detecting Fire-Damp in Mines," or to the Hon. Sir Richard Solomon, K.C.B., for his paper on "The Resources and Problems of the Union of South Africa." They had, however, much pleasure in recording their sense of the value of these papers by passing a special vote of thanks to their authors.

IX.—Fothergill Prize.

In former Reports of the Council, the conditions have been set forth under which a gold medal, or a prize of £20, was offered for rescue apparatus for use in mines. The prize was offered for the best portable apparatus or appliance for enabling men to undertake rescue work in mines or other places where the air is noxious, the object being to encourage the production of a rescue apparatus which would enable a succouring party to reach men cut off —in case of mining accidents—by irrespirable gases, or overcome by them. It was known that many such appliances existed, but it appeared uncertain which of them were the best, or even which were of practical use.

The report of the Committee appointed by the Council to consider the apparatus submitted appeared in the *Journal* of the 16th inst., and it is only necessary to record here that, in accordance with the recommendations of that report, the Council have awarded the following prizes:—

A gold medal to Mr. H. A. Fleuss, for the apparatus submitted by Messrs. Siebe, Gorman & Co.

A gold medal to Mr. W. E. Garforth, in recognition of his efforts to perfect and to secure the adoption of rescue apparatus in mines.

A silver medal for the "Draeger" apparatus submitted by Mr. Richard Jacobson.

A silver medal for the "Meco" apparatus submitted by the Mining Engineering Company.

The Council trust that the awards may encourage the recipients to persevere in their efforts to produce a thoroughly trustworthy apparatus, the need for which is constantly becoming more and more evident. In the meantime, they are satisfied that any one of the four systems commended by the Committee is capable of rendering very valuable aid in cases of accident, and they trust that one or other of them will be adopted without delay by colliery owners throughout the country.

X.—Owen Jones Prizes.

After the death, in 1874, of Owen Jones, the well-known decorator and writer on decoration, a committee was formed to collect subscriptions for the purpose of founding a memorial, and the balance (a sum of £400) was presented to the Council of the Society of Arts upon condition of their expending the interest thereof in prizes to "Students of the Schools of Art who, in actual competition, produce the best designs for Household Furniture, Carpets, Wall-papers

and Hangings, Damask, Chintzes, etc., regulated by the principles laid down by Owen Jones." The prizes have now been awarded annually since the year 1878 on the results of the annual competition of the Science and Art Department, and its successor, the Board of Education.

Six prizes were awarded last session (1909–10), each prize consisting, in accordance with the regulations prescribed for the administration of the Trust, of a bound copy of Owen Jones's "Principles of Design," and a bronze medal.

Four hundred and forty-one works from 164 competitors were considered by the Examiners. In the previous year, 192 competitors submitted 481 works for competition.

In their report for 1910 the Examiners state: "Among the 441 works sent in for this competition were a number of designs without any merit whatever; some were so bad as to be unfit for submission in any competition, a considerable number of these coming from one school. The most successful attempts were found among the Woven, Printed, and Stencilled Fabrics. The Designs for Furniture were not thoughtfully considered from the point of view of the principles laid down by Owen Jones. There were some promising specimens of Tiles, Plaster work, and Embroidery."

The list of the successful candidates has already appeared in the *Journal*.*

The *Journal* of January 20th, 1911, contained an interesting analysis of the results of the competition, showing the various successes of the Schools of Art whose students had taken prizes. In all, the Macclesfield School of Art obtained 33 awards; the Manchester Cavendish Street School, 30; Glasgow, 24; Nottingham, 14; and the various London schools, 30. Twenty-eight other schools gained among them 64 awards.

XI.—North London Exhibition Trust.

For some years past the interest on the sum of £157, the surplus of the North London Exhibition held in 1864, has been devoted to the award of prizes to students of the Artistic Crafts Department in the Northampton Polytechnic Institute, Clerkenwell. At present an annual sum of £5 is placed at the disposal of the Governors of the Institute. Of this amount £4 has been expended. The prizes for the present year are to be awarded as follows:—

First Prize of £3, William Ingleton, for a tea service in copper, consisting of teapot, cream jug, and sugar basin.

Second Prize of £1, Henry William North, for a specimen of bookbinding (finishing).

The awards have been made on the recommendation of Mr. Alan S. Cole, C.B. In previous years the works were always adjudicated upon by the late Mr. Lewis Foreman Day.

XII.—Examinations.

As in recent years, it is proposed to postpone any detailed report on the year's examinations until the results have all been issued. The results of Stage III. (Advanced) have just been issued. Those of Stage II. (Intermediate) will be published in July; and those of Stage I. (Elementary) in August.

The total number of papers worked was 34,260, the number last year being 30,852, an increase of 3,408. These were divided among the various Stages as follows:—Stage I., 14,302; Stage II., 14,026; Stage III., 5,932. The corresponding figures for 1910 were:—Stage I., 12,720; Stage II., 12,847; Stage III., 5,285.

A painful incident connected with the examinations was the prosecution of two teachers for fraudulently obtaining prizes at the Society's examinations. The Council were released from the duty of carrying on the prosecution itself by the action of the Public Prosecutor, who considered the question of sufficient public importance to justify his undertaking the prosecution. The Council feel that the Society is much indebted to him for his action, as it was far more satisfactory that the duty should be undertaken by the proper public official rather than by the Society itself. A full report of the proceedings has already appeared in the *Journal*. The only comment to be made upon them is that it is earnestly hoped that the example made will deter others from attempting similar frauds.

It is obvious that the system of the Society's examinations—a system which has been adopted by all the other public examining bodies—lends itself quite easily to fraud, if the members of the Local Committees and the Superintendents of the examinations, upon whom the Society is bound to rely for the satisfactory discharge of their duties, betray their trust. One principal element of value in the Society's system is the low cost of the examinations. Its examinations are appreciated by, and are serviceable to, a very large number of persons of a class quite unable to pay high fees, and the fees, varying as they do from 2*s.* 6*d.* to 1*s.*, are kept down to the very lowest point consistent with the efficient

* See *Journal*, Vol. LVIII., p. 779, July 15th, 1910.

carrying out of the system. The funds at the disposal of the Society are not sufficient to permit any considerable expenditure, and without such expenditure it is impossible to introduce many improvements which might be effected, if so strict an economy were not necessary.

Failing paid assistance, the Society is forced to rely, as it has done for more than half a century, upon voluntary aid, and in almost every case it has been found that such aid is efficient and trustworthy. But the development and competition between the various proprietary institutions which have sprung up of late years, and which it may be added are doing very efficient service in the cause of education, has produced a source of temptation amongst those interested in such institutions, who are anxious to obtain all possible credit for their own schools, and may occasionally be led away to attempt to obtain such credit by illegitimate means. The inducements to such a course of conduct are very small, the prizes are of a trifling amount, and practically neither they nor the certificates are of much value to those who gain them by improper means, except for the swelling of the list of successes of their schools. Sooner or later detection is inevitable, because such fraudulent proceedings cannot be carried out without its becoming the common knowledge of the students and others connected with the establishment that they are going on, and, as in the case which has caused so much annoyance and trouble to those connected with the Society's examinations, attention is drawn to the matter by some unsuccessful candidate or teacher. The Council are now considering very carefully the possibility of devising further checks on dishonest candidates or teachers, but they are satisfied that such dishonesty is very rare, and on the whole they believe that they may still rely on the co-operation of those for whose benefit the whole system is carried on, for the preservation of its genuine character.

XIII.—Practical Examinations in Music, 1910.

The Practical Examinations in Music were not concluded last year until July 2nd, too late for the results to be included in the Report of the Council. They lasted for nine days.

The examinations were conducted by Dr. Ernest Walker, M.A., and Mr. Burnham Horner.

The system of examination was the same as that for recent years. For instrumental music certain standards are given, and candidates are asked to select for themselves which of these standards they choose to be examined in. The standards range from easy to very difficult music. For each standard a list of music is given for study, and from this list candidates select the pieces they will sing or play. Candidates are expected to play or sing the pieces which they have prepared, to play or sing a piece, or portion of a piece, at sight, and to play certain scales.

In all, 351 candidates entered, and of these 339 were examined, a decrease of 53 as compared with last year. There were 268 passes and 71 failures.

The following were the subjects taken up:—Piano, singing, violin, violoncello, clarinet, and viola; 264 entered for the piano, 204 of whom passed; 64 entered for the violin, of whom 56 passed; 1 entered and passed for the violoncello; 8 entered for singing, of whom 5 passed; 1 entered and passed for the clarinet, and 1 for the viola. Two medals were awarded.

The Examiners reported that the quality of the work was about the same as in recent years. There were not a few candidates who gave evidence of talent and good training; others, however, had received only slight preparation. Many pianists, who played the mere notes quite accurately, lost ground through deficiencies of touch and of general technical polish, to the cultivation of which teachers might with advantage pay special attention. Candidates were also warned against attempting music too difficult for their present attainments.

XIV.—Practical Examinations in Music, 1911.

The Practical Examinations for the present year have not yet been held. They will commence on July 1st, and will be finished on July 10th, after which a summary of the results will be given in the *Journal*. The work of the examination is being carried out by the same examiners as in the last eight years; 289 candidates have entered for the present examinations, a decrease on last year of 62.

XV.—Viva Voce Examinations in Modern Languages.

Up to the present date sixteen examinations have been held this year in London, Birmingham, Guernsey, Liverpool, and Manchester. Arrangements have also been made for holding examinations at several other centres.

At these examinations 369 candidates presented themselves, of whom 290 passed (ninety with distinction) and seventy-nine failed. The languages taken up were French, German, and Spanish.

The results of previous years are as follows :—

Year.	Number Examined	Passed.	Failed.
1902	280	202	78
1903	456	324	132
1904	540	375	165
1905	681	502	179
1906	644	469	175
1907	629	476	153
1908	615	467	148
1909	656	506	150
1910	642	495	147

These examinations are held at any of the Society's centres where the necessary arrangements can be made, at any date convenient to the local committee. The examination includes dictation, reading, and conversation, and is so arranged as to test efficiency in a colloquial knowledge of the language, without laying too much stress on minute grammatical accuracy. Candidates who are reported upon as highly qualified by the examiners receive a certificate of having passed with distinction.

The examiners are Mr. S. Barlet and Mr. B. M. Nevill Perkins for French, Professor H. G. Atkins and Professor A. Johannson for German, Professor R. Ramirez and Mr. W. F. Bletcher for Spanish, and Mr. Luigi Ricci for Italian.

XVI.—The Society's Medal.

In 1849 permission was obtained from H.R.H. Prince Albert, who was then President of the Society, to use his head on the Society's medal, and a die for the purpose was made by W. Wyon. This medal was employed up to 1861. After the election of King Edward VII., then H.R.H. the Prince of Wales, to the Presidentship in 1863, his head was placed upon the obverse of the medal, the die being also made by W. Wyon. In 1900, the old die being worn, a new die was engraved at his Majesty's desire by Mr. Emil Fuchs. In 1901, when King Edward succeeded to the throne, and became Patron of the Society, he acceded to the request of the Council that his head should still appear on the Society's medal, and this was done, the necessary alteration being made in the inscription.

On the accession of King George V., when he resigned the Presidency and became Patron, he was asked by the Council if he would allow his head to be engraved on the medal. His Majesty graciously consented, and expressed his wish that the work should be executed by Mr. Bertram Mackennal, A.R.A. Mr. Mackennal has prepared an excellent model of his Majesty's profile, and a die is now being made from this by Mr. Allan Wyon.

XVII.—William Shipley's Tomb.

In the course of some investigations which were being made by the Secretary into the history of William Shipley, to whose exertions was due the foundation of the Society, it was brought to his notice that Shipley's tomb at Maidstone, in the churchyard of All Saints, was in an extremely bad state, and at the suggestion of Mr. J. H. Allchin (Chief Curator of Maidstone Museum and Public Library), and of Mr. Herbert Monckton (Town Clerk of Maidstone), he asked the Council to authorise its repair. This has now been done at the Society's expense.

An account of Shipley was included in the article on the foundation of the Society, which appeared in the *Journal* of the 9th inst.

XVIII.—Conversazione.

The annual conversazione of the Society was held, by the kind permission of the Trustees of the British Museum, in the galleries of the Natural History Museum, South Kensington, on Tuesday evening, May 30th. An account of the conversazione appeared in the *Journal* of the 2nd inst.

XIX.—New Council.

In accordance with the By-laws, the following Vice-Presidents retire by seniority :—Sir William Abney, Sir Steuart Colvin Bayley, Colonel H. C. L. Holden, and Sir Aston Webb. H.R.H. the President has nominated Sir Steuart Colvin Bayley for election as a Vice-President, and also the Duke of Abercorn and the Lord Chief Justice, who were nominated by King Edward and King George when they were Presidents of the Society. To fill the four vacancies, the Council now propose Sir William Lee-Warner, who is already a member of the Council, the Hon. Sir Charles Fremantle, Sir John Wolfe-Barry, and Sir Westby B. Perceval, all of whom have seen long service on the Council and retired last year.

There are four vacancies among the ordinary Members of Council caused by the retirement of Mr. T. J. Bennett, Mr. W. C. Knight Clowes, Sir William Lee-Warner, and Colonel Sir Colin Scott-Moncrieff. To fill these vacancies the Council suggest the names of Mr. William H. Maw, a Past-President of the Institution of Mechanical Engineers and also a Past-President of the British Astronomical Association; Mr. George Ranken Askwith, C.B., K.C., Comptroller-General of the Commercial, Labour and Statistical Departments of the Board of Trade; Mr. James Swinburne, F.R.S., Past-President of the Institution of Electrical Engineers, who

delivered a course of Cantor Lectures before the Society on "Applied Electric Chemistry" in 1896, and also read a paper on "The Nernst Electric Light" in 1899; and Dr. Henry A. Miers, F.R.S., Principal of the University of London, who, as far back as 1896, gave the Society an excellent course of Cantor lectures on "Precious Stones."

None of these gentlemen have served before on the Council in any capacity.

XX.—OBITUARY.

The list of members whose death during the past year the Society has to deplore is much shorter than usual. Several of the deceased members had served in past years on the Council. Earl Spencer, who was elected a member in 1879, became a Vice-President in that year. He was Chairman of the Joint Committee of members of the Royal Commission for the Paris Exhibition of 1878 and the Society of Arts, which organised a series of reports by artisans on the Exhibition. Sir Charles Dilke was a very old member of the Society, for he was elected in 1857 when he was a boy of thirteen. At that time his father and his grandfather were both members, and two years later his younger brother also became a life member. He was on the Council in 1869 and 1870. He read two papers before the Society, and on several occasions presided at its meetings. Another past member of the Council was Mr. H. Graham Harris, who became a member of the Society in 1883, and was elected on the Council in 1896. He served on the Council, with one interval, till 1908, and in 1889 he gave a course of Cantor lectures on "Heat Engines other than Steam." The Society is indebted to Mr. Harris's liberality for the excellent portrait, painted by Mr. Seymour Lucas in 1904, of Sir Frederick Bramwell, Bart., who was his partner.

Others of the members who died during the past year had read papers before the Society, or served on its committees. Sir Charles Elliott read two papers before the Indian Section, one on the Prevention of Famine, and one on the 1901 Census. He was a member of the Indian Section Committee, and a frequent attendant at the meetings of the Section. Sir Caspar Purdon Clarke read papers on "The Domestic Architecture of India," "Street Architecture in India," "Modern Indian Art," and "English Brocades and Figured Silks." Mr. James G. H. Glass read a paper in 1896 on the Land Slip at Gohna. Mr. Thomas Casson read one on Organ Design in 1903, and Mr. George H. M. Batten one on the Opium Question in 1892. Sir Clifton Robinson in 1902 read a paper on Electric Traction. Mr. Alexander Rogers was an old member of the Society, which he joined in 1878, and from 1892 he served on the Committee of the Indian Section. He seldom missed a meeting of the Section, taking part in the discussion on many occasions. Sir Francis Galton joined the Society in 1876, and in 1890 he read before it a paper on "Physical Tests in Competitive Examinations."

Mr. Dorabjee Cama, the head of the Parsi community in London, joined the Society in 1871, but he never took any active part in its proceedings. Sir William Agnew was a member since 1898, and Mr. Alfred Huth since 1883. Mr. Edward Pillow did much excellent work in the cause of technical education in the northern and eastern counties of England, and took part in the discussions at the International Congress on Technical Education in 1897.

The Society suffered the loss during the year of one of its Honorary Corresponding members —Mons. Georges Berger — who was elected when he was General Commissioner for the Paris Exhibition of 1889.

Notices of the above-named, and other members of the Society who died during the past year, will be found in the columns of the *Journal*.

XXI.—FINANCE.

The annual statement of receipts and expenditure was published—in accordance with the usual practice—in the *Journal* last week. It shows the revenue and expenditure for the financial year ending May 31st last, the Assets and Liabilities of the Society, its Investments and the Trusts standing in its name.

The CHAIRMAN (Sir John Cameron Lamb), in moving the adoption of the Report, said as it was the last occasion on which he should have the honour of appearing before them as Chairman of Council, he should like to take the opportunity of very cordially thanking his colleagues for all their kindness and consideration. It would have been quite impossible for him to have done the work without their support and the kindly assistance which they had extended to him on all occasions. The members would see from the Report that during the past session they had had a most excellent series of lectures and papers, and on several occasions additional interest was given to the paper by the presence of very distinguished men in the chair, whose remarks had been most valuable, and had added greatly to the interest of the meeting. The papers had ranged over a very wide field. None of them had been uninteresting, and some were of very high merit

indeed. He said Sir Henry Trueman Wood, the Secretary, had added to their obligations to him by his researches into the early history of the Society. The results of those researches were extremely interesting, and were calculated to increase their pride in so old and honourable a Society. They would have noticed that the membership roll included such men as Earl Howe, Admiral Anson, Admiral Rodney, Lord Clive, Reynolds, Hogarth, Goldsmith, Johnson, Boswell, Gibbon, and William Pitt (Earl of Chatham). He referred to the fact that it had been a record year for honours conferred by his Majesty upon Members of the Council of the Society, and cordially congratulated the recipients. He also thought it was a pleasant coincidence that the Society's Albert medallist for the present year —the Hon. Sir Charles Algernon Parsons—should receive a public honour (the K.C.B.) within two or three days of the announcement of the award, and thought, perhaps, it might be taken as a confirmation, if any were needed, of their choice of so eminent a man for the highest honour that the Society could bestow. The revenue of the Society did not go up by leaps and bounds. Still, their financial position was better than it was last year, which he considered was satisfactory. He regretted that it had not been possible to take any practical steps towards providing better accommodation for the work which the Society carried on there, but he hoped that an early successor in the office of Chairman would have a chance of bringing forward proposals with that object. He could not conclude his words of farewell without calling attention to the invaluable services which the Lord Chief Justice (Lord Alverstone) had so willingly rendered the Society, and asked the members to bear those services gratefully in mind in adopting the Report.

Sir William Henry White, K.C.B., LL.D., Sc.D., F.R.S., seconded the adoption of the Report, which was then agreed to.

The Chairman proposed a cordial vote of thanks to Sir Henry Trueman Wood (the Secretary), Mr. G. K. Menzies (the Assistant Secretary), Mr. S. Digby (the Secretary of the Indian and Colonial Sections), Mr. George Davenport (Chief Clerk), and Mr. J. Buchanan (Accountant), and to the other officers of the Society for their services, and was pleased to think that their able Secretary was supported by such a devoted staff of officers.

Sir Owen Roberts, M.A., D.C.L., LL.D., said it gave him great pleasure to second the resolution, which was carried unanimously.

The Secretary, in returning thanks for this expression of confidence in himself and in the other officers of the Society, acknowledged his indebtedness to Mr. Henry B. Wheatley, the late Assistant Secretary, in the work on which he (Sir Henry Wood) was then engaged in connection with the early history of the Society. Mr. Wheatley had accumulated a great store of knowledge from the old records of the Society from the time of its foundation. He said he had always felt that such a history should be undertaken by one who was familiar with the work of the Society, although he was finding out that their predecessors often did not record the very facts which were most wanted at the present time.

The ballot having remained open for half-an-hour, and the scrutineers having reported, the Chairman declared that the following had been elected to fill the several offices. The names in *italics* are those of members who have not, during the past year, filled the office to which they have been elected.

President.

H.R.H. The Duke of Connaught and Strathearn, K.G.

Vice-Presidents.

*Duke of Abercorn, K.G., C.B.
*The Lord Chief Justice of England, G.C.M.G., F.R.S.
*Sir Steuart Colvin Bayley, G.C.S.I., C.I.E.
Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.
Lord Blyth.
Earl of Cromer, G.C.B., O.M., G.C.M.G., K.C.S.I., C.I.E.
Sir Henry Hardinge Cunynghame, K.C.B.
Hon. Sir Charles W. Fremantle, K.C.B.
Lord Curzon of Kedleston, G.C.S.I., G.C.I.E.
Sir John Cameron Lamb, C.B., C.M.G.
Sir William Lee-Warner, G.C.S.I.
Hon. Richard Clere Parsons, M.A.
Sir Westby B. Perceval, K.C.M.G.
Sir William Henry Preece, K.C.B., F.R.S.
Sir Boverton Redwood, Bt., D.Sc., F.R.S.E.
Sir Owen Roberts, M.A., D.C.L., LL.D.
The Earl of Rosebery, K.G., K.T., D.C.L., F.R.S.
Lord Sanderson, G.C.B.
Alexander Siemens.
Hon. Sir Richard Solomon, G.C.M.G., K.C.B., K.C.V.O., K.C.
Sir William Hood Treacher, K.C.M.G.
Sir William H. White, K.C.B., LL.D., Sc.D., F.R.S.
Sir John Wolfe-Barry, K.C.B., LL.D., F.R.S.

Ordinary Members of Council.

George Ranken Askwith, C.B., K.C.
Henry Taylor Bovey, M.A., LL.D., F.R.S.
Dugald Clerk, F.R.S.
Alan Summerly Cole, C.B.
William Henry Davison, M.A.
Robert Kaye Gray.
Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.
William Henry Maw, M.Inst.C.E.

* Nominated by H.R.H. the President.

Principal Henry A. Miers, D.Sc., F.R.S.
James Swinburne, F.R.S.
Sir Philip Watts, K.C.B., LL.D., D.Sc., F.R S.
Colonel Sir John Smith Young, C.V.O.

TREASURERS.

Carmichael Thomas.
Professor John Millar Thomson, LL.D., F.R.S.

SECRETARY.

Sir Henry Trueman Wood, M.A.

On the motion of the CHAIRMAN a vote of thanks to the scrutineers was carried unanimously.

Sir STEUART COLVIN BAYLEY, G.C.S.I., C.I.E., proposed a hearty vote of thanks to Sir John Cameron Lamb, not only for presiding on the present occasion, but also for the care he had bestowed on the work of the Council, and for the ability with which he had guided the affairs of the Society during the past year. He was sure that they all regretted his relinquishment of the office of Chairman of Council.

The motion was put to the meeting, and carried unanimously.

The CHAIRMAN acknowledged the vote of thanks.

The meeting then adjourned.

THE ARTIFICIAL SEASONING OF TIMBER.

The amount of timber seasoned by artificial means increases every year, and this is not to be wondered at when it is remembered that wood so treated may be prepared in as many weeks as the natural process takes years. Nor are the results of the artificial process, if carefully managed, inferior in any way to those of the natural operation. Indeed, it is claimed that timber artificially dried absorbs less moisture from the atmosphere than that which is dried naturally.

A great amount of technical skill is required in the management of the drying-kilns. Dry, warm air would crack and twist the green timber. In the early stages of drying, the air must be saturated with moisture, and only dry in the final stages. The arrangement of the most modern kilns is described in the Engineering Supplement of the *Times* :—

"A long closed-in building, capable of holding several thousands of cubic feet of timber, say from 20,000 ft. to 50,000 ft., has a floor laid with rails sloping gently from the end at which the timber is loaded in on trucks to the end opposite, where it is discharged. At one side of the building next the discharging end a fan draws in air over the surfaces of a steam heater, and sends it warmed into that end of the building, whence it traverses along to the loading end, passing in its course between the boards or planks, which are separated about an inch apart by narrow strips of wood laid across at intervals of about two feet. The moisture in the timber is taken up by the warm air first at the discharge end of the kiln, and is deposited again on the timber at the loading end. Thus the saturation of the air increases in its passage from one end to the other, and its volume, intensity of pressure, and temperature diminish also. Entering the kiln as a dry, warm current, it leaves it as a moist, cooled current. The effect on the timber is to remove moisture from the piles at the discharge end and to deposit moisture on those at the entering end; it is taken, therefore, from the timber which is driest and yielded up to the timber that is greenest. In less-pronounced degrees the same process is going on all through the length of the kiln.

"The reason for this practice is as follows:—Green timber, being heavily charged with water and sap, would, if subjected to a warm, dry atmosphere, dry off rapidly on the outside, leaving the interior wet—a condition which is termed case-hardening. The inside would dry in course of time, but it would shrink and crack in doing so, producing the familiar 'shakes.' But if it is saturated with warm air which is heavily laden with moisture, the latter opens the pores right to the centre and prevents them from shrinking, and this is the preliminary stage which is accomplished at the loading end, before any drying-off at all is done. So important is this that in the case of green, hard woods, when they are put into the kiln without any preliminary air-drying, it is usual to subject them to a previous steaming in a separate compartment adjacent to the drying-kiln to ensure thorough saturation. In natural seasoning there is a parallel to this, when balks of timber are floated in running streams for several months with the object of leaching out the sap by the action of water, which water can be easily removed subsequently with less risk of cracking the timber. A similar result is sought when small blocks of hard wood are boiled in water to remove sap and hasten drying.

"In the kiln the trucks of timber are moved forwards at intervals as often as a fresh truck is loaded in, moving towards the discharging end. They are thus brought gradually under the influence of drier air less charged with moisture. The result is that the timber dries from within outwards, with the *minimum* of 'shakes' possible, until, as it arrives at the discharging end, it is subjected only to currents of dry, warm air."

THE PRODUCTION OF HONEY IN CUBA.

The production of honey in western Cuba, as in all other sections of the country, has been an established industry for many years, and is now carried on with more or less vigour, and under conditions which, to some extent, resemble modern methods. The bee, which thrives in Cuba by reason of climate and the abundance of the practically perennial flora, has been developed into a comparatively good stock, the native bees having

been supplanted somewhat by the southern European and American-bred varieties. According to the United States Consul in Habana, this improvement of bee-stock has not been entirely the result of effort in recent years, as the Cubans for generations have imported bees. However, before the advent of the American, bee-keeping in Cuba was in a decidedly primitive state, the hives being makeshift affairs, and very often royal palm-trunks. As the great majority of the honey was sold in strained bulk, and the wax melted down, these crude hives served the purpose in most cases. When the American and other foreign settlers began to come to Cuba, and some of these perceived the opportunity in bee-keeping, modern appliances began to appear, and now the use of the modern hive is well established with both natives and foreigners. There has also ensued better management of apiaries, and as a result there has been an expansion of colonies and a greater production of good honey. Therefore the apiary in Cuba which in the present day has any pretensions towards size and good conditions, may have one hundred to five hundred colonies all housed in good hives, and producing in a season as much as two hundred pounds per colony. The processes of collecting honey in Cuba differ in no essential particular from those in the United States. The hives, as has been stated, are now usually of the American variety, and so also are the various implements employed. The honey is generally brought to the market in strained form, this process being effected at the apiary. The containers are barrels, and the wax is received in moulded form. For strained honey, the average price in the Habana market is from one shilling and eightpence to two shillings a gallon, and the wax from one shilling and threepence to one shilling and eightpence per pound. These prices are a distinct advance on those of two years ago, and therefore have somewhat stimulated the industry. The exportation of honey and beeswax from Cuba now constitutes an important financial item. According to the official statistics for the year 1909, there was exported of honey a total of 9,726,663 pounds, of which the United States is said to have taken 4,140,077 pounds, and Germany 2,773,863 pounds. According to the same statistics, the exports of beeswax amounted to 1,623,353 pounds, of which the United States is said to have taken 697,577 pounds, and Germany 787,788 pounds. Of the total exportation of honey and beeswax the port of Habana has about 75 per cent., this being due largely to the fact that Habana merchants buy the bulk of the production for exportation.

HOME INDUSTRIES.

The Coal Trade.—The strike in one portion of the Welsh coal-field continues, notwithstanding that the Miners' Federation of Great Britain has refused to organise or authorise a national strike of miners. The matter in dispute—namely, the rate of wages payable for working in abnormal places—hardly seems to warrant the loss and misery occasioned by this prolonged industrial conflict. The present position of the coal trade does not suggest that this is a very opportune time for quarrels between masters and men. Coal shipments from Scotland and the north of England have gained by the Welsh disturbance, but even with this assistance the coal exports from Scotland up to the middle of June show a decrease of over 45,000 tons as compared with the corresponding period of last year. Collieries are so short of orders that Lanarkshire coalowners are considering a scheme for the curtailment of output. Prices are said to be unremunerative, and there is little likelihood of their improving, for year by year German competition becomes more formidable. Germany continues to take a considerable quantity of English coal, but the demand is diminishing, and in the markets British superiority is no longer uncontested. Nowadays it is price, not brand, which usually settles the contract. Consumers who used to use Welsh or Newcastle coal, whatever the price, are no longer insistent upon it, owing to the improvement in the methods of consumption. And the consumption of mineral oil as fuel continues to grow. These are factors which warrant some anxiety as to the future of the British coal export trade, but apparently they do not weigh with the Welsh miners on strike.

Synthetic Rubber.—It must be a long time before synthetic rubber seriously affects the price of rubber, but it has to be reckoned with. Dr. Gerlach has been giving his views on it before the Rubber Commission recently appointed by the German Colonial Agricultural Committee, and they are worth noting. In the beginning Dr. Gerlach was sceptical as to its value, and was very much surprised when bulk samples satisfied him that synthetic rubber possesses the essential properties of high-grade material. To what extent the new product will compete with natural rubber remains to be seen. The raw material of synthetic rubber is itself a manufactured article, the production of which, on a large scale, can only be undertaken by a few chemical firms, but there can be little doubt that artificial rubber will eventually appear on the market as a commercial product. Dr. Gerlach thinks that makers will take care that the output is not on a scale sufficient to depress the price of rubber. However that may be, producing costs will have to be largely reduced before serious competition with natural rubber is possible.

Scotch Whisky.—Attempts are being made by some of the larger holders of Highland malt whisky to form a combination, with the object of holding for higher prices. The necessity for some such combination has arisen from the apparent intention of the big blending firms to buy up the stocks. The holders of very old Highland malt whiskies are now few in number, although with

strong financial resources. Having lost heavily over their investments, they naturally want to secure more reasonable prices for the balance of their stocks. The suggestion is that each member of the proposed combination should turn his stocks into it at a certain fixed price and contribute capital in proportion, making up the total to £500,000. The stocks so pooled would be held for a price representing an advance of at least 1s. 6*d.* per gallon on the present range of values. Whether the scheme will come to anything remains to be seen. The proportion of the stocks controlled by the combination, and the extent of the dependence of the big blenders upon the old Highland malt whiskies, must be amongst the determining factors.

Hydrogen Peroxide.—The *Manchester Guardian* has an interesting reference to this bleaching agent, which is manufactured by the action of sulphuric acid on barium superoxide. Barium peroxide always contains traces of iron, manganese, aluminium, and other metallic impurities, derived from the heavy spar from which it is made, and in the process of manufacture these impurities naturally pass over into the hydrogen superoxide. They bring about the rapid decomposition of the peroxide during the concentrating operations, so that their previous removal is necessary; and it is by no means a simple matter. Attempts to work out some other process have proved fruitless until quite recently, though it has long been known that small quantities of the compound are formed when a mixture of hydrogen and oxygen are exploded by means of an electric spark, the principal product of the reaction being, of course, water. This was not considered a very promising field for investigation, but it is now reported that a German chemical firm have overcome the technical difficulties and are producing hydrogen peroxide by a modification of this method. The plant consists of a gas-holder, a number of glass silent discharge tubes through which the gases pass and where they are subjected to the action of the current, a pressure and vacuum arrangement whereby circulation is effected. The gas mixture comes from the holder, goes through the tubes, then passes on through water, which absorbs the peroxide formed, the remaining gases going forward to another holder where the proportions are readjusted. The mixture is brought to the requisite standard and then again treated, so that the process is a continuous one. Alternating current at 8,000 to 10,000 volts is employed. The peroxide is marketed as a 3 per cent. solution —the usual strength. Hydrogen peroxide is used in fairly large quantities for bleaching ivory, bone, and feathers, as well as in the bleaching of textile fabrics and for various other purposes. Its value is due to its action as a powerful but harmless oxidising agent.

The Telephone Transfer.—Last week the Postmaster-General moved a resolution, upon which the Telephone Transfer Bill will be founded, to enable the Government to pay for and take over the telephone system at the end of this year. As the Government and the Company cannot agree upon the value of the system, the matter is to be submitted for decision to the Railway and Canal Commission. It will be remembered that in 1905 the Government agreed to purchase all plant, land, and buildings of the National Telephone Company in use at the date of the agreement, or constructed after that date in accordance with the specifications and rules contained in the agreement, subject to the right of the Postmaster-General to object to take over any plant not suited to his requirements. In the event of disagreement as to price, it was to be fixed by the Railway and Canal Commissioners, as arbitrators, on the basis of the "then value," exclusive of any allowance for the past or future profits, or any compensation for compulsory sale or other considerations. It will be noticed that the agreement follows closely upon the lines laid down by the Tramways Act of 1870, and it can hardly be said to err on the side of liberality. The late Mr. W. E. L. Gaine, the general manager of the Company, stated before a select committee that in the view of the directors the bargain was a hard one, because it gave no consideration in respect of the goodwill of the business, with its gross income of over £2,000,000 per annum, and its net revenue of over £750,000, which the Company had built up. The Company had had to pay for all the experiments and mistakes which are inherent in the launching and developing of any new industry. On the other hand, the Association of Municipal Corporations and the London County Council considered the terms of purchase to be too favourable to the Company.

The Cotton Supply.—The acreage reports show that the area under cotton this season is the largest in the history of the United States, although not as large as was expected by many. The increase is mostly in the extreme south-west. In Oklahama, on account of two bad corn years, the farmers have turned a considerable acreage into cotton. In Louisiana and Mississippi, acreage that had been abandoned on account of its being infested with the weevil has been planted this year, the farmers believing that the rest the soil has had will have had an effect. The size of the crop is more dependent upon the weather and the weevil than upon the acreage planted, and the reports of the condition of the crop are very favourable; but Texas and Oklahama are said to be suffering from heat and want of rain. The acreage reported, 35,004,000 acres, compares well with the revised figures of last year, 33,418,000 acres, which was the largest acreage ever reported up to that date. The trade consider that there is an indication of a possible 14,000,000 bale crop. As for the weevil, it usually does its damage from the middle of July to the end of the season.

Cotton Goods.—It is assumed in some quarters that the relatively lessened consumption of raw cotton means that we are losing our supremacy in

the cotton trade, but many causes have combined to bring about the lessened production of coarse yarns, with a proportionately smaller consumption of the raw material. Better wages and a higher standard of living amongst workers have produced modifications in the goods required by the home trade, and these goods are now manufactured with a lessened quantity of raw cotton for a given yardage. Great changes have taken place in the character of the goods sent out. Heavy "grey domestics" and heavy bleached "Croydons" have almost ceased to be used, being replaced by lighter and smarter goods, requiring less raw cotton to produce. It is the same with the "fustian" trade. Cotton cords, union cords, and moleskins have been replaced by the woollen cloth of Yorkshire, which is at once warmer and smarter. Then again, heavy cotton sailcloth for the use of vessels, for which there was a large demand a generation ago—a material made from heavy coarse yarns—used up much raw cotton, but the demand for sailcloth has now almost disappeared. Similarly the growing use of lamps, gas, and electric light has almost destroyed the need for candlewicks. And there are other heavy cotton goods that have almost ceased to be made.

The Insurance Bill.—It has often been pointed out in these Notes that legislation intended to benefit, among others, the very poor and dependent, has sometimes injured them, and it may be feared that the Insurance Bill, if passed in its present form, will not be an exception to this melancholy tendency. Take Clause 51. It is not to be supposed that it will pass in its present form, but unless amended out of recognition it will make it more difficult for the old and weak to obtain house-room. Given certain conditions, the clause would make it impossible to enforce the payment of rent for twelve months in the case of illness. How would that work? It would make it almost impossible for the aged, or those who appear to be in ill-health, to become tenants. For where is the landlord who is willing to run the risk of having to keep a tenant for a year before he can eject him for non-payment of rent?

NOTES ON BOOKS.

BIRD-FLIGHT AS THE BASIS OF AVIATION. By Otto Lilienthal. Translated from the Second Edition by A. W. Isenthal, A.M.I.E.E., F.R.P.S. London: Longmans, Green & Co. 9*s.* net.

This volume has been compiled from the results of numerous experiments conducted by the brothers Otto and Gustav Lilienthal, and a biographical introduction has been added by the latter, which gives a brief but very interesting account of the man who—if we exclude the very doubtful claims of Icarus—may be regarded as the first martyr to the science of aviation. From early years the attention of the brothers was devoted to studying the flight of birds, especially of the storks which were very numerous in their German home; and as soon as they could scrape together a few thalers they invested them in palisander sticks and willow canes, with which they constructed gliders. So successful were these that from a sandhill fifty metres high Otto finally contrived to make glides up to 350 metres in length.

During the whole course of his life Otto Lilienthal devoted every spare moment to his favourite study, and the more he experimented the more he became convinced that "the only possibility of attaining efficient human flight lies in the exact imitation of bird-flight with regard to the aerodynamic conditions, because this is probably the sole method which permits of free, rapid flight with a minimum of effort." The airmen of to-day have departed far enough from the ideals of Lilienthal, but there are not wanting a few who seem to think that the flying machine of the future may yet revert to something more resembling those ideals than our present aeroplanes. Be that as it may, no student of aviation can fail to be interested in this volume, and in the experiments of one who was certainly an original thinker and a fearless pioneer.

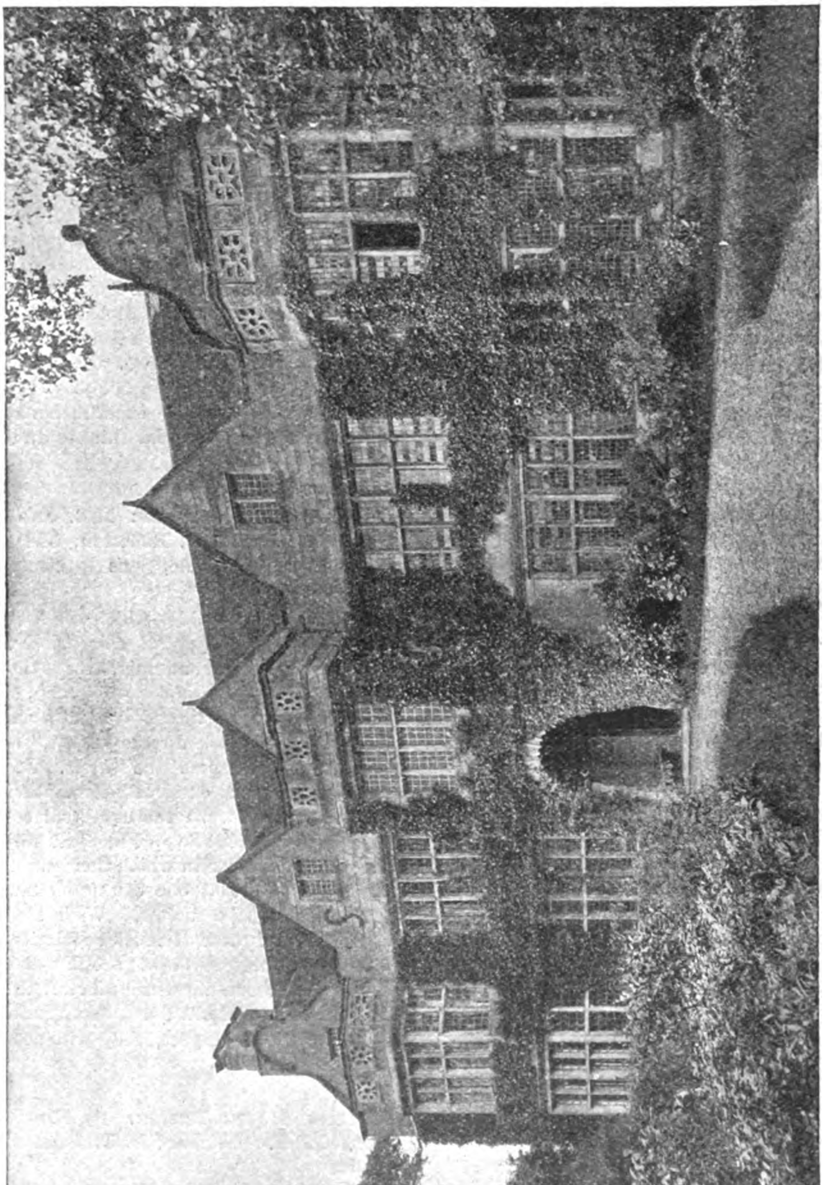
ON WRITING THESES FOR M.B. AND M.D. DEGREES. By H. D. Rolleston, M.D., F.R.C.P. London: John Bale, Sons & Danielsson, Ltd. 1*s.* net.

In this little pamphlet, which was first printed in the *St. George's Hospital Gazette*, Dr. Rolleston gives hints, which one might have hoped would be superfluous for any educated man, on "how to find a subject for a thesis," "what a thesis should be," "how to work up the subject," and how to arrange and compose the thesis. At first sight this strikes one as extremely elementary, and it is only when one recalls the continual complaints of examiners in scientific and medical subjects, as to the deplorable style in which their candidates write their answers, that one can understand the need for reprinting the article. With some brilliant exceptions, however, it must be admitted that the average literary style of the English man of science leaves an immense amount to be desired, and if Dr. Rolleston's words do anything to mend matters in this respect, they will not have been written in vain.

ENGLISH HOUSE DESIGN. By Ernest Willmott, F.R.I.B.A. London: B. T. Batsford. 10*s.* 6*d.* net.

Although a considerable number of books on English domestic architecture have been published in recent years, these are for the most part large, technical and costly, so that there is ample room for a volume like Mr. Willmott's, which contains, in a handy, compendious and inexpensive form, a brief analysis of some of the best specimens of English houses from the sixteenth to the twentieth century. The book is divided into five chapters.

The first deals with the house and its setting, and contains some useful suggestions as to the treatment of the site and its influence upon the design of the house. Chapter II. treats of the chief principles of house design, *e.g.*, proportion, scale, colour, texture, etc. Chapter III.—the longest and most interesting section—is concerned with the old English house, and its gradual development. Chapter IV. discusses in general what Mr. Willmott calls "the Revival," and in particular the work of Philip Webb, Bodley and Garner, and R. Norman Shaw; while Chapter V. contains a considerable and exceedingly encouraging selection from contemporary designs.



ST. JOHN'S, WARWICK.

The author will probably be the last to resent the statement that the chief charm and value of the book lie in the illustrations. There are 150 of these; they have been selected with great taste and care, and they include specimens of every type of house, from the large country seat to the cottage, from the sixteenth century to the present time. The courtesy of the publisher has made it possible to reproduce two of these. The first represents that charming old manor, St. John's, Warwick,

which, one is pleased to notice, has been rescued from the decay which threatened it a few years ago, and restored to its old-time beauty. The name of the architect is unknown, but the house dates probably from the early half of the seventeenth century; with "the regularly ordered projections of the bays, alternating and contrasting with the flat walling between," and the beautiful soft grey colouring of the stone, it forms one of the finest specimens of the manor house in this country, and offers the most pleasurable surprise to one who comes upon it quite unexpectedly in the somewhat prosaic outskirts of Warwick.

The second illustration represents the house, "Orchards," near Godalming. It is the work of Mr. E. L. Lutyens, one of the most original and successful of our present-day domestic architects. Mr. Willmott includes no less than five illustrations of this house—one being a ground plan, two exterior views, and two interior—and no one will think that too much space has been given to this charming building. A good deal of attention is also deservedly devoted to the work of Mr. R. Norman Shaw and Mr. R. S. Lorimer. In connection with the latter it is interesting to notice from the illustration of his manor house at Barton Hartshorn that he appears to be as much at home in work characteristically English as in the Scottish style, with which his name is more generally associated.

" ORCHARDS," NEAR GODALMING.

Mr. Willmott and his publisher have produced a volume which must be eagerly welcomed by all interested in English domestic architecture, and which should certainly be consulted by those who meditate building a country residence, whether a mansion or a cottage.

GENERAL NOTES.

THE PROPORTION OF THE SEXES IN ENGLAND AND WALES.—According to the 1911 Census, the excess of females over males in England and Wales was 1,178,317, the numbers being 18,626,793 and 17,448,476 respectively. In 1801 the proportion of females to males in this area was 1,057 to 1,000; it then declined until 1851, when it stood at 1,042 to 1,000, but for the next fifty years there has been a slight but continuous increase in the proportion. In 1911 it was the same as in 1901, viz., 1,068 to 1,000, but when due allowance is made for the number of males absent in South Africa during the war, there can be no doubt that the true proportion of females to males was somewhat lower ten years ago than it is to-day. There is considerable difference in the sex distribution of the population in different parts of the country. In Monmouthshire the proportion of females to 1,000 males is only 912; in Sussex it is 1,218.

THE RAILWAYS OF THE UNITED KINGDOM.—A return issued by the Board of Trade, giving statistics relative to the railways of the United Kingdom in 1910, shows, amongst other data given, the following:—Length of line open for traffic, 23,387 miles; authorised capital, £1,399,275,000; paid-up capital, £1,318,469,000; passengers carried (exclusive of season-ticket holders), 1,305,633,000; minerals conveyed, 404,825,000 tons; general merchandise, 190,263,000 tons; trains travelled 423,156,000 miles; total gross receipts, £123,889,000; net receipts, £47,297,000; and working expenditure, £76,592,000.

MOTOR-CULTURE IN FRANCE.—Under the auspices of the Association Française de Moto-culture, an important show of agricultural machinery will be held at Melun (Departement Seine-et-Marne) from the 2nd to 9th July next. This show, which promises to be one of the most important of the kind yet held in Europe, will comprise ploughing machinery driven by motors or electricity, haymaking machines, reaping, harvesting and threshing machines, as well as wagons for agricultural puroses worked by motors. There will be a special section for freezing machinery, and machinery for the production of acetylene-gas for farm purposes. Conferences will be held during the week on motor-culture and on other branches of up-to-date rural economy.

THE UNITED STATES SILK INDUSTRY.—According to the American Census returns, the growth of the silk manufactures of the United States has been as follows for the series of years given: 1870, £2,500,000; 1880, £8,300,000; 1890, £17,500,000; 1900, £21,500,000; 1905, £27,000,000; while it is estimated that the returns of production for 1910 will run considerably over £30,000,000. The number of silk establishments has increased from 67 in 1850 to 624 in 1905. In keeping with the increase in the silk establishments, there was a corresponding increase in the imports of the raw material to supply these establishments. For example, the value of the raw silk, which amounted in 1870 to £600,000, rose to £13,700,000 in 1910. In addition to the latter figure, silk waste, to the value of £400,000, was imported, and a considerable quantity of spun silk or schappe yarn.
